## GRAMMAR.

GRAMMAR is that knowledge of words which qualifies the possessor for speaking and writing with propriety. PARTICULAR GRAMMAR comprehends the rules of particular languages, as founded on the practice of those who have that sort of conspicuousness in society which is considered as entitling them to fix the standard in each. Every language has thus a grammatical system of its own. All languages, however, possess some circumstances in common. Prevalent analogies are developed in their origin and history, and certain leading principles are found to obtain in the application of them to the purposes of speech. The general doctrines discovered by the comparison of different languages form the important science of PHILOSOPHICAL, or UNIVERSAL GRAMMAR.

### UNIVERSAL GRAMMAR.

THIS science unfolds the principles by which man is directed in the contrivance of the varieties of words. Its utility is extended by the opportunities which it gives of tracing the connection which the phenomena of language, considered as a production of the human mind, have with the other principles of our nature.

As the term Grammar has been currently applied to a much inferior department of knowledge, some have thought proper to give Universal Grammar the apparently more elegant designation of the THEORY OF LANGUAGE. This latter designation, however, comprehends all the general branches of inquiry connected with language, which are treated under various articles of this work, such as ALPHABET, ETYMOLOGY, PHILOLOGY, and LANGUAGE. Its most interesting branch consists of those inquiries which, under the name of UNIVERSAL GRAMMAR, we here propose to lay before our readers.

Language being the leading instrument by which men communicate their thoughts to one another, it is to it that we undoubtedly owe the most important improvements of which our intellectual character is susceptible. It might therefore have been expected that an inquiry into its nature would necessarily imply an elucidation of all the laws of thought. But its province does not extend altogether so far; and, by keeping it within its due bounds, we shall do greater justice both to this science and to those with which it is connected. We shall find that the points of view in which man appears in thinking and in speaking are not so perfectly identical as has been imagined. It is not true that Universal Grammar implies the whole theory of human thought; yet it implies a great and important part of it: and the habit which the study of it gives us of investigating the subject, and the analogies which it furnishes for the prosecution of the rest, may, under judicious management, contribute materials towards a perfect knowledge of the general philosophy of mind.

We have intimated that this science originates in the comparison of different languages. It is not indeed very flattering to the pride of human intellect, and it will appear to many inaccurate, as well as undignified, to ascribe the discovery of the principles of Universal Grammar to a circumstance which might be regarded as accidental, viz. the multiplicity of languages existing among mankind. Its principles must operate in the formation of each individual language; and the science might therefore appear to admit of being investigated with sufficient certainty, by a direct inquiry into the operations of the human mind, or by the obvious analysis of any single language. This might be thought sufficient to distinguish all that is requisite to the purposes of speech from every thing whimsical or peculiar, that is, from those turns of words and of phraseology which ought to be reckoned idiomatic. It might, at least, seem reasonable to expect that the principles would be discovered by paying attention to the variations and analogies existing among those words of any language which are not immediately and evidently borrowed from a foreign source. It might even be thought possible to collect them by recording the early operations of a child in learning the use of his native language. That the principles of this science *could* have been so discovered, it would be rash to deny. But the well known obstructions opposed to science by the delicacy and proneness to error which mark the human faculties, and the various external biases which the mind receives, operate in all ages to prevent scientific inquiry from being made, and in corrupting the accuracy of the results obtained. Hence we are sometimes indebted to fortunate accidents for an introduction to the right path of inquiry, and for the discovery of truths which had otherwise a chance of remaining for ever unknown. One of these fortunate accidents, as relating to the subject of our present article, is the existence of various languages in the world, and the access which individuals have to compare them together. The success which philosophers have met with in these inquiries has arisen from the study of languages the most diversified from each other in their structure. Those of ancient Greece and Rome have, for example, been compared with those of modern Europe, and both these with the languages of the East, and the great differences apparent in their origin and structure have afforded a valuable opportunity of tracing, with a scientific hand, the general operations of man in this conspicuous department of his active efforts. An extensive erudition in literature confers emancipation from that enthralling influence, which any single language exercises over those whose knowledge is confined to it. The errors which the habits of one would produce receive correction from the attention exacted by the varying genius of another. These inquiries might even lead us a step higher. They might enable us to discover whether or not there are any circumstances in which the habits common to all languages mark a prevailing erroneous bias in our nature, and might lead us to improve and purify in this department the perspicacity of our intellect.

The difficulty of the subject renders it at least prudent to avail ourselves of all the aids which can be afforded by diversities in the structure of languages. These, indeed, are of themselves elegant subjects of study. No person who cultivates them can be indifferent about Universal Grammar, or insensible to the intimate connection which exists between the two pursuits. A very limited fact in philology not unfrequently suggests an important doctrine in the philosophy of grammar, which is afterwards confirmed by multiplied evidences, and, though formerly overlooked, exhibits, when known, a character of internal truth, and throws a broad light over the whole extent of the subject.

In no circumstance does the difficulty of this subject appear more conspicuous than in the diversity of sentiment which prevails on it. This diversity is indeed capable of being represented as chiefly, if not entirely, verbal. But, where verbal differences are pertinaciously adhered to, some misconceptions with regard to the subject itself are undoubtedly more or less prevalent. It cannot be said to be clearly understood among all who cultivate it, unless they either agree in the choice of the words by which their theories are expressed, or concur in acknowledging their differences of phraseology to be immaterial.

This is not at present the case. The cultivators of the science are divided into parties, which seem so distant from one another, that the philosophical analysis of language may be considered as still in its infancy. The account which we shall now give of it will not arrogate to itself the rank of a system matured for indiscriminate adoption. It will only be offered for deliberate consideration, as an attempt to advance the progress of this interesting branch of study, by exhibiting explanations which will show to partial systems several of their leading defects, and reconcile a variety of disputes without compromising the spirit of investigation.

## CHAP. I.

### *On the Object or Universal Office of Language.*

In order to investigate the characteristic differences by which words are distinguished, it is essential that we entertain correct ideas of the OBJECT or PURPOSE of language. Grammarians have hitherto satisfied themselves, with describing it as consisting in the COMMUNICATION OF OUR THOUGHTS. Yet it does not appear certain that they have always entertained the same views of what is meant by this communication. Vague notions of the office of language have in consequence been entertained, and a confusion arising from this cause has impeded the inquiries which were made into the origin and distinctions of the various parts of speech. Mr Harris describes it as consisting in "an exhibition of the energies or motions of the soul." These he divides into perception and volition; and he considers every sentence as either "a sentence of assertion," or "a sentence of volition." Some consider the object of language as simply consisting in the exhibition of a connection betwixt one idea and another, and therefore make the act of AFFIRMATION its universal office. These opinions, though slightly varying, agree in stating the communication of our thoughts to be the object of language.

That we may divest the subject of ambiguity, we shall enquire in what respects thought is ever communicated by language; what are the circumstances that lead to such communication; and whether or not the importance of this object entitles it to be regarded as the sole and definite purpose for which it is formed and employed.

Men may evince, by various signs, that particular thoughts occupy their minds. This is not only done by pantomimical language, but by oral sounds constituting the materials of verbal discourse. We sometimes shew by involuntary exclamations that we are affected by certain impressions called passions, which, though they originate from outward causes, do not necessarily point to such causes in our mode of expressing them. At other times, words are employed as the signs of external objects which are known to the person addressed. The effect of the employment of these is to recal to his recollection ideas formerly possessed by him. We show, at the same time, that they occupy our own minds. The meaning of the words being formerly known, they exhibit nothing new, except their connection with some present occasion. Old ideas thus recalled, however, do not constitute exactly the same state of thought which accompanied the former employment of the words. The mental exercises excited by the same word at different times are not strictly the same. They cannot be identical, because they are separate instances of mental exercise. But they are not even perfectly similar. Amidst the varying movements of the human mind, in which one thought impels another, and in which external and internal causes modify the state of the percipient being, the appropriate affection produced by any particular word can never be separately obtained. It is always modified, either by humour, by degrees of activity in the mind, or by the kinds of exercise in which it has been previously engaged.

The most important modifications of the mental effects of words arise from their connection with one another. By changes in this connection, new conjunctions of ideas are presented to the mind of the person addressed. The signs of thoughts formerly known to him are so exhibited as to excite impressions possessing the most striking novelty, and imparting the most important character, both to the immediate thoughts of the individual, and to those which are liable to occur on numerous future occasions. This is the case when, by means of words well understood, and therefore conveying in their separate state no idea that is new, we communicate information to one another, and exercise an influence on human opinions. On this office of language depends the whole benefit which mankind derive from the records of literature and science.

Engrossed by this most dignified application of language, authors have been induced to consider it as consisting entirely in assertion; that is, in expressing the connection of one idea with another, and conveying by these means new information. But, it may be called in question how far this account is strictly applicable to all language, or may be trusted for our guidance in tracing the steps of its earliest history.

It has been hastily assumed, that language arises from an original and universal inclination to impart our thoughts gratuitously to one another. From this cause it has sometimes been erroneously concluded, that it is nothing else than a faithful transcript of the successions of human thought. This, however, is not its character. A man does not speak simply because he thinks. It is not a necessary result of the possession of a thinking faculty, nor does the inclination to speak regularly accompany its operations. It is the effect of a range of thoughts, which must be considered as limited when compared to the whole phenomena of mind. Speech, like every other voluntary act of man, is founded on the presence of particular motives. It originates in his social nature taking advantage of his social state; and it depends on the knowledge which each has of various links of connection existing betwixt himself and other thinking beings.

It is not natural to man to communicate all his thoughts. Supposing, therefore, that a complete analysis of the origin of thought were in our possession, this would not necessarily bring along with it a perfect theory of the origin and character of language; nor would the most perfect history of the formation of language lead us in the opposite direction to a perfect analysis of the nature of thought.

But, allowing that we do not by means of language communicate *all* our thoughts, that we make a selection among them suited to our several occasions, it might still be contended that we do *nothing else* by means of language than communicate our thoughts; that this is its universal office; and that this position might be assumed as fundamental in entering on the subject of universal Grammar.

Some considerations will, we conceive, warrant us in hesitating before we concede even this point. We shall not stop to enquire if there is any acceptation in which this theory is true; but it is certainly susceptible of a meaning which is erroneous, and which has tended in some cases to distort philological enquiry. On the supposition now mentioned, language would still be considered as properly an exhibition of human thought.*

The first observation which we have to make on this account of the subject is, that, if it were correct, language ought always to have a definite reference to our sentiments, and ought in fact to express them with fidelity. But we find that, when we desire a person to perform any act, our motives for it are kept out of view, and are not intended to be contemplated by the individual spoken to. The motives which are expected to operate on him are ideas of a different sort which we endeavour to excite. Even in the use of the plainest affirmations, we do not necessarily exhibit our own thoughts. We may excite thoughts completely the reverse of them. This is always the case when we procure reception to a false proposition. The thought conveyed by our words has indeed been revolved in the mind as a contrivance for operating on another. In that other, however, we mean to produce a particular belief. This is certainly a thought; yet it is not the belief, consequently not the thought, which, in so far as truth is concerned, we ourselves entertain.

It might indeed be replied, that this employment of language is unnatural; that it is as much a deviation from its original purpose, in the right use of our faculties, as any act of drivelling folly committed by means of language, which ought not to be regarded as entering into its original character. But it is to be remembered that this use of language, though disingenuous, is still characteristic of intellect and address.

It might also be said, that in this use of language we closely *imitate* the sentences in which our own ideas are *bona fide* communicated, and that our success in falsehood depends on the closeness of this imitation. This fact only shows that dissimulation does not affect language in its structure. But its *object* must imply the real motives of the speaker. This account of it, therefore, must be deficient. If we can form a general theory on the subject which will embrace these as well as all other occasions on which it is used, a material advantage will undoubtedly be obtained.

The existence of false sentences is not our only reason for declining to regard the communication of thought, at least that communication which consists in assertion, as the universal office of language. We shall find that *Imperative sentences* cannot, without great awkwardness, be reduced to affirmations or communications of our knowledge. But, reserving that argument for the next Chapter, we shall now endeavour to unfold, in a more detailed manner, some of the intricacies in which this part of the subject is involved.

Different circumstances concur to impress the philosophical inquirer with an idea, that the communication of our thoughts is the object of language. One, at which we have already hinted, is, that this communication is the object of a *great part* of language, perhaps by far the greatest. This is most especially the case in polished and literary communities. It is the object of the greater part of the language of men of philosophical habits, the only persons who concern themselves with analytical inquiries on the subject; and it recommends itself as exhibiting the most important species of influence which language has exerted on society.

There are also some particulars in which all human speech agrees with the office of communicating thought, and which have led to an acquiescence in that account of its general object. One is, that the use of it always proceeds from some thoughts existing in the mind. Another is, that language consists of the signs of thought. A third, that the thoughts corresponding to these signs are contemplated by the individual using them. And the last is, that language terminates in exciting thoughts in the person addressed. But, though these points of coincidence are real, a closer attention will, we think, convince our readers, that they do not of themselves constitute a communication of our thoughts.

The mere circumstance that the employment of lan-

* For a more varied illustration of this and some other views nearly coinciding with those which are here expressed, we refer to a paper on "the theory of language," contained in the 7th volume of the Transactions of the Royal Society of Edinburgh.

guage is in every instance the effect of previous thought is by no means peculiar to this department of human exertion. All our voluntary actions are as much the effect of our mental operations as the uttering or the writing of sentences. In the use of language, as in other exertions, we indeed execute our own designs; but the enquiry is still equally open as before, what is our specific design in using language?

The second circumstance essential to language, which has perhaps tended to confirm the notion that its specific object is to communicate our thoughts, is, that the signs of human thought form the materials of which language consists. Such signs are always the media employed when we communicate our thoughts to one another. Yet it may be inquired, whether they admit of being also applied to other uses, and whether the object of language is, on that account, still more general?

The third circumstance of which we took notice, that the thoughts of which our words are the signs are entertained by the individual using them, is little more than a condensation of the two former, and requires no separate observation.

The truth will evolve itself in the clearest light when we discuss the last particular in which language has one common character with the communication of thought, that it produces appropriate thoughts in the mind of the person addressed. This is always the intention of the speaker, and if it is used by him in a skilful manner, the production of such thoughts is the consequence. This object is much more general than the communication of our own thoughts; but it is not too general to be stated as the real object of language. The conveyance of our sentiments, volitions, and opinions, is only an important part of it. The definite object of language consists in THE PRODUCTION OF THOUGHT BY MEANS OF ORAL SIGNS.

By adopting this more comprehensive view of the subject, we avoid all difficulty about the nature of such sentences as are the reverse of the belief of the speaker. We avoid the necessity of any inquiry into the propriety of considering them as in some sense exhibitions of the thoughts which he entertains for the moment, or as partial representations of his habitual thoughts. We consider them, in common with all sentences, in a point of view in which they maintain the same unquestionable ground; that is, as instruments fabricated to execute our designs; and our universal design in language is, to produce in one another such mental impressions as we please. Its ulterior purposes, being considerably diversified, admit of subdivision.

## CHAP. II.

### *The General Nature of Sentences.*

According to the author of the Diversions of Purley, two parts of speech are necessary to language, the noun and the verb, and every sentence must contain both. The reason assigned for this is, that one part of speech is required as the sign of the idea, and another as the instrument of communication. The views which this author entertained of the characteristic nature of the verb, and the act of communication as distinct from the exhibition of the signs of ideas, are not fully developed in his writings. We have not, therefore, sufficient data for appreciating their merits. The opinion maintained by some of his most acute followers is, that affirmation is the proper character of all sentences. This is considered as closely connected with the doctrine which makes the object of language to consist in the communication of our thoughts; and by this communication seems to be understood, the act of conveying to our neighbours the same connections betwixt ideas, (formerly known to both,) which they possess in our own minds. This conveyance, and the act of affirmation, are reckoned equivalent. Affirmation, from *ad firmare*, means the establishing of a connection betwixt one idea and another. The doctrine which resolves language into assertion does not depend on the truth of the theory, that its object is the communication of our thoughts. Our readers will perhaps agree with us in denying that sentences intended to deceive are communications of the thoughts of the speaker. It must, however, be allowed by all, that these sentences are assertions, and the inquiry still remains open, whether or not assertion is the proper character of sentences? To this inquiry the present Chapter is devoted.

A sentence of assertion includes two ideas expressed by two signs, and another sign to indicate the affirmation, or the establishment of their mutual connection. In the sentence "man is rational," "man" expresses one idea, the first two syllables of the word "rational" another, and the last syllable of "rational" along with the word "is" constitutes a sign expressing the connection betwixt the two. These different signs are not always expressed in separate words. Sometimes two of them are contained in one, as in the last word of the sentence "John walks." Sometimes all the three are contained in a single one, as in the Latin word *loquitur*, for "he speaks;" or *rubet*, for "he is red."

On a full consideration, however, of the variety of arrangement which words assume in the use of language, and the various kinds of words employed, assertion does not appear essential to it. We may produce thought without making any assertion. We may, for instance, merely call the attention of another person to an object formerly known to him. A very extensive department in the uses to which it is applied is that of exciting the person addressed to the performance of voluntary acts. This is done by *Imperatives*, which certainly differ from assertions. Attempts have indeed been made to reduce them under this head, and to regard them in the same light with those affirmations in which an abbreviation is produced by condensing a plurality of signs into one. This attempt succeeds in so far as it appears to establish a fact, that, according to the habits of speaking and understanding one another which we now possess, the same meaning may be conveyed by an affirmation and by an imperative sentence. The sentence, *I nunc et versus tecum meditare canoros*, is of the same import with the affirmative sentence, *Jubeo te nunc ire et tecum meditari versus canoros*. But the question recurs, which of these modes of expression is likely to have been the original one in the contrivance of words?

We formerly observed that the contrivances of language are founded on the known relations existing, on different occasions, betwixt the speaker and the person addressed, and are so adapted as to enable the former to avail himself of these relations for accomplishing some definite purpose. An answer to the inquiry, what forms of sentences are likely to be the earliest and the simplest, is not obtained by determining what connections of thoughts are simplest in relation to the mind of the solitary individual, but by finding what those purposes are which he is likely soonest to have in view in employing the influence which language gives him over others.

The first objects that strike the attention of man in becoming acquainted with his fellows are their motions. In other respects, one man is not more interesting to another than any piece of dead unchangeable matter. He first observes voluntary motions of the most palpable kind, and then gradually becomes acquainted with more delicate phenomena, such as the motions and changes of the human countenance, from which he infers the existence of thoughts in other persons, and judges of their nature. In acquiring this knowledge, he is guided by experience, and by a comparison betwixt the motions of others and those of which he is conscious, as the natural accompaniments of his own thoughts.

The helplessness of man as an individual, and the support which he is capable of deriving from the services of his fellows, create perpetual occasions on which he wishes for their assistance; and one of the earliest as well as the most frequent objects of his wishes is, to influence them to perform those motions for which he finds occasion. These necessities are prior to the mere luxury of a mutual communication of knowledge and opinion. This fact seems to point out imperative sentences as the earliest forms of language.

On this account, it is not historically correct to consider the imperatives *I*, *veni*, *fac*, and *dic*, as brief modes invented in the progress of language for expressing thoughts originally conveyed by means of such affirmative sentences as *jubeo* or *precor te ire*, *venire*, *facere*, and *dicere*. The act of commanding, or requesting, does not require to be mentioned. It is actually exhibited. *Jubeo te ire* is something more than *I*. It is a pleonasm in the form of an affirmative sentence; and has the same relation to this imperative which the sentence "I affirm that man is mortal," has to the shorter one, "Man is mortal." When we speak, there is no meaning in affirming that we speak; and in like manner, when we give a command, or make a request, there is no meaning in telling that we do so, unless we intend to enforce a compliance with our wishes by an additional idea contained in the verb prefixed, as by addressing ourselves particularly to the fears of another in the verb *jubeo*, or to his kindness in the verb *precor*. A command ought, in strict propriety, to be given, before it can become the subject of an affirmation.

As the imperative is an immediate consequence of our wishes, advantage might be taken of that circumstance to represent it as an "assertion that such wishes exist." But the circumstance of being the consequence of our wishes is common to it with all our actions, as well as all our words. It is rather, however, to be considered as an execution of our wishes, than an assertion of their existence. It is a call of attention; a mode of influencing the volitions of other persons, and thus producing, on their part, certain trains of action.

In corroboration of this view of the subject, we find that words signifying voluntary motion exist in the shortest form in the imperative of the verb. This is the case in all the languages, ancient and modern, which we have had access to examine. Exemplifications of this in the Latin language are afforded in the words already named, *I*, *veni*, *fac*, *dic*, and *duc*; or the common examples of the conjugations in elementary grammars, *ama*, *doce*, *lege*, *audi*. The same comparative brevity takes place in the English language, as in the words, "go," "come," "do," "say," "bring," "love," "teach," "read," and "hear," which never stand by themselves except in the imperative mood. Even when the idea expressed by any verb, in either language, is introduced as an object regarding which an assertion is to be made, the word employed is longer than the imperative. In Latin, the syllable *re* is in this case added to those which constitute the imperative. From *ama* we have *ama*-RE, and from the other imperatives, *doce*-RE *lege*-RE, and *audi*-RE; also, *i*-RE, *veni*-RE *dic*-ERE, *fac*-ERE, *duc*-ERE. In English, we prefix the word TO, or add the syllable ING; as, "*To* read, or read-*ing*, is an improving occupation." "Men of intellectual refinement delight in read-*ing*, or delight *to* read." In some instances, the word is equally short in its application to other uses as in the imperative. Of this the noun "love" is an example, being equally short, and indeed the same word, with the imperative of the corresponding verb. Such instances, however, are rare. Brevity, therefore, appears to be an original character of imperatives; a circumstance conformable with the theory, that they ought to be considered as original modes of speech, and not as abbreviations of affirmative sentences. The affirmative form, instead of illustrating the imperative mood, renders it cumbersome, and destroys its characteristic animation.

To those who have not previously considered this subject, the brevity of imperatives may appear, in point of fact, liable to some exceptions. The Chinese language is said to have no imperatives. That language, however, in so far as we can judge from our scanty knowledge of its structure, seems to owe this apparent defect to affectation and refinement, which have induced men in speaking to prepare the hearer by means of distant and respectful circumlocutions, instead of using direct imperatives, in order to avoid the apprehended indelicacy of dictating an abrupt change of direction to his thoughts. This modification probably took place after men had learned to keep their own objects and their own influence out of view, and to appear solely attentive to the convenience and pleasure of others. In a light nearly similar we are to consider those forms in the languages of modern Europe, originating in ceremony, by which single persons are addressed in the plural number.

Another question may here be asked, Why does this alleged brevity of the imperative not extend to the third person, and the plural number? Why are the words, *amato*, *amate*, *amatote*, and *amanto*, comparatively long? Would not this fact seem to intimate that the circumstance of being imperative does not of itself determine this brevity of form? To this we answer, that the word called the third person of the imperative, is not properly an imperative as directed to the person addressed; it expresses either a simple wish, or specifies some *consequence* of an action which the speaker wishes him to perform. The command is then learned by inference, and not conveyed in the word. The imperative in the second person of the plural number is, indeed, a real imperative; but it is to be observed, that it is not of so early natural origin as the imperative singular. It requires a particular arrangement to render it applicable. It implies not merely a wish that a certain action should be performed, but a knowledge that it is capable of being performed by a plurality of people, and that their concurrence in it will promote the same object, or fulfil a variety of objects that are alike desirable. Hence it probably deserves to be considered as equally remote from the original imperative with the other uses of the signs of locomotion.

Since, then, imperatives are not to be considered as contracted affirmations, it remains to inquire in what relation they stand to sentences of the latter kind? Whether these are originally two distant species of sentences, merely agreeing in the general character which is common to all language, that of being intended to produce appropriate thoughts in the person addressed?

In tracing the nature and origin of human language, it appears to us, on the whole, most strictly agreeable to the natural history of our species, to consider all language as IMPERATIVE; that is, as always implying the imperative of a verb.

Even when we merely mention an object by making use of a noun, an imperative is implied, desiring the person addressed to think of it. Some more particular intentions on the part of the speaker may be left to be inferred from the occasion on which it is uttered, or may be expressed by some circumstances of manner, or conveyed by means of some further verbal sign; but the noun itself, in the moment of utterance, always implies the general act of demonstration, that is, the imperative of the verb "look," or "think."

Assertions may be advantageously reduced to the imperative form, and may be considered as originally and essentially partaking of that character. Imperatives, we have remarked, are deprived of their characteristic animation when reduced to assertions. Assertions, on the contrary, preserve more completely that interest which originally belongs to them, when viewed as imperative directions for regulating the volitions and active thoughts of others. Our opinions proceed from impelling causes which bear a resemblance in their nature to the motives which prompt us to action, and assertions resemble the exhibition of such motives to other persons.

But if each single word possesses an imperative power, it may be asked, in what respects that power can be ascribed to the copula "is?"—When the intention of assertions is considered, this copula will be found equivalent to the imperative of the verb "believe." An opinion asserted by means of it does not retain the simple character of one which remains quiescent. Hence it is always expected to be of a nature fitted to interest the person addressed, and possessing a just claim on his attention. Without this, the declaration is regarded as unmeaning. Keeping this circumstance in view, we shall find nothing forced or exaggerated in representing the "is," in English as equivalent to "believe," and the *est* in Latin to *crede*.

When sentences constructed by means of this copula are not intended for conveying information, but for exhibiting pleasing objects already known, or objects of imagination, as in poetic description or fictitious narrative, the copula has the power of the imperative "contemplate."

One objection might be made to this theory, that *est* being placed betwixt two nominatives, cannot be equivalent to a word which governs nouns in the accusative. If such an objection should occur, it is sufficient to observe that the cases of nouns are refinements of language, intended for marking in a convenient manner certain uses of the words, and certain analogous connections which are formed among them in the composition of sentences, but that our present inquiries relate to a period of language much earlier than such contrivances; and, where the meaning can be shewn to be the same, diversities arising from these causes do not fall under our consideration.

It might, however, be objected to the whole reasoning here employed, that, if all sentences appear to be imperatives, there is no meaning in supposing those words which are usually called imperatives of verbs to be the earliest parts of speech, and in deriving from that consideration the brevity of their form. These particularities should at least imply that they differ from other imperatives. The nature and consequences of this difference require therefore to be pointed out. When we use the imperative of a verb of action, the name of the act expresses our ultimate wish, viz. the wish that the person addressed should perform it. Its name is originally contrived for this particular purpose. When we use it for other purposes, these require to be stated; and even the mere absence of the imperative use is denoted by the additional signs which we have already mentioned as distinguishing the infinitive of the verb. When we direct a person to think of objects of other kinds, each object may admit of being expressed by a very brief sign. But, for the most part, various circumstances require to be specified. Our intentions respecting any object admit of considerable latitude, and are to be particularized on each occasion by the indication of a connection betwixt that object and some others, or betwixt it and some voluntary effort which we dictate to the individual addressed. These relations, being various, require signs to distinguish them; and these signs, being generally in the form of terminations, give rise to the greater length of the words. But even in those instances in which the word used for an imperative suffers no change in its form when converted into a noun or any different part of speech, it cannot like an imperative, stand alone to form a sentence. Though not lengthened by the addition of a syllable, it requires to be accompanied by some other word.

We have maintained that every noun implies an imperative act of demonstration, or a call for attention; but it may be objected, that, as this is necessary to all language, and does not serve to distinguish one word from another, it cannot be said to be contained in the word, though implied in the act of speaking. Speech may have an imperative character, and yet it may not follow that its materials consist of imperatives alone. The names of surrounding objects may not be necessarily considered as expressive of different imperative acts, like the imperatives of different verbs. When we resolved the copula "is" into an imperative, this, perhaps, appeared an excessive refinement, and a strained attempt to give exclusive support to a particular system. It may appear sufficient for the maintenance of our fundamental theory, to keep in mind that a note of attention is implied in the act of speaking. If these views seem to our scientific readers more just than those which have been here suggested, we shall not, on so abstruse and so nice a point, urge any farther argument, but leave the preceding observations to their deliberate reflections. We have endeavoured to make as near an approach as possible to the formation of a general theory on the nature of sentences. But the views which we have given are not all essential to those that are to follow. The latter will, we hope, exhibit evidences of their own, independently of the consent of our readers to give to those contained in the present Chapter, a strict application in every particular to the parts of speech.

Language must be regarded by all as an instrument by which we direct the thoughts of one another. It has thus an undoubted imperative character, and this character receives subordinate variations, depending on the mutual relations of the speaker and the person addressed, with reference to the subject upon which it is employed. It includes four forms of influence, which have been already alluded to, and shall now be enumerated. 1st, We influence one another to exert the powers of voluntary motion. This gives rise to *Imperatives* in their acknowledged form. 2d, We direct the attention of one another to all the varieties of objects already mutually known. This gives occasion to the contrivance of *Names* to represent them. 3d, We influence one another's opinions and state of knowledge. This gives rise to the words which are particularly subservient to *Assertion*. 4th, We influence one another to communicate specific information. This gives rise to *Interrogatives*.

Though we have already given some account of the differences of words as subservient to these different uses, there are many varieties, as well as many analogies of form and use among them, which have not come under our consideration. The analysis of these will throw light on the general faculty of speech, and will furnish some rules for preserving us from mistakes in language, and from mistakes of greater importance regarding the diversified subjects to which language is applied. The remaining Chapters of this article will be occupied in investigating the differences which are commonly considered as constituting the different parts of speech.

## CHAP. III.

### *Of the Parts of Speech.*

These have been variously enumerated. Grammarians have not only differed in their arrangements, but in the number of parts of speech which they have allowed. The character of a particular language may, in some instances, determine the propriety of an arrangement in so far as concerns itself alone. The Latin language has no word exactly corresponding to the article ὁ, ἡ, το, in the Greek, and *the* in English. Those therefore who consider these words as the only definite articles in these two languages will consider the Latin language as possessing no such word; the circumstance denoted by it in other languages being left to be inferred from the connection.

But, independently of any difference originating in causes of this kind, some have called in question the propriety of certain distinctions maintained by others, whether as existing in the same language, or as common to all. Some parts of speech, reckoned by the generality to be distinct, have been ranked together by a few individuals under a more comprehensive head.

This generalization has been carried the greatest length in Tooke's *Diversions of Purley*. This author reckons the *Noun* and the *Verb* the only essential parts of speech. He does not, however, acquiesce in the views of Mr Harris, who sets out with a binary division of the subject which has the appearance of being similar. Mr Harris considers the adverb, the preposition, and the conjunction, as merely subsidiary and inferior materials, which connect the other parts of speech, and give ornament and fulness of expression to the whole; while Mr Tooke considers them, in every instance in which they are used, as equally essential with nouns and verbs, and refuses them a separate rank only because they are possessed of the same character with one or other of these parts of speech. He considers their only peculiarity as consisting in an abbreviated form, which has originated in the efforts of mankind to express their thoughts with celerity.

We have already observed that Mr Tooke founds his doctrine of the distinction of all words into nouns and verbs on this principle, that language implies "the signs of ideas," and also a "separate instrument for the purpose of communication." This separate instrument he calls the verb. He considers every verb as implying a noun, and also as implying something more, though he leaves the problem unsolved, what is that definite circumstance which, when added to the noun, makes it a verb?

We coincide with this author in so far as he maintains that language consists of the signs of ideas, together with certain contrivances for connecting these so as to answer the purposes of language. We adopt from him the valuable suggestion, that the verb contains the name of an idea, and, in this respect, comprehends the character of a noun, together with some additional circumstance; but we are obliged to give this suggestion a much wider extension, and to consider all the parts of speech, the noun itself included, as consisting of two parts, one of which is the sign of an idea, and the other a sign of a definite place which that idea is to occupy in the order of discourse Instead of saying with this author that the verb is *quod loquimur*, and the noun *de quo*, we would say that both the one and the other contain the name of an idea, and also a mark of some specific application, arising from the present occasions of the speaker. Both express certain objects *de quibus loquimur*, while the *quod loquimur* is the result of the collocation of the words thus mutually adapted

Such differences of mutual adaptation furnish the only good foundation for a distribution of the parts of speech. Great nicety in our subdivision is not essential to the explanation of their nature. We may, independently of this, point out the circumstances in which any part of speech to which we happen to give a separate name approaches to various others, or differs from them in its character. We shall therefore, without condemning the plans of others, adopt the division and arrangement which appear to us, in the mean time, most convenient. Even where a dispute may arise about the propriety of a particular distinction, in consequence of a slight difference in the obvious form of some words, which may have led to an erroneous conception of their nature, this is worthy of being noticed, for the purpose of assigning to it its due share of importance. Useful information may be derived from the detection of deceitful resemblances and deceitful differences, as well as from processes of analytical science apparently more profound. To content ourselves with showing that other persons were misled by them, and reprobating the errors which they embraced, is a plan of conduct neither fitted to promote scientific inquiry nor liberality of feeling.

## CHAP. IV.

### *Of Nouns.*

#### Sect. I. *The Nature of the Noun.*

The word *Noun* in our language, as well as the corresponding words used by grammarians in other languages, signifies "a name." Nouns are, for the most part, defined to be "words which denote *objects* or *substances*." Some consider them as including substantives and adjectives; substantives denoting substances, and adjectives denoting qualities. Others regard these two sorts of words as deserving a separate rank in language, and therefore restrict the meaning of the term "noun" to substantives. The words to which these different appellations are assigned agree in some respects, and differ in others; and the propriety of ranking them together or separately will depend on the definition given to the noun. Mr Tooke considers both substantives and adjectives as nouns, and as in fact the same sort of words, only that the adjective contains, besides the name of the object, a sign that it is to be coupled in language with some other. We shall, on the present occasion, restrict the term noun to the substantive, and shall use these terms indiscriminately, sometimes preferring the latter as better fitted to prevent any ambiguity on the part of the reader, created by the general usages of grammarians.

We may trace in the prevalent method of describing the nature of the noun, as distinguished from other parts of speech, some of the hurtful effects of the opinion entertained by grammarians, that the history of language implies a history of human knowledge and thought. Condillac maintains that languages are analytic methods, and are necessary both for giving an account of our thoughts to our own minds, and conducting us to ideas which otherwise we could not have possessed. He thinks that the investigation of them furnishes us with convenient means for the analysis of thought, and he conceives it a radical mistake to regard them merely as the instruments of communication. Conformably with this notion, that author, like many others, considers the different parts of speech as expressions for different kinds of thoughts. We hope gradually to exhibit, in the sequel of this article, an ample collection of facts in refutation of these opinions. We shall, in the mean time, illustrate their fallacy, by pointing out the fallacious character of the metaphysical speculations with which, as applied to the noun, they have been associated.

Substantive nouns have been considered as the names of substances. The word "substance," is derived from *sub* and *stare*, because they are considered as beings existing under the qualities perceived by the senses, and giving these qualities support. It is granted by every person who endeavours to go a step farther back in this speculation, that the nature of a substance, as separate from its qualities, and which metaphysicians, for the sake of distinction, denominate a *substratum*, is unknown. Notwithstanding this, such words as "stone," "earth," "wood," and "iron," are regarded not as the names of particular instances and forms of hardness, weight, visibility, colour, and other qualities which are perceived, but of substrata which possess these qualitities.

Some grammarians, following a similar theory, have represented the distinction betwixt substantives and adjectives as having for its foundation a difference existing in nature betwixt *things* and their *manner of existence.* Things are said to be substances which exist by themselves, but the manner of existence of things is said to form accidents which only exist in consequence of the existence of substances. This is the opinion advanced by the authors of the *Grammaire Generale et Raisonnée.* Words which signify the objects of thought are, in that work, distinguished into those which signify substances, and which are substantives, and those which signify accidents, and contain at the same time a notification that there is some substance to which these accidents belong. These last words are adjective nouns, or, to express each by a single word, the former are called nouns and the latter adjectives.

It is, however, an obvious fact with regard to nouns, that many of them are the names of qualities. Such are the nouns, "hardness," "blackness," and "whiteness," which have as much the character of substantives in their use in language as the words, "iron," wood," and "stone."

In order to surmount this difficulty, these have been regarded as a secondary or improper kind of substantives, and the ideas expressed by them as not originally entitled to be expressed in that form. They have been considered as originating in a figure of speech, by which qualities are treated as if they were substances. The authors of the last mentioned Grammar ingeniously attempt to solve the difficulty, by describing the qualities thus designated as *subsisting by themselves in language*, being so used as to have no need of another noun, although they are, in their own nature, mere accidents. A very little more inquiry would have led these writers to the true doctrine on the subject, that the mode of treating the sign of an idea, and the idea itself by means of it, in language, is the sole foundation of the peculiarities of the substantive noun.

The difference betwixt a substance and its qualities, and the whole doctrine of a substratum, seem to be mere assumptions of an excessively inquisitive species of philosophy. The only real objects of our knowledge are qualities. It is vain to tell us that the qualities are merely the media by which we obtain a knowledge of the substance. Our ideas of the qualities themselves are clear and precise; but we never find that our knowledge of them conducts us one step towards the knowledge of the substratum. The doctrine of the existence of the latter ought therefore to be rejected as an unfounded assumption, and the objects which we call substances ought to be considered as consisting entirely of definite assemblages of sensible qualities. We cannot, indeed, disprove the existence of a substratum, nor can we prove that this substratum is not the cause of the qualities, and the bond of their union. Nature contains riches to which the human understanding has no access. But we must have some intelligible description before we can entertain any idea of it, and we must have some proof of its existence before we can reasonably believe in it. If any person should assert that every particle of earth contains a miniature of the planetary system, we should understand his meaning, and it would not be in our power to disprove his assertion. But we should undoubtedly reject it as unsupported by evidence, and ascribe the belief of it on his part to extreme credulity, a passion for singularity, or some other of the sources of self-deception by which men are so often misled. But the doctrine of a material substratum is not merely destitute of proof; it is unintelligible. The word is pronounced without any appropriate meaning. It is not probable that a notion of this sort obtains among mankind at large. It is probable that the vulgar never think of any substratum containing the sensible qualities which they perceive, and that their ideas of matter are restricted to qualities which are the solid and real objects of their knowledge. The doctrine of a substratum has been invented by men in quest of subtleties; and it seems to have been supported by the other error already mentioned, that the structure of language exhibits an analytical view of our thoughts, and that different kinds of thoughts must be expressed where different kinds of words are used. Man is liable, in such inquiries, to give way to a precipitate curiosity, which leads him to frame hypotheses on subjects beyond his reach. He does not repose in his actual discoveries, but labours to account for what he knows; and, rather than leave this unattempted, he explains what he really knows by something which he does not know, and thus infallibly renders it more obscure. He imagines that he obtains solutions of his difficulties, while he only indulges a confused and mystic feeling associated with the use of particular words.

When several qualities are observed to be constantly united in nature, a strong association is formed among our ideas of such qualities; but if we make a careful analysis of mental phenomena, we shall find that, in pronouncing the name of any material being, certain sensible qualities, more or less vaguely conceived, are the only objects of our thoughts.

This dissertation on our ideas of substances may appear a deviation from the subject of Universal Grammar. But, since grammarians have supposed these ideas to be closely connected with the theory of nouns, it seemed necessary, in order to do justice to our subject, that we should shew the fallacy of the common doctrines from the nature of our thoughts, as well as from the structure of language. The views which we have stated lead us to no vague or perplexing conclusions. The fact of the uniformity of the definite combinations of certain material qualities, is in no degree deprived of its solidity or interest, though we decline to admit the hypothesis of a substratum. The rejection of this hypothesis will assist our physical, as well as our grammatical studies. It will relieve us from the embarrassment of the understanding, which sometimes takes place when particular qualities are found in a detached state. Those who are unpractised in the accurate exercise of thought, and have been led astray by words, have, in the outset of their physical inquiries, found it difficult to conceive that a body which is felt yet not seen, as the air, has an existence equally substantial with other matter. They have also considered light, which implies an object of sight unaccompanied by any object of touch, as on this account more difficult to be understood than earth, stones, and other substances, which are both tangible and visible. The most rational proceeding is, to satisfy ourselves with such qualities of tangibility and visibility as we can ascertain in any of their peculiarities and relations, whether they are observed in a state of conjunction or of separation.

Thus, when we attempt to trace the supposed differences betwixt substances and qualities, we find no foundation for a distinction into two kinds of objects, and much less for a distinction in the kind of terms by which such objects should be expressed. This is the same conclusion to which we are led in tracing the history of nouns. We find that the same kinds of ideas are designated by them as by adjectives.

If the distinction betwixt nouns and other parts of speech cannot be founded on the place which the objects expressed by them occupy in nature, it must rest entirely on the manner in which they are introduced with relation to the other words with which they are conjoined. It depends on the rank which the word occupies in a sentence, and which the thought excited by it is intended to occupy in that mental series which we wish to produce.

How, then, are we to define the noun, so as to distinguish it from the other parts of speech? Shall we, with Mr Tooke, consider it as the "mere name of an idea?" Shall we consider the verb as a part of speech more complicated in its nature, by containing "some circumstance in addition to the name of an idea?" And shall we be induced to extend a similar character of complication, in a smaller degree, to the adjective? This mode of proceeding might at first appear plausible. But, on closer reflection, we shall find that no word, not even a substantive noun, exists as the mere name of an idea; that there is always a demonstration of some further definite use to which it is to be applied. This we know to be the purpose of the variations called cases. Even the nominative case has a peculiarity which does not consist in the want of any such demonstration. The syllable *us* in *dominus*, denoting the nominative case, informs us that the noun is to be connected with a verb of assertion. The genitive case, and all the others, in like manner point out some definite use of the noun. If we separate these terminations, and consider them as distinct signs, and regard the radical syllables as containing the essence of the noun, (as in this example the syllables *domin*,) we shall still retain the name of the idea, but we shall have nothing to distinguish the noun from the other parts of speech. If a verb is deprived of all the parts which are intended to connect the idea which it represents with the other ideas expressed in a sentence, we shall, in like manner, retain the mere name of an object. In *domin* we have the radical syllables of the verb *dominor*, as well as of the noun *dominus*.

Taking the noun with all the terminations incident to it, we might still be supposed desirous of giving it a definition. In its different forms we have a variety of uses to which it is applied. With these in our view, we may now ask, what circumstance is common to them all, which does not belong to the same etymon in the form of a verb. It will not be easy to give a formal definition of this. It appears to us to consist in the degree of conspicuousness which the word has in a sentence, and the ascendant interest which the idea expressed by it is intended to have in the mind of the person addressed. The noun is a name for the central object of interest. When we come to consider the different cases, it will be made to appear that they refer us to degrees of importance different from one another; but they all agree in expressing ideas nearer to the central object than those expressed by the other parts of speech; or, at least, this will be shewn to be their original destination. This may seem a very imperfect definition of a particular part of speech: it expresses, however, nothing but what is true; and the same truth will be more fully developed in other instances, as we proceed with the discussion of the various kinds of words. Although no formal definition has now been given of the noun, the purpose of a definition is ultimately answered, when it is described by means of a comparison with other words, the only objects from which it requires to be distinguished.

When no termination is affixed to the radical sign, the distinction betwixt its application as a noun and as a verb is designated by its mode of connection with other words in the sentence. When the general idea expressed by the word "love" is exhibited as the chief object of interest, "love" is a noun, and the purposes of speech require it in that use to be connected with some sort of verb, as "love is a pleasing emotion." It is thus fully distinguished from the *verb* "love," which is known to be a verb from having a noun connected with it as introductory. In such sentences as, "I love," "you love," "they love," the subject of discourse is always denoted by a substantive noun. Other substantive nouns may indeed be introduced as subordinate to that which signifies the subject chiefly spoken of. The differences of these relations will be afterwards attended to. In the mean time we shall regard this general purpose as giving origin to that part of speech. In the noun the name of the idea has also greater latitude in the uses to which it is applied. It is a sign by means of which the same idea may, in the progress of discourse, be represented repeatedly, and in a great variety of aspects.

### Sect. II. *Concrete and Abstract Nouns.*

Nouns are either concrete or abstract. A concrete noun signifies a congeries of qualities habitually presented together in nature. An abstract noun signifies a quality separately conceived.

The words "man," "woman," "wood," "stone," "house," "city," are examples of *concrete nouns*. They are the same that have been considered by grammarians and metaphysicians as the names of substances, that is, of subtrata possessing definite qualities. The qualities and the substances have been supposed to be firmly conjoined; hence the name concrete, by which their nature is expressed, is derived from the Latin words *con* and *cretus*, signifying "grown together." Though the hypothesis of a substratum is rejected, the term *concrete* is perfectly well adapted to represent a congeries of qualities which have become associated in the mind, in consequence of certain specimens of them in nature being habitually found in conjunction. The name of a person well known to us suggests some or all of the qualities by which he is distinguished, such as his appearance, the sound of his voice, and the particulars of his personal character. The name of any well-known river, hamlet, field, or other inanimate object, suggests, in like manner, the distinguishing characters of each. The same thing is even done, though in a different way, by concrete terms of more general application, such as the words "river," "mountain," and "city." Sometimes one quality of the object, and sometimes several, occur to the mind as associated with the word; sometimes merely a vague impression of a scene, in which we expect to find certain qualities which are the objects of our remembrance. The limits within which the expectations connected with words of this sort are confined constitute their precise meaning, or mental definition.

The scene by which we are continually surrounded consists of groups of sensible qualities, which are various in extent, and variously combined. This diversity gives origin to a diversity of terms. Terms are rendered necessary on account of the subserviency of many surrounding objects to our first wants, and their importance as instruments of mutual assistance among men. When they are present, we may, by merely looking or pointing at them, direct to them the attention of one another, and, when they are absent, we may think of them independently of any names. But, when one man wishes to execute any purpose regarding them in their absence by exciting the ideas of them in the mind of another, he requires signs to represent them; and from the familiarity of the mind with these objects, the contrivance of names becomes a very early operation of the social individual.

*Abstract nouns* are those which signify qualities separately conceived, such as "whiteness," "roundness," "softness," "form," "magnitude," "beauty." The nature of these nouns, and of the objects which they designate, has given rise to controversy. Some have denied that they express definite or separate ideas, because qualities never exist by themselves, but are always attached to some substance; and because it is impossible even to think of the qualities without thinking of the substance. It has, for example, been declared impossible to think of whiteness, blackness, redness, straightness, or hardness, without thinking of a *thing* or substance which is white, black, red, straight or hard. In so far as this doctrine implies the impossibility of thinking of qualities without the substrata, it has been already discussed, and must be laid aside by every person who recollects that the substratum is regarded, even by those who believe most firmly in its existence, as the most difficult to be apprehended of all material objects. Those who imagine that they think about substances to which such qualities as have now been mentioned belong, merely think more or less obscurely of other qualities with which they have a strong inclination to connect those which happen to be named. Each quality is an independent object of knowledge: but the ideas of different qualities are strongly associated in the mind, and the activity and versatility of its operations produce a proneness to conjoin each one that comes into view with others conceived to be collateral. During the first evolution of our senses, our knowledge is acquired by attending to single qualities. Persons who are born blind or deaf, and consequently have none of the ideas imparted by that sense which is deficient to mingle with their other ideas, retain through life a separate conception of certain material qualities which, by the greater part of mankind, are constantly associated with others. When a person, under these circumstances, happens to recover the deficient faculty, the ideas which it conveys are at first separate, and it is only by experience that the habit of associating them with others is gradually produced. This process has been illustrated in the history of persons born blind from an opacity in the crystalline lens of the eye, and cured by a surgical operation, at a period of life when their mental faculties were so far unfolded as to enable them to describe their sensations. In mankind at large, the combinations of sensible ideas are formed long before language is attended to; and on this account the structure of language affords no analytical view of the process. If it did, the names of single qualities would be the simplest words, and the names of the assemblages which we denominate matter or substance would be comparatively compound. The reverse of this is the case. The names of habitual assemblages of objects are less compound, because the utility of assigning names to them is of prior suggestion. Single qualities are later in becoming leading subjects of discourse, and hence their names are later in assuming the form of substantive nouns. "Whiteness," "blackness," "redness," "hardness," "straightness," "roundness," are not so short as many names of objects, which comprehend one of these qualities in combination with several others. "Egg" is a shorter word than "whiteness," "soot" than "blackness." Even the names of single qualities comprehend, in their original formation, a general mark of reference to some congeries of which they are supposed to form a part, and the name is subordinate in discourse to the name of some such congeries. "White" is the name of a quality, and contains a reference to some congeries to which it is described as belonging. The separate consideration of the quality is a subsequent object of interest; therefore the term for it is of subsequent creation, and an additional sign to denote this separate consideration is attached to it. This sign is the termination "ness." From "white," we have "whiteness;" from "red," "redness;" from "round," "roundness;" from "great," "greatness." Different languages have different terminations adapted to the same purpose. From the Latin *magnus*, we have *magnitudo* in Latin, and "magnitude" in English.

Some have denied that we can have any ideas of separate qualities. It must be granted, as has been already observed, that the human mind has a strong propensity to conjoin different qualities mutually as objects of thought, and thus form conceptions of compound individuals. We mentioned, however, that it ought to be recollected, that a person whose sensibilities are only as yet beginning to be unfolded has separate perceptions of the different qualities. It is now further to be observed that any person, even one whose habits of association are most inveterate, may direct his *chief* attention to one particular quality. Others may indeed involuntarily intrude in combination with it, or he may have occasion to think of the relations in which it stands to others; but this one in particular is distinguished as the chief object of his attention, and is also thought of with constancy, while the others with which it is accidently associated are both less attended to and in themselves varying. We therefore see no impropriety in saying that this is a separate object of thought. We are certainly entitled to regard it as a separate subject of discourse. It is this alone that gives origin to such terms, and confers on them all their meaning and utility. If the present were a proper occasion for entering on such disquisitions, we might shew that even the names of concrete objects do not always excite in the mind the same constant and definite ideas, which are, on mature consideration, attached to them. When a concrete noun implies many ideas, we do not think of the whole of them. When it implies very few, we think of something else with which we suppose them to be in contact. It is seldom that the mind is occupied with the full meaning of any word, to the total exclusion of other ideas. Very little difference, therefore, exists betwixt our mode of conceiving the objects signified by concrete and those signified by abstract nouns. The comparatively complicated form of the latter arises from the comparative recency of the period at which a distinction becomes requisite, for denoting single qualities as the principal subjects of discourse.

### Sect. III. *Particular and General Nouns.*

Nouns are either particular or general. Particular nouns, or proper names, are those which are applicable only to individauls. General nouns (commonly called general terms) are those which are applied to a plurality of objects possessing a mutual resemblance.

When human knowledge becomes somewhat extended, it is impossible to conduct language by means of proper names alone. Individual objects are too numerous to receive distinct names; and, if these were imposed, it would be impossible for the most tenacious memory to retain the nouns of any language. A sense of this inconvenience has been supposed by some grammarians to have given origin to the expedient of arranging objects in genera, each genus including all the individuals which resemble one another in certain particulars, and which on that account receive one common name. Such are the words "tree," "field," "house," "bird," "horse," "elephant," "man," "woman." This history of general terms, however, is not agreeable to fact. Mankind have a *native bias* to give the same name to objects which are nearly alike. They delight to show, in this manner, that they recognise in a new object a character similar to that of something previously known. They prefer the use of words habitually significant to the coining of terms entirely new. This tendency is observed very early in children. They apply the same words, even in cases in which the resemblances of objects are not sufficiently strong to render the general application of a term satisfactory. A child introduced for the first time to the sight of an uncommon animal, such as a camel, gives it an appellation borrowed from some familiar object. First, observing its majestic size, he calls it a horse; next, the form of its head, he calls it a sheep; and, by passing from one designation to another, he shows a powerful inclination to apply to it some general term. The application of common names is always most constant where the mutual resemblances of individuals are greatest. When they are perfectly alike, it is as natural to give the same name constantly to them all as to give the same name at all times to an individual.

It has been said that all terms are at first proper names. But the name which we first apply to an object is proper only when we are acquainted with no other object resembling it, or when an individual so frequently claims our separate interest, that a name to distinguish it from all others is absolutely necessary. This last circumstance is the foundation of the application of proper names from the very beginning to all our familiar friends, notwithstanding the obvious mutual resemblances of human beings. Under other circumstances, we no sooner perceive resemblances than we form general terms, or, which is the same thing, give a general application to such terms as we possess. With regard to the greater part of nouns, it is probably nearer the truth to say that general terms are first in order, and that men, finding it convenient to designate individuals by single terms, consequently create proper names, than to maintain that a sense of the inconvenience arising from the mere multiplicity of proper names gives rise to the abridged method of forming general terms. By a tenacious disputant, it might be contended that we become acquainted with objects one by one, and that therefore, if a name is given to the first object of our knowledge as soon as known, it must be a proper name; but this speculation supposes man to form words much sooner than it is possible for him to do, that is, before he possesses any variety of knowledge; a state of things which precludes all occasion for language as well as the possibility of articulation.

Here it will be requisite to describe the nature of general ideas, a subject which has given rise to much controversy. Some have maintained that no such ideas exist; others, that they owe their existence to the previous formation of general terms. The chief argument against the existence of general ideas is deduced from the fact, that when we endeavour to think separately of the circumstance which is common to all the individuals of a genus, we can obtain no distinct image. To think of "a man in general" is said to be impossible. The man of whom we think must be tall or short, naked or clothed, fair or dark, lively or dull. In like manner, if we endeavour to form a general idea of "a tree" by contemplating nothing but what is common to all trees, the image no longer resembles any tree.

The denial of the existence of general ideas has sometimes been accompanied with a misconception, arising from the confounding of two things which are in themselves distinct; the existence of ideas in the mind, and the existence of external objects. It seems to have been tacitly taken for granted, that the same laws which regulate external objects should apply to the ideas which the mind entertains concerning them. All external objects are individuals, and therefore it has been supposed that all our ideas of them ought to be particular. External objects retain during the lapse of time their individual identity. The names assigned to them have therefore been supposed to retain one constant meaning in our minds, and this constancy has been regarded as the foundation of our ideas of particularity. Hence proper names have been supposed to be peculiarly exact in their meaning. But the fact is, that, even when we think of the same individuals in nature, our ideas at one time are different from what they are at another. They depend on the state of the mind and on the point of view which we take of the object, independently of any change to which its real qualities are liable. If particularity implies invariableness, our ideas, as existing at a specified instant of time, are the only ones that can be regarded as particular. Ideas of the same external object existing at different times, though resembling each other, may also in some respects differ; and, however nearly they may coincide, they are always distinct facts in the mind. When two ideas of the same external object entertained at different times are placed together and called one idea, this idea is general in its nature. Thus proper names have not such a steadiness in the ideas which they excite as has been ascribed to them. We shall further find that the ideas attached at any particular moment to a general term, are not so vague as has been supposed. They have a distinct character; they form a definite affection or state of mind, and that state of mind is a particular or individual fact. Individuality, however, as relating to the idea in the mind, does not form the foundation of any sort of words, because words are understood from time to time, and are considered as retaining the same meaning independently of the fluctuations of human thought. The foundation of this supposed constancy is, that the ideas attached to them have always a mutual similarity. They differ from one another, but this difference has its bounds both in proper names and general terms. The ideas attached at different times to proper names differ according to the situations and aspects in which objects are viewed, and according as the mind takes in the whole, or only a part of any object represented. It is evident that the ideas attached to general terms are subjected to the very same variations. They are also liable to variations peculiar to themselves, arising from the dissimilarities subsisting among individuals of the same genus. This cause of diversity seems to have been exclusively attended to in the inquiries instituted into the subject of general terms. Yet it is not always greater than the other. In some instances it has no effect. This takes place wherever these diversities are so slight or so void of interest as to escape observation. Such are the differences betwixt one *fly*, one *swallow*, or one *mouse*, and another. The general terms applied to these objects excite no greater variety of ideas than is liable to be excited by the proper names of individuals belonging to the respective species. It is of importance now to remark, that even general words, significant of classes of beings among which prominent distinctions exist, along with the similarities which form the foundation of the general application of the words, are to be considered as retaining from time to time the same meaning, because the ideas which they excite are variable only within certain bounds. Some definite idea is therefore strictly attached to each term. This may be considered as a detached thought, in so far as it may be made the only, or at least the leading object of attention. We may think of the objects signified by any term as one genus, and investigate their common properties. The versatile nature of the human mind makes it prone to mingle its ideas of these properties with various others, and these others are for the most part such as are combined with the character of the genus to form particular individuals. But the general property may be principally thought of, as well as solely designated.

With regard to the opinion of those who allow the existence of general ideas, yet maintain that they owe their existence to the formation of general terms, it seems to us completely incongruous. A term is invented for the purpose of expressing an idea. The recognizance of a resemblance among a plurality of individuals is the foundation of a general idea, and this always exists before any general term is invented, and before any term which was formerly a proper name receives a generic application.

The resemblances among objects have various degrees of extent. Some genera are much more comprehensive than others. Some include subordinate divisions into more limited genera. The word *genus*, as technically used in the arrangements of natural history, represents one stage of subdivision: those immediately subordinate to it are called *species*. If it is found convenient to subdivide these, the subdivisions are called *sub-species* or *varieties*. Those which are more comprehensive than genera are called *orders*. Others still more comprehensive are called *classes*. The most general division of all is into *kingdoms*, called the animal, the vegetable, and the mineral kingdom.

In the greater part of objects, however, the resemblances pass gradually into one another. One object resembles many others, each in different respects and in different degrees. Every point of resemblance and of difference has a generic name, because many exemplifications of all of them occur. In consequence of the endless variety of existing combinations, we may designate a particular object, by enumerating the general properties which meet in it to form its character. It is thus that we describe either a limited species or a single individual. This may be done without giving it an appropriate name. We never pursue a system of classification to its utmost extent, so as to give characters to all the subdivisions that might be formed. However near we have brought any two objects together by the limitations of our specific characters, it is still possible to find out some circumstance in which they differ, either in their intrinsic nature or their external relations; and, if upon this, in union with their other characters, we were to establish a term in our subdivisions, the gradations would be so much extended as to become equally numerous with individuals. Thus classification would produce no compendiousness of plan. It would give rise to as many names as there are individuals, besides encumbering us with the names of all the subdivisions. But we have no motives for proceeding in this manner. In most instances, the peculiarities of individuals, or of very limited species, do not sufficiently interest us. When they excite occasional interest, they are designated as possessing certain specific assemblages of qualities expressed by general terms, and our descriptions are aided by the employment of clear references. To designate the properties of interesting genera, species, and individuals, is a great part of the object of written language. It often happens that not only sentences but books are made subservient to the description of one object. Many others are indeed introduced for illustrating the relations sustained by the leading one; relations which undoubtedly constitute part of the character of these others, and more or less promote the elucidation of all.

The terms which designate single qualities are always general. The cause of this feature in language is worthy of investigation. The fact itself has given rise to an idea, that single qualities are not individuals; that they are mere modes applicable to different individual substances; or that, if each quality is an universal individual, it is moveable in its relations with other qualities. But single qualities, wherever they come under our knowledge, are in reality different individuals. The whiteness of snow, and the whiteness of bleached linen, are different objects. The whiteness of one piece of linen is a separate object from the whiteness of another. It is the similarity, more or less perfect, of the objects, in all instances of whiteness, that gives rise to the general name of the colour; and it is for no other reason that one common name is given to concrete assemblages of objects possessing a mutual resemblance, whether in arrangement or in kind. It is for the same reason that a plurality of objects receives the name of "stone," "mountain," or "field." Yet, however exactly coincident the colour of one object may be with that of another, and however hopeless a task it may be to attempt to distinguish them, except by the differences of their association with other qualities, the colour is in each case a separate individual. It has no proper name; because, while our attention is attracted by it, we are at the same time presented with other qualities (that is, other objects) closely conjoined with it, and it is the combined scene that fixes our attention. It is to the combined scene that we apply a name, in consequence of the joint interest which we and others take in it. The only interest that we have in marking a separate quality of this scene is, to point it out as a circumstance in which it resembles others. Hence it is only when we perceive similar objects, that we give this single quality a name. Thus the word in its very creation is general. The exactness of the resemblance which different exemplifications of single qualities have to each other is another reason why generic terms alone are applied to them. Although different objects, they are not intrinsically distinguishable, and the idea which we apply to a plurality of instances of them resembles, in its constancy, the idea attached to the same individual.

Even when any congeries of objects has a quality (or, in other words, comprehends an object) altogether peculiar, we give it no distinct name. If it is known to other persons, we refer to it by means of the concrete name by which the group of which it forms a part is known. If it is a peculiar sensation, as some of those which arise from disease, the only description that we give of it to one who has not experienced it, consists in a statement of its total dissimilarity to every other. Even when a kind of qualities belongs to a limited range of assemblages, (or, in other words, a limited species of substances,) we borrow the name of the quality from the name of the concrete assemblage of which it forms a part. The taste peculiar to an apple, an orange, a pear, or a cucumber, although forming each a peculiar class of tastes, has for its only designation a reference to the species of fruit with which it is connected.

### Sect. IV. *Etymological History of Nouns.*

The transmissions of words from one language to another are so much varied that it is not easy to trace the derivation of all. The simple sounds of which they are composed are but few; for, though the modifications of pronunciation may be infinitely multiplied, these variations do not exhibit distinctions of origin and of meaning. On the contrary, we find sounds which are very dissimilar mutually exchanged in the transmission of a word from one dialect to another. The sounds, therefore, that are inconvertible into others, or the collections of sounds which, though mutually convertible, are never exchanged for any that are different from them, are reduced within a small compass. In reviewing the history of languages, we might at times suppose that almost all sounds are mutually convertible, and, in despair of finding satisfaction from etymological researches, acquiesce in this account of them, *Les voyelles sont pour rien, et les consonnes pour peu de chose.* Such researches are most secure from fallacy, when we trace the mutual concordance of languages which are historically known to be akin. When we grasp at the resemblances among the languages of nations, which can scarcely be supposed to have ever been connected by mutual intercourse, we are in danger of mistaking for actual derivations instances in which a coincidence has accidentally taken place, amidst the sparing number of short combinations which can be produced among a few elementary sounds.

We must therefore in many cases abandon the investigation of the origin of oral signs, as concealed by the total want of documents, or other means of tracing them. In some cases, however, the natural relations of objects to certain sounds discover the origin of words; in others, an evident leading analogy enables us to trace the same radical signs through different languages. In both of these fields of research, we have an opportunity of discerning some important mental operations concerned in the formation and application of languages. We shall therefore take notice of a few general varieties in the derivation of nouns.

Some nouns shew an evident adaptation of sounds naturally connected with the objects which they denote. Whether these sounds have been received into one language from another, or owe their origin to the immediate suggestion of nature, is a matter of little moment. The principle which produces an adherence to the use of them is in both cases the same. Among these we may reckon the nouns *cuculus* in Latin, and *cuckoo* in English, evidently intended to imitate the note of the bird which they signify. The Latin *perdrix* for a partridge is a near imitation of the sound made by that bird when disturbed in the field. Of the same kind are some nouns descriptive of particular sounds. We may take for examples, the words *corn-craik* for the land rail, *pees-weep* for the lap-wing; *hubble-bubble* for a noisy smoking instrument; also such words as *hiss*, *splash*, and *splutter.* Though some of them are provincial, and others are reckoned extremely vulgar, they exhibit one feature of the tendencies of mankind in the creation of signs.

Many nouns are derived from verbs of motion. This is the case not merely with such as signify certain motions in the abstract. Many concrete nouns are also formed from such verbs, in consequence of the selection of qualities or objects to be concreted being originally suggested by some relation to the voluntary motions of mankind. Of these we have an ample list in Tooke's *Diversions of Purley.* That author seems to consider the circumstance of so many names of objects being derived from verbs as leading to important general conclusions, although these are not specified. This feature of etymology evidently arises from the interesting nature of the voluntary motions of our species. From this cause, as we have already remarked, the earliest and simplest form of words of motion is that of the imperative; a wish to receive assistance from the activity of others being the earliest motive for speech. The interesting character of these motions also appears in the prevalent etymology of names for external objects. Though the objects themselves are previously known, our first motives for contriving signs to represent them arise from their known subserviency to the directions which we mean to give to the actions of others. Their connection with these actions affords a principle by which the surrounding scene of things is divided into groups. "Fruit" is derived from the Latin word *fruor*, to enjoy, the participle of which is *fruitus* or *fructus.* It signifies "aliquid *fruit*-um," or something enjoyed.

| | |
|---|---|
| A "debt" is | aliquid *debit*-um. |
| "Rent" | aliquid *rendit*-um. |
| "Tribute" | aliquid *tribut*-um. |
| An "act" | aliquid *act*-um. |
| "Expence" | aliquid *expens*-um. |
| "Merit" | aliquid *merit*-um. |
| "Accent" | aliquid *accent*-um. |
| "Fate" | aliquid *fat*-um. |

"Alley" is formed from the French verb *aller*, to go, meaning a sort of passage. "View" is from *vû*, the past participle of the verb *voir*, to see, and signifies something seen. "Destiny," *une chose destinée.* The derivation of all these words is sufficiently obvious.

Mr Tooke has with great ability traced to a similar origin many English nouns in which it was not formerly suspected. "Spot" he derives from the verb *spit*, of which he considers it as the past participle The noun "gate," from the verb *go*, or *gae*; "road," from the verb *ride*, signifying a place that has been *rode* upon. "Head," according to him, is from *heav-ed*, and means a part elevated. "Heaven" is from the same verb, and similar in its original meaning, though different in its application. A "flood" is something which has *flowed.* "Bread" is grain, which, in one step of its preparation for food, has been *brayed.* "Weft" is the past participle of the verb *weave.* The "haft" of a tool is the part *hav'd.* A "hift" is a part *held.* "Brood, breed, and brat," are from the Saxon verb *bredan*, to cherish. "Hand" from *hentan*, to lay hold of. "Fang" and "finger," from *fingan*, to take. "Truth" comes from the verb to *true*, and signifies that which a man *tru-eth*, or believeth. "Birth" is that which *bear-eth*: "Growth" that which *grow-eth*: "Wealth" that which *weal-eth*: "Earth" that which a man *car-eth* or plougheth.

Some of Mr Tooke's etymologies, tending to the illustration of the same general remark, have been disputed; but the etymologies substituted on these occasions generally turn out to be of a similar nature, deriving the names of substances from verbs of motion.

When a concrete noun is intended to convey the impression of a connection betwixt an object and any voluntary human act, the etymology is for the most part intentionally obvious. Thus from the verb command we have the noun "commandment," for a sentence employed in commanding. From accompany we have "accompaniment;" from judge "judgment," or opinion; from invest "investment." A great number of nouns of this description, derived from Latin verbs, terminate in *tion*; as "fraction, sanction, conflagration, collision." Some terminate in *ance* or *ence*; as "resistance, inheritance, science, prudence." We have others from the same language with different terminations; as "lecture," from *legere* to read. From the English verb know, we have the noun "knowledge." Sometimes nouns are formed, by adding to a verb the termination *ing*, as "landing" from land, and "fighting" from fight. Sometimes the use of the word as a noun is not indicated by any particular sign, but merely by the scope of the sentence. The words "love," "fight," "stand," "fold," "tie," "fly," "escape," are used both as nouns and as verbs.

Nouns of a similar structure, and sometimes the very same nouns, are used to express the abstract ideas comprehended in verbs. "Government" expresses either the abstract idea of the act of governing, or the concrete ideas of a particular instance in which this act is exercised, as "the British, the American, and the Turkish governments." Even the more general expression, "a government," is concrete, while "government" is abstract. A similar two-fold application may be made of the nouns "reflection," "understanding," "judgment," "pleasure," "love," "decision," "repetition." We may speak of "love" in general as an affection of the mind; or, a swain, in speaking of his mistress, may call her "his love." We may speak of "judgment" and "reflection" as faculties of mind, or we may call the sentiments resulting from their employment, "judgments" and "reflections." It was, at one time, common in our language to employ different forms of the word on these two occasions. We had, for example, "excellence" and "dependence" in the abstract; and "excellency" and "dependency" in the concrete.

Many nouns, both concrete and abstract, are derived from adjectives. Instances of concrete nouns of this origin we have in the word "white," for the white of an egg, and in the appellation "black, or negro," for a man of a black complexion. On the same principle, articles of merchandize are called "goods." Regiments are distinguished by the designations of "the blues," "the buffs," or "the greys;" and showy persons are denominated "beaux and belles." These words denote collections of ideas, or qualities, each under a designation borrowed from one of the most conspicuous. Hence they are described by Mr Tooke as specimens of subaudition, one quality being mentioned, and the rest which form the individual understood.

Many of them approach in their nature and etymology to nouns which are derived from verbs by passing through the medium of the participle, a part of speech resembling in some respects the adjective, and often considered by grammarians as in no respect different from it.

Abstract nouns also, or the names of single qualities, are derived from adjectives. This is done in our language by the addition of the termination *ness*, as in "goodness," "whiteness," "brightness," "redness." Whether or not this termination is originally the same with the French word *nez*, signifying nose, and with the termination "ness," as applied to projecting points of land in such proper names as "Inverness" and "Sheerness," we shall not stop to inquire. Whatever is its derivation, it has the same meaning with the word "quality." Whether it was, at any former period, a separate word under a different extent of application, is a question of inferior importance. A termination regularly used as a sign has all the distinctness of a separate word, though written more close to another connected sign, and sometimes involving a greater rapidity of pronunciation.

Abstract nouns derived from adjectives belonging to other languages are various; some terminating in *tude*, as "gratitude," "magnitude;" others in *ty*, as "purity," propriety;" or in *ence*, as "prudence," "science," and "patience."

Some abstract nouns are derived from compound adjectives owing their origin to previously existing nouns. "Loveliness" is derived from the adjective "lovely," which comes from the noun "love." We have, in like manner, "faith, faithful, faithfulness;" "boy, boyish, boyishness," and many other exemplifications.

Sometimes an abstract is derived from a concrete noun, by means of a termination, as "boyhood" from "boy," and "neighbourhood" from "neighbour."

Nouns originally abstract are often applied as concretes. A female possessed of the qualification of beauty, is called "a beauty;" a person of a strange character, "an oddity;" and a curious object, "a curiosity."

Mr Tooke endeavoured to prove by the etymology of nouns that abstraction was not an act of the mind, but only an operation in language, and that the whole operation consisted in subaudition. We have found his account of the subject applicable to nouns derived from words signifying single qualities and used as designations of compound objects, while the other qualities are understood. But all these nouns are concrete. Mr Tooke does not acknowledge any difference betwixt these and the nouns which grammarians distinguish by the appellation *abstract*, such as "beauty," "elegance," and "prudence." Without even remarking that they had ever been considered as of a different nature, he includes them in the list of those which imply the operation of subaudition. He considers *providentia*, "providence," as the neuter plural of the participle *providens*, and meaning "provident things," *i. e.* expressing one quality with the subaudition of others. This subaudition is indeed more general than it would have been in the word *providens*, if such a word had been used for "a provident person." He probably considered it as a mode of contriving a word capable of being adapted to every example in which the property denoted is found. But the opinion of this author is not stated with the explicitness due to its singularity and its importance. We must confess that it seems to us totally unfounded.

We have already observed that it is in our power to make single qualities the principal objects of thought, and that no greater difficulty exists in thinking of them exclusively than in making the idea represented by a proper name, at any time, the full and only object of thought. The etymology here advanced by Mr Tooke appears in itself fanciful. Nouns in *antia* and *entia* are the only ones which give it any shadow of countenance. The genius of the Latin language does not incline to the use of other neuter plurals as names for separate qualities. In English, indeed, we say, "the agreeable," "the picturesque," "the sublime," "the beautiful," instead of "agreeableness," "picturesqueness," "sublimity," and "beauty." We also adopt the Latin expression from Horace, "the *utile*" and "the *dulce*." But whatever the etymology of the nouns called abstract may be, the manner of their signification is that which we have already stated.

### Sect. V. *The choice of Designations and the nature of the Pronoun.*

When a compound object is designated by a noun which expresses one of its qualities with a subaudition of the rest, there is evidently no reason why the same quality should always be selected for a designation. Every such object resembles in some one quality a number of others, and admits of being placed in the same class with them. In a different quality it resembles a different set of objects. Hence it may receive various general designations. The choice which we at any time make of a designation for it depends on the design which we have in view in distinguishing it from others. The same human being may be called "a man," "an African," "a slave," "a negro," or "a fool;" or he may be designated by some occasional temporary circumstance; he may be called "a debtor," "a creditor," "a patient," "a culprit," or "a witness." In using any one of these terms, we wish to call into view the very same individual, with all the parts and qualities essential to him, but designated by one of these as the most appropriate to the point of view in which the tenor of our discourse leads us to represent him. Those who regard his proper name as his chief designation will consider the others as occasional substitutes for it. But even that name may be common to him with some other men. If he has two names, (which is the case with Europeans,) a personal and a family name, he will have one of these in common with several other persons, and the other in common with a different number; and it is by the combination of the two that he is distinguished. But this very combination may happen, in some instances, to be applicable to another person equally well known to us. We must then add a third mark of distinction, such as one depending on differences of age, country, or profession. Any designation becomes completely distinctive or not according to the occasion on which it is employed. It is probably most accurate not to consider one as substituted for another, but to consider each as rendered proper on particular occasions, when a complete and interesting distinction is thus formed.

These considerations will lead us, by a direct road, to a proper estimate of the *personal pronoun*, which many grammarians have reckoned a separate part of speech, and have defined to be "a word that is used instead of a noun." Its whole office is to point out an individual by an occasional mark which distinguishes him completely from all others. It is often shorter than the name of the individual, and this seems to have led some to conceive that it is contrived for the purpose of abbreviating discourse. But it does more than this; it points out the person referred to in the most interesting temporary relation.

The *first* personal pronoun *I*, denotes "the immediate speaker" as distinguished from others by this circumstance in preference to any other character that he may bear. The *second* denotes "the party addressed" as characterised by the present circumstance of his being addressed. This character is preferred to any other that he may bear, as distinguishing him from other persons. The *third* personal pronoun has been erroneously defined to be a mere negation of the other two. This is not implied in it. When Cæsar, describing his own actions in his Commentaries, uses the third person, sometimes employing his own name, at other times *ille*, he shews that these designations are applicable to the person who speaks or writes, as well as to others, although it is most natural for all men to use peculiar words for themselves as speakers. Among some nations it is considered as treating the person addressed more delicately, and tending less to look him out of countenance, to call him *he* than *thou*. The Italians say, *Come sta*, literally, "How does he do," instead of, *Come state*, "How do you do;" and the French, in like manner, say, *Monsieur comment se porte-t-il*. A rustic girl in this country meeting a familiar friend, says, with a kind of mirthful respect, "Where is she going?" for "Where are you going?" It is also to be remarked, that a mere negation of the circumstance of being either the speaker or the person addressed would never afford a sufficiently distinctive character, and therefore could be of no use as a designation. The real office of the third personal pronoun is to designate an individual by the circumstance of "having been lately mentioned," or "much nearer to the thoughts both of the speaker and the hearer than any other who could, on that occasion, be referred to by a similar circumstance." It is thus sufficiently distinctive at the moment to prevent ambiguity.

To have a closer illustration of the nature of the pronoun, we may observe that some designations are much more durable than others. The designations "man," "king," "Dane," "Indian," "sailor," "soldier," are of a permanent nature. Some are founded on more limited external relations, and are seldom used with propriety except in particular connections, as "father," "brother," "friend," "enemy." These generally require mention to be made of the object to which the individual bears this particular relation. Others are merely temporary and occasional, as "plaintiff," "defendant," "speaker," "hearer," "buyer," "seller," "assistant," "opponent." All these words are used on particular occasions with as great propriety as the names, or any other designations of the persons spoken of. Of this last occasional kind are the words called personal pronouns. They distinguish individuals by the temporary characteristics now enumerated.

What then has led grammarians to assign to these words a separate place in language under the name of pronouns, and to describe them as possessing the peculiar character of being the substitutes of nouns?—The only circumstances in which they differ from other appellations are, that they are shorter and more familiar. Their shortness has probably made them appear unique, and their familiar recurrence has made them appear of peculiar importance. The frequency of their use, though worthy of attention, is a quality attached to words in various gradations. In this instance we have perhaps the acmé of frequency, because the pronouns are founded on the very circumstance of the use of language. Language always implies a speaker, who to himself appears important, and a person addressed, who, in order to be operated on with advantage, has a prominent interest assigned to him in our discourse.

It is probable that pronouns are of very early origin. Attempts have been made to trace the etymology of the first and second in some languages to a word signifying the hand, or some other object near and inseparable. It is sufficiently natural to suppose that persons who have words to represent such objects, and no personal pronouns, might resort to such expedients. But it is equally supposable that certain sounds might, in the very first instance, be applied to this use, on the same arbitrary principles which must have regulated the pristine application of the greater part of articulate sounds.

If no pronouns were in use, a speaker would probably point to his own body in speaking of himself, and to that of the person addressed in speaking of him. On this account some philosophers have considered it as the peculiar nature of the pronouns to be "substitutes for that pantomimical act." But the act of pointing is also used in designating other objects that are presented, especially if the speaker and hearer have no language in common.

The personal pronouns combine a great degree of generality in their use with a well-marked particularity in the instances of their application. The word *I* may be applied to any person, but only by one speaker, viz. that person himself. The quarter from which the sound proceeds determines its exact application. In the same manner *you* may be applied to any one individual, but only when the words are particularly addressed to him, and this circumstance gives us on every occasion an unerring indication of its use. *He* may be applied to any *man*, *she* to any *woman*, *it* to any *thing*, and by any individual. But they imply no reference to the present use of language. They imply some previous mention of the object referred to, and this must be well understood in order that their particular application may become intelligible. They have exactly the same meaning with the word "foresaid." Some assistance is given towards the ready understanding of their application by distinctions founded on personality and sex. The pronoun *it* is distinguished from *he* and *she* by the absence of personality; *he* from *she* by the circumstance of sex.

The term pronoun, as used by grammarians, is on the whole productive of confusion and ambiguity. It is extended to some adjectives, which are called pronominal adjectives, or adjective pronouns. Such are *ille*, *hic*, *alius*, in Latin, and *this*, *other*, in English. The word "other" has evidently the same meaning with "different," although neither the English word "different" nor the Latin word *diversus* is ever included in the list of pronouns.

### Sect. VI. *Genders.*

In the following Sections of this Chapter we shall consider some prevailing marks which accompany the application of the noun, and which adapt it to particular purposes.

As our own species comprehends the most interesting subjects of discourse, any common distinctions found among them appear worthy of being pointed out. The situation of the two sexes in society, and their general habit and appearance, afford the most remarkable distinction, and the implication of this naturally accompanies the mention of of individuals. Even when it would not be sufficiently interesting to be mentioned, provided a separate word were required for the purpose, it is sufficiently important to determine some part of the names by which persons are designated. The Greeks and Romans effected this by differences of termination. The English language has current proper names exclusively applicable to a particular sex. Similar differences are implied in the names given to domestic animals, and sometimes to animals of other kinds.

But language has not always stopped at this reasonable point. The active imaginations of those by whom it has been modified have, from vague analogies, ascribed sex to objects destitute of it. In Greek, Latin, and French, this is done in very numerous instances. In French, the genders of nouns are not easily distinguished by their terminations, yet a particular gender is uniformly attached to each, and regulates the termination given to every adjective agreeing with the noun. The details of the genders must therefore be studied by every person who wishes to speak the language with sufficient accuracy to preserve him from ridicule. These circumstances render that language of difficult acquisition.

In the Hebrew, Italian, Spanish, and French languages, there is no neuter form, so that every object must, in the syntax of words, be either masculine or feminine.

Attempts have been made to account for this prevalent arrangement, which appears in itself so absurd. But no explanation has been given that is sufficiently steady in its application to afford material assistance in facilitating the acquisition of any language. Names of objects which are masculine in one language are feminine in a second, and neuter in a third. Names of objects of the same kind, and even nouns that are synonymous, differ in their gender in the same language. Those who take pleasure in tracing these whimsical proceedings in the formation of language, will find some ingenious remarks on the subject in Harris's *Hermès*, and Tooke's *Diversions of Purley*.

The English, the Persian, and the Bengalese languages are free from the embarrassments of arbitrary genders. In English, indeed, a few objects destitute of sex have a phraseology applied to them, borrowed from sexual distinctions. But this is on rare occasions; and, as no marks of gender are attached to our adjectives, the inconvenience now stated does not occur. The whole difference in the adaptation of other words consists in the use of the personal pronouns *he* and *she*. This application of words denoting sex only partakes of the nature of poetical personification. It does not consist in such an adherence to gender as affords a basis for grammatical rules. The sun is called *he*, on the same principle on which we might compare that luminary to a king, for the splendour which surrounds him; to the cherishing father of a family; or to a presiding mind, by which extensive systems are regulated. The moon is called *she*, on the same principle on which it might be compared to an eminent female, who does not overawe by an oppressive effulgence, but diffuses a mild radiance, productive of a gentle pleasure.

### Sect. VII. *Number.*

That accident of nouns which we call *number* is a sign for representing the exemplification of a general idea in more than one individual. It does not apply to proper names. A proper name is in its nature descriptive of only one object, and therefore essentially singular. As soon as it becomes susceptible of plurality, as when we speak of the twelve Cæsars, or the seven Jameses, it ceases to be a proper name. Spain is the proper name of a country, and Spaniard has by some grammarians been called the proper name of a people; but the latter is a generic word, characterizing any one of a great number of persons by their connection with Spain. When a name is applicable to two individuals, these are to be considered as constituting a limited genus. This circumstance may not depend on any inherent character, but may be an accident occurring in the transference of proper names. The name is originally intended, in both instances of its application, to be completely adequate to distinguish an individual from all those with whom he might have been confounded. But, when the two individuals chance to meet in the same place, or to be mentioned near to one another in discourse, they must be distinguished. If the name of both is Scipio, they are to be considered as a genus coinciding in this trivial circumstance of their history, that they have received the same name.

Some nouns which are general in their acceptation do not admit of a plural, because the objects which they signify are not permanently portioned into individuals. This is the case with nouns which express such plastic materials as are capable of being easily arranged in pieces of any form or size. We have examples of it in the names of the different metals, as "gold," "silver," "iron," and "brass," words which are never used in the plural. The plural word "irons" is not applied to pieces of the metal, but to instruments formed of it. The noun "stone" is also the name of a material, of which variously shaped objects may be formed; yet it has a plural in frequent use, because nature divides it into masses which are not easily reunited so as to become homogeneous. These objects have therefore more of the character of permanent individuals. Such words as "gold," "silver," "clay," "dough," may be said to have neither singular nor plural, and to be entirely independent of number. We cannot prefix to them the word *a*, which is the sign of the singular, with any greater propriety than we can invest them with the plural form.

In most languages, nouns receive alterations in their spelling for the expression of plurality. These sometimes consist in the addition of a letter or a syllable, sometimes in the substitution of one for another. Such alterations, however, are not absolutely necessary. Number might be pointed out by separate words, or might be inferred from the connection. Many English words have no distinction betwixt their use in the singular and in the plural, such as "sheep," "grouse," and "deer." Some Latin words are the same in singular as in the plural in one or more of their cases. *Fructus* signifies "fruit" or "fruits." *Res*, "thing" or "things."

It is not easy to discover by what circumstances a community, during the formation of its language, has been influenced in choosing its mode of expressing plurality.

Some grammarians have thought that much satisfaction would be obtained, if we could always trace the plural termination to some separate word signifying a *collection*. The addition of a term of this sort is the mode of expressing plurality in the Bengalese language. *Projaa* signifies a peasant, *lok* people : and *projaa-lok* signifies peasants. The authors of Rees's *Cyclopædia* derive the plural sign in Greek, Latin, and the modern languages of Europe, from a word in the Hebrew language המון, which signifies multitude. They suppose that this word was at first subjoined to the singular word, and that afterwards, for the sake of brevity, the Hebrews designated plurality by retaining only one of the letters, *m* ; the Chaldeans, Syrians, and others, by retaining the *n*. Thus the plural was in Hebrew *-im*, in Chaldean *-in*, in Arabic *-oon*, and in Persian *-aan*. This theory further supposes the letters *n* and *s* to have had the same origin. The Chaldean *-in*, therefore, is supposed to have become *-es* in the formation of many Greek and Latin plurals. From the same source they even wish to derive the *s* which forms the plural terminations in English and French ; while the Italian language is considered as following in all nouns the analogy of the second declension of the Latin, by adopting the terminating vowel *i*. The same authors might have added, that this *i* of the Latin and Italian is the vowel letter of the Hebrew plural *im*, (ים). This vowel does not, indeed, happen to belong to the independent word המון, which they consider as giving origin to the plural sign ; but we find it used in Hebrew, not only along with the letter *m* for a familiar sign of plurality, but also by itself (י.) And it was sufficiently natural that a language derived from the Hebrew should adopt this plural sign.

This whole style of etymology, however, is questionable. It has indeed the authority of Horne Tooke's approbation. One great principle of that author was, that terminations were originally separate words ; and another principle was, that the alterations which take place in the progress of language have an abbreviating tendency. But terminations ought to be considered as equally independent signs in this form as if they were separate words ; and when any idea is of perpetual occurrence in language, as that of plurality is, it is natural to expect that the sign used for expressing it should be originally brief. Signs, however, are often changed. With some people, the mere circumstance of being long familiar renders both words and terminations of words apparently stale, and they apply themselves to the contrivance of others in their stead. These others are generally derived from sounds previously used for ideas somewhat akin.

The English plural termination may, we think, be traced with greater probability, as well as greater beauty, to a later origin than that now mentioned. Our terminating *s* seems to have arisen from a syllable which was once applied to signify a more extensive modification of the uses of the noun, and was gradually varied, in the improvement of our language, for the purposes of more precise distinction. It was anciently the syllable *is*. "Towns," the plural of town, was *toun-is*. The same syllable was also used for what we call a genitive. "Father's" was *father-is* or *fader-is*. It is only among those who are inordinately attached to the present habitudes of our language, that the termination *is*, in these two applications, will be considered as necessarily of different origin. The sign for the genitive and that for the plural are only different exemplifications of one sign, which in its meaning includes both. It was simply a term of relation synonymous with the English preposition "of," i. e. "with respect to." "Bees," for example, signifies relating to the bee ; "bees wax," wax connected with the bee ; "two bees," a repetition or doubling with respect to the bee. "Scot," is a designation for a native of a particular country. "Scotis," or "Scots," means relating to such a native. Two individuals are "two Scots ;" a "Scotswoman," a woman relating to Scot ; and, in the same manner, the word might be used in such phrases as, "the Scots court," "Scots customs," "a Scots dress." The meaning of the letter *s* in these different instances is not different : it is only general ; and, therefore, susceptible of different specific applications. Any particularity in the application intended was, in the first instance, left to be inferred from the connection ; and, afterwards, some slight differences in its orthography, pronunciation, or both, were adopted, and appropriated to the different applications. We have "Scot's" for the genitive ; "Scottish," or "Scotch," for the descriptive adjective ; while "Scots," if used at all, is restricted to the plural.

This derivation of the English plural from a more general modification of the noun will acquire confirmation, when we reflect that, in spite of the strictness of formal grammatical rules respecting the plural number, we often use the same form of the noun which denotes plurality, on different other occasions. We speak, for example, of introducing a knife "lengthways," though the way is only one. "Edgeways" is used in the same manner. The word "otherways," now changed to "otherwise," is a similar example. "Sides foremost" is a common provincial phrase in some parts of England. We speak of going "up stairs" or "down stairs," where there is only one stair, meaning up or down with respect to stair. Some of the English even speak of going "up streets" and "down streets." A boy in tossing a halfpenny calls "heads or tails," though it has only one head and one tail. If to the question, "have you any pens?" a person should reply, "yes, I have one ;" the answer would be condemned by some as ungrammatical, because one pen is not plural, and a person who has only one cannot be said to have "pens." Yet we have a constant tendency to this mode of speaking. Common sense, adhering to the powerful analogies of language, bears down the authority of formalizing systems, even in cases in which she does not possess sufficient dialectic knowledge to vindicate her proceedings. The word "pens" in this instance is merely general. It is independent of all ideas of number. It is no more restricted to plurality, so as to exclude the singular, than it is restricted to two, four, or any particular number. Had the word "pen" been used in the question now alluded to, it would have been considered as exclusively singular. But it was necessary to use one of these forms of the noun, in order to represent the genus independently of number. To prohibit the employment of any form of the noun in a manner thus general, would imply an extreme obstinacy of artificial regulation, in no degree conducive to accuracy. The want of a *separate* form for this general application of the noun, independently of number, sometimes gives rise to the following awkward circumlocutions in proclamations and legal writings : "If any *person or persons* shall transgress in the manner underwritten, *he or they* shall be subjected to the following punishments."

Another English plural is formed by means of the termination *en* as in oxen. Such plurals were much more common at a remote period of the English language. *Housen*, for example, was used for "houses." They abound in the modern German, which owes them to the same source. This syllable, like the one already mentioned, was originally of a more general application, signifying "of or relating to." The application of it which is most abundantly retained in English is for the descriptive adjective, as "wood*en*, earth*en*, gold*en*," words the same in meaning with the phrases "*of* wood, *of* earth, *of* gold." The old English language was little varied in its modifications. The syllables *is* and *en* both expressed the general circumstance of relation betwixt the idea expressed by any noun to which they were attached and some other. They were applied indiscriminately to relations of every kind, and the occasions of discourse were trusted to for the suggestion of particular ideas. A desire of improving the language, amidst the multiplicity of relative ideas which arose from intellectual improvement, led our ancestors to appropriate one termination to one subdivison of that general meaning, as well as to produce a still greater particularity, by varying the modes of writing the termination. The English thus made a nearer approach to the copious and refined languages of classical antiquity. The final *s* and the termination *en* came to signify important distinctions, *en* being used to form the descriptive adjective, and *s* for expressing various relations, including that of plurality. Wood*en* is the adjective: wood*s* is the plural. The word ox is an instance in which the *en* is retained as the plural sign, and the *is* (in ox*is* written ox's) is the genitive. We say a "drove of ox*en*" for the plural: "an ox's gall" for the genitive. Here we have a specimen of the simple but effectual expedients, to which mankind so readily recur in order to express the varieties of their thoughts.

### Sect. VIII. *Cases.*

Cases are changes of form to which nouns are subjected for the purpose of denoting annexation. Some of them are more general than others. The marks of annexation are external to the name of the object, and might therefore be expressed by separate words. But they are often attached to the name in the form of terminations. This circumstance, though not affecting their meaning, occasions a particularity of aspect in certain languages in a written state, by abridging the number of words, and also a particularity of sound when a language is spoken, because a termination is placed after the name of the object, but a preposition before it. The cases often express circumstances so general and so evanescent, that no separate word to represent them has ever been used. On this account, it is convenient, even in a philosophical treatise, to consider them in conjunction with the noun.

The *Nominative* has been represented by some as implying nothing more than the name of the idea expressed by any noun, and therefore the least complex of the cases. But it always has a reference to a verb, and this verb for the most part follows it in the same sentence. It often happens that, compared to the other cases, it is short, and that the others are distinguished by the addition of one or more syllables. Of this we have instances in the Latin nouns *vir* and *sermo*. But it more frequently happens that the nominative has a peculiar termination, and that in the formation of the other cases this is left out, and its place supplied by different terminations affixed to the radical letters. The radical letters of *dominus* are *domin-*, and the *-us* is as much a separate sign as the *i*, *-o*, *-um*, *-e*, *-orum*, *-os*, and *-is*, which form the other cases. *Dominus* is therefore something more than the name of an object. It would be contrary to the analogy of language, and of all the operations of the human mind, even the least correct, to suppose that the syllable *-us* has no original meaning. We may pronounce it a superfluity, if the definite application of the noun which it expresses can be understood without it. Yet we have no right, on this account, to pronounce it destitute of meaning. It is in fact a sign of connection with another word of definite character and use, the verb.

We have farther to observe, that the nominative gives the noun a higher rank in a sentence than the other cases. It differs from them in a manner nearly resembling that in which the noun differs from the other parts of speech. It expresses the central or focal idea, to the description of which the other words in a sentence, including the other parts of speech and nouns in the other cases, are subordinate.

The sentences which may appear exceptions to this doctrine are very numerous. This is occasioned by the general pursuit of that variety which gives elegance to language, and by the presence of other circumstances which preserve the importance due to the leading subject of discourse. By some writers the hero of a biographical narrative is mentioned in the nominative case more uniformly than by others; but by none is such a rule invariably followed. Suetonius probably follows it as often as any writer, and thus gives his biographical delineations a more concentrated force. Yet this author, in relating the death of Julius Cæsar, introduces the persons by whom he was killed in the nominative case, in preference to Cæsar himself, thus making them apparently the most important subjects for a time. Assidentem conspirati *specie officii circumsteterunt: illicoque* Cimber Tullius, *qui primas partes susceperat, quasi aliquid rogaturus, propius accessit: renuentique et gestu in aliud tempus differenti, ab utroque humero togam apprehendit, deinde clamantem, "Ista quidem vis est."* Alter Cassius *adversum vulnerat paulum infra jugulum.* 'The conspirators, under pretence of shewing 'Cæsar respect, stood up around him as he sat. Then 'Cimber Tullius, who had undertaken to commence the 'deed, approached nearer to him, with the apparent de- 'sign of making some request. As soon as he observed 'that Cæsar, by a wave of his hand, declined conversation, 'and put him off till a future time, he laid hold of him by 'the toga on both shoulders, an act which made Cæsar ex- 'claim, "This is downright force." At that instant one 'of the Cassii wounds Cæsar in the neck.' In the relation of these circumstances Cæsar might have been mentioned in the nominative case, thus: 'Cæsar was surrounded by 'the conspirators, affecting to pay him respect, was ap- 'proached by their chief Cimber Tullius, who pretended 'to make some request, and, on waving his advances, was 'seized by the toga on both shoulders; but as he exclaim- 'ed, "This is downright force," he received a direct thrust 'of a mortal weapon from the hand of one of the Cassii.' This mode of writing would keep the mind of the reader more constantly fixed on the person who is the chief subject of the narrative as a whole; but it would often render language insupportably monotonous. The author, therefore, relieves the attention of his readers, by assigning in some of his details a subordinate place to the principal personage. His importance is always maintained by the ultimate tendency of the narrative, as well as by the advantage of being more frequently than any other subject mentioned in the nominative. After the historian has, in the manner now described, varied the current of his language, he is enabled, with gracefulness as well as force, to introduce the chief subject in that mode of diction in which he will hold, by means of the nominative case, the most dignified rank in the sentence. After these details of the conduct of the conspirators, Suetonius thus proceeds: Cæsar *Cassii brachium arreptum graphio trajecit: conatusque prosilire alio vulnere tardatus est. Utque animadvertit undique se strictis pugionibus peti, toga caput obvolvit; simul sinistra manu sinum ad una cruræ deduxit, quo honestius caderet. Atque ita tribus et viginti plagis confossus est: uno modo ad primum ictum gemuit, sine voce edito.* 'Cæsar seized the arm of Cassius, pierced it with 'his writing style, then endeavoured to rush forward, but 'was prevented by another wound. Finding himself 'assailed in every direction with drawn swords, he co- 'vered his head with his toga, and, in order that he 'might fall with the greater decency, drew the lap of it 'with his left hand over his limbs. Thus he fell, stabbed 'with twenty-three wounds. He emitted a single groan 'when he received the first; but met his fate without utter- 'ing a word.' The peculiar propriety and force of these latter sentences, and a slight character of inversion, of which we are sensible in reading those which precede them, are proofs of the superior rank of the nominative case.

The *Vocative* case, or that which is used in naming the person addressed, comes next in order, not merely from its frequent coincidence in form with the nominative, but from its being probably of earlier origin in the proper names of persons than any other form of the noun. It is peculiar to nouns which designate persons, because it applies only to beings capable of hearing what is said. In these, however, it seems to be prior in the order of nature to the nominative. The Latin vocative, wherever it differs from the nominative, inclines to greater brevity. *Virgilius* was addressed *Virgili*, *Minutius*, *Minuti*, *Dominus*, *Domine*, and *Filius*, *Fili*. In this characteristic the vocative case of the noun resembles the imperative of the verb. Being the earliest use of the word, it is its shortest form.

When we enter on the consideration of the *Genitive*, *Accusative*, and *Dative* cases, especially the two last, it is found difficult to assign to each an invariable meaning, however general. In particular phrases their uses are steady; but no principle strictly universal seems to regulate their application. The most comprehensive that we can adopt is found liable to exceptions. The most likely way to discover their original meaning is, to observe the prevailing application of each, and also to enquire if there is any circumstance of application, however limited, which is peculiar to one. It is thus also that we shall be most likely to trace the species of idiom which has given origin to such exceptions as occur. Some have proceeded in a contrary direction. They have first attached to the particular case a plausible general meaning, and then exerted their ingenuity, to show that this meaning would be found applicable to instances which at first appeared most distant from it. But these modes of explanation might easily be applied to account for any possible substitution of one case for another, and therefore are erroneously considered as illustrations of a principle, while they are exceptions to a rule.

It has been common to consider the different cases as intended to express different sorts of ideas, or different relations existing betwixt the objects named. On mature reflection, we find it more conformable to the general aspect of the facts, to consider them as referring rather to the different parts of speech with which the noun is connected, and the different degrees of importance which are assigned to the idea in the present use of language. These circumstances may sometimes arise out of permanent relations; but this does not uniformly take place, and therefore the cases do not depend on them. This opinion derives presumptive evidence from the illustrations already given of the nominative and the vocative.

Our attention will be chiefly directed to cases as exemplified in the Latin and English languages. The Greek cases follow different rules, a comparison of which with those of the Latin language might suggest some interesting conjectures respecting their original uses; but they would lead us into details too extensive for the limits of this article. The Latin language, when it borrowed its cases from the Greek, deviated from the parent language in the extent which it assigned to each. A different conception seems to have been attached to the use of them. This appears in a particular manner from the addition which they have given of an ablative case, which does not depend on a subdivision of one of the others, but is in some of its uses substituted for the genitive, in others for the dative of the Greeks.

The variations and exceptions to general rules which are so often practised in the use of the cases diminish their importance in the doctrines of universal grammar. Such distinctions as they imply might have been in most instances dispensed with. The discussion of them partakes more of the character of an inquiry into the conjectural history of particular dialects, than of an investigation of the radical principles of language; and the length to which that discussion sometimes extends is due rather to the difficulty than to the importance of the subject.

The *Genitive* case, though sometimes governed by a verb, as by the verbs *potiri*, *fungi*, *meminisse*, and *angi*, sometimes by an adjective, such as *similis*, appears to have been originally applied in the Latin language to signify a relation betwixt the idea expressed by a noun and that contained in *some other noun* in the same sentence. The English preposition *of* corresponds so exactly to it, that any observations made on the one are equally applicable to the other. Attempts have been made, both by means of etymological derivations and explanations of existing phrases, to represent the word *of* as signifying some specific relation, as, for example, possession or origin. These attempts, however, have failed. We find it expressing every sort of relation that can exist betwixt the ideas contained in two nouns. This circumstance implies no ambiguity. It arises from the mere generality of the sign. When it is too general for expressing our meaning, we add some more specific ideas. In the article GRAMMAR of the *Encyclopædia Britannica*, it is justly observed that *injuria regis* may mean either "an injury inflicted by the king," or "an injury received by the king." The specific idea intended to be conveyed, must either be inferred from the connection, or pointed out by some additional sign.

The genitive case, though thus general, and supposed by some to have in the Greek language derived from this circumstance its technical name πτωσις γενικη, ought not perhaps to be considered as more general than the others. It is distinguished from them by the circumstance of being employed to show that the word put in this case is subordinate to a noun. Nothing more than a general relation betwixt the two ideas is expressed; but the connection thus established has something particular in its adaptation to the purposes of discourse. The ideas thus connected could not exchange places, nor are they of equal importance in the sentence, as they would be if conjoined by means of the word "and." "The man of virtue" and "the virtue of the man" do not mean the same thing. The ideas expressed by the words man and virtue are indeed *connected* in *both* of these phrases; but when we say "a man of virtue," it is intimated that something further is said of "the man" When we say "the virtue of the man," it is intimated that the subject on which we enlarge is "the virtue." Both of these are different from a connection formed betwixt two nouns by the word "and;" which intimates that they are on equal terms in the assertions which are made.

Such instances as we mentioned of the genitive being put after verbs and adjectives are so rare, that they may be considered as exceptions in which a stretch is made to give these governing words the power of nouns in the use of language. Every word resembles a noun in containing the name of an object or idea. It is only in relative importance in the syntax of sentences that nouns differ from other parts of speech.

Exceptions of a different kind are also found. Nouns are in some instances annexed to other nouns by marks different from those which form the genitive; e. g. *homo a secretis*, a Latin phrase for a "secretary;" and in English we have the phrases "father-IN-law," "cousin BY the mother's side." This last phrase is seldom employed without the use of the verb IS preceding it, which gives a different turn to the whole phraseology, and has the power of introducing a greater variety of words than can be annexed solely to the noun. Such exceptions as we have now mentioned are equally rare with the former; a circumstance which shews the nature of the genitive case to be almost peculiar.

In the Hebrew language, the placing of one noun after another is often the only sign of the genitive. *Jein* signifies wine, *Helbon* is the proper name of a mountain, and *Jein Helbon* is the expression for "wine of Helbon." Sometimes it is expressed in a manner which must appear remarkable to those who are not acquainted with any analogous language. The change indicating this mode of annexation is made on the governing noun, which is then technically said to be in its *constructed state*, while the noun in the genitive case undergoes no change. *Dábar* signifies word, and *Elohim* God; but there is no separate word for *of*, nor is any change made on *Elohim*, to make it equivalent to "*of* God." *Dábar* is put in its constructed state by being changed into *debár*, which signifies *word of*. *Debár Elohim* is "word of God." In like manner, *gedolim* signifies "great men," *haghir* "the city." Great men of the city is not *gedólim haghir*, but *gedolei haghir*.

In English, as has been already observed, the genitive case is sometimes expressed by the termination *s* with an apostrophe, as in the first line of Paradise Lost, "Of *man's* first disobedience, and the fruit." It is thought by some grammarians an improvement in nomenclature, to call this form of the noun an adjective of possession derived from the noun. This distinction makes no difference of doctrine. That mode of describing it seems to have been inconsciously suggested by the circumstance of its being, like the adjective in English, placed before the noun to which it is subordinate. But nothing more than the meaning of any genitive is signified by the adjective noun itself, as will appear when we come to treat of it. The English *s* has, with regard to its etymology, been considered by some as an abbreviation for *his*. But this (or the equivalent syllable *is*) is evidently an original sign in our language, at least independent of such words as *his*; and the latter is evidently derived from the pronoun *he* by having this sign attached to it.

The genitive case is sometimes expressed in English, as it is in Hebrew, by the mere juxtaposition of the nouns, with this difference, that the governed is placed before the governing noun; as in "cart wheel," "corn field," "garden wall." Some of these phrases are of more frequent recurrence than others. Sometimes the two words thus conjoined have, both in spelling and pronunciation, been run together into one, as in "timepiece," "statesman," "footman." Others of them are frequently connected in writing by a hyphen, to denote that they are scarcely to be considered as one word, yet not so much separated as two words generally are. In other instances, they are kept as distinct in a sentence as any other words. The meaning is not affected by this variety, and is so clearly expressed by simple juxtaposition in this order as never to admit of ambiguity. Here we have one fact, by the consideration of which any inordinate predilection for the individuality of words may be reduced within just bounds.

The chief ultimate purpose for which the genitive case is employed is, to add a particular circumstance for completing the description of an individual, or of a species of objects, already characterised by a term which is in itself too general for the purpose. "Man" is a general word. "A man of genius," "a country man," are instances in which the genitive is used to point out a relationship for designating a limited species contained in the genus "Man." This may be done when an individual, or a species, is introduced as the subject of discourse; as, for example, "A man of genius differs from other persons in his feelings and habits;" or it may be introduced into the predicate of a sentence, and form a part of some new assertion, as, "Bacon was a man of genius."

The other cases are distinguished from the genitive, by denoting an annexation to some part of speech different from the noun.

The *Accusative* and *Dative* have by some been considered as very nearly alike. By others some differences have been stated betwixt them, depending on differences in the objects, motions, or relations, represented by the governing word. Attempts of this last sort have proceeded on principles which served to explain a limited set of phrases, while they were totally inadequate to explain others.

The most obvious circumstance which distinguishes the *Accusative* case in Latin from the genitive is, that it is governed not by nouns, but by active verbs and certain prepositions. It is by attending to the different occasions on which it is employed, and tracing the properties which uniformly adhere to it, that we shall make the most convenient approaches to an explanation of its use.

Sometimes it represents an object to which some action or motion passes, or in which it terminates, as *Hæc studia adolescentiam alunt, senectutem oblectant*. This character, however, has been ascribed to the accusative in phrases in which it will not apply. When the verb "to love" governs the noun signifying the object of that affection in the accusative, it expresses no transition of an act. The person who is loved may be ignorant of this passion, and totally unaffected by it. When we speak of "loving all mankind," we do not speak of any action which terminates in that extensive range of objects. This remark applies to all transitive verbs, expressing emotions of mind that have a reference to external objects, as "to hate," to dread," "to respect," "to esteem." These affections may be productive of acts by which the objects of them are affected; but such acts are not implied in the affections themselves. They are excited by the objects named in the accusative, but they terminate in the individual mentioned in the nominative. To represent them as terminating in the beings called their objects, is a mere fiction: it applies only to the range of ideas of the individual mentioned, not to the actual relative energies of the different objects. Some other verbs governing the accusative are expressive of quiescent qualities, which do not affect any object different from that to which they belong. Yet these qualities imply a reference to other objects, and the mention of this reference is absolutely necessary. These other objects are put in the accusative case. Such are the verbs "resemble" in English, and *similare* or *simulare*, and *referre*, when used in that sense in Latin. Here, as no transition of any act or motion from one object to another takes place, the accusative cannot be considered in any respect as expressing such a transition. It will give but little satisfaction to say in reply, that, though nothing of this kind exists, yet it is figured in the speaker's mind, and that even in such a proposition as this, "a benevolent man loves the whole human race," we imagine a benignant emanation proceeding from the benevolent man to influence the whole species. This is an evasion of the argument. It is in like manner an evasion, rather than an explanation, to say that a person who asserts that one man "resembles" another, seems to consider such a man as influencing the state and relations of the other. This is an unconscious acknowledgment that the conceptions of the speaker, or the transitions of his thoughts, and the transitions which he studies to produce in those of the hearer, are the foundation of the use of the accusative case. This is the view which we consider as on all occasions the true one. Such mental transitions have a certain degree of rapidity, which corresponds more closely with the idea of an action terminating in an object named, than with the greater part of our associated ideas. On this account the regimen of the accusative case is more frequently applied to signify these than any other trains of thought.

When the accusative is governed by prepositions, these prepositions prepare us for a transition equally rapid with that of the active transitive verb. In order to shew that this regimen does not depend on the *idea expressed* by the governing word, we shall take this opportunity of stating a circumstance, which might otherwise appear an anticipation of our observations on the verb: to wit, that some verbs, which are completely synonymous in the ideas which they express, are totally different in the transitions of ideas which they are intended to create in the mind of the hearer. The Verbs "to speak," and "to say," signify precisely the same act. Their difference consists in this, that the verb "to speak" does not intimate an intention to state what was spoken, but the verb "say" always does. When we say "Cicero spoke," we may probably rest satisfied with mentioning the act in connection with the agent. Our hearer may, if prompted by curiosity, ask what Cicero said when he spoke? But, if we use the phrase "Cicero said," we pledge ourselves to give some account of what he said, or to subjoin the accusative of some noun, such as the word "nothing." If we do not proceed further than the words "Cicero said," the person who hears us asks the question now mentioned in a different tone: he reminds us that we have stopped short in our discourse, and have not fulfilled the promise implied in the use of the verb "to say."

The *Dative* case might easily receive a plausible explanation in a large proportion of the phrases in which it is employed. But a difficulty has arisen, in consequence of the approximation which some of its uses seem to make to that of the accusative. Some verbs which govern the accusative are synonymous with others which govern the dative. An example of this exists in the verbs *lædere* and *nocere*. *Antonius nocuit Ciceroni* is equivalent to *Antonius læsit Ciceronem.*. But though these phrases are synonymous, it is possible that the words of which they respectively consist are not equivalent. It is possible that in one of the phrases a greater share of the meaning may be contained in the verb, and less of it in the governed noun. This is rendered probable from one circumstance, that there are no verbs which admit of either case indiscriminately, so as to form with them two synonymous phrases.

We ought first to attend to those phrases in which a verb governs one noun in the accusative, and another in the dative. This may be a verb of *giving*, as in *Dedit mihi dextram*, or a verb of *declaring*, as in *Narras fabulam surdo*. One difference seems here to take place, that there is a more ready and rapid transition to the idea expressed in the accusative, than to that expressed in the dative; and the idea which is expressed in the accusative is more necessary to the completion of a significant phrase than the other. *Dedit dextram*, and *narras fabulam*, though both evidently incomplete sentences, are not quite so deficient as *dedit mihi*, or *narras surdo*. The verb is so contrived in the arbitrary application of words, as to lead the hearer to expect with greater rapidity and impatience the idea which is subjoined in the accusative, than that which is in the dative. When the dative is placed first in order, as in the phrase *dedit mihi dextram*, we are sensible of a degree of inversion, or a short suspension of the governed word most nearly connected with the verb. This mode of speech is contrived for the sake of variety and elegance, or for the convenience of dwelling on the idea expressed in the accusative, by attaching to the noun some additional parts of speech; as, *Narras mihi fabulas gigantum incredibiles*.

In the use of verbs of giving and declaring, a difference in the *actual relations* of the *object* mentioned in the accusative and that in the dative case is evident; but in verbs of *comparing* no difference of this sort is necessarily implied. The sentences, *Comparo Virgilium Homero*, and *Comparo Homerum Virgilio*, may be used for conveying the same meaning in exactly the same manner as to thought. The interest taken in one of the objects compared may not be greater than that taken in the other, and the transition made to the two may be equal in its degree of rapidity and deliberateness. At the same time, if there is any such difference of interest, it seems natural to put that object to the description of which the comparison is principally subordinate in the accusative, and the other in the dative.

These facts may furnish some illustration of those phrases in which a verb governs the dative case alone; for example, the verbs *nocere*, *favere*, *placere*, and *resistere*. The English verbs into which these are translated are equally transitive, and govern the same form of the noun, with those which correspond to Latin verbs governing the accusative. But in the Latin language it is probable that they are not so completely transitive, and resemble in their genus those English verbs to which nouns are subjoined through the medium of the preposition *to*, as the verbs "yield," and "submit." Thus the translation of *obedire* by the verb "submit" would be more accurate than by "obey," in so far as regimen is concerned, although the former of these English verbs, as applied to the expression of ideas, may be less nearly co-extensive with the Latin word. It is conceivable that a verb, which is originally not used transitively, may be more easily made to govern the dative than the accusative, whether it is employed in its simple state, or in composition. The verb *resistere*, for example, is derived from *sistere*, which signifies to stop or remain fixed, and does not prepare the hearer to expect the mention of any other object affected. This state, however, admits of being also mentioned as an impediment to the progress of another. The name of this other may be subjoined with a slight degree of ceremony; and a semi-transitive verb may be formed signifying that fixed state, together with an intention of mentioning the object impeded. The machinery of prepositions or other intervening words, for the introduction of the latter object, is dispensed with; yet the verb is made to govern a case which implies some slight degree of ceremony in the mental transition intended.

We have heard it suggested that a verb which governs a single noun in the dative implies in itself the force of a noun governed in the accusative; that *resistere*, for example, has the force of the phrase *obstaculum opponere*. Whether this suggestion has any truth in an etymological point of view, or is in any degree to be considered as a probable account of the sentiments originally attached to such verbs, we shall not stop to inquire. But a translation of some phrases, on this principle, into the English language, will afford us a clear analysis of these two cases, as well as of the verbs which respectively govern them, and yet are otherwise synonymous. The English language expresses the dative by means of the preposition *to* prefixed to the same form of the word which constitutes the accusative; just as if, in Latin, the dative case were wanting, and the meaning of it always expressed by the preposition *ad* with the accusative. This would certainly shew a more leisurely and ceremonious transition than the accusative without a preposition. Both these sentences, *Nocuit Ciceroni*, and *Læsit Ciceronem*, may be translated, "He did harm to Cicero;" but, in the first, the force of the preposition "to" is contained in the dative *Ciceroni*, and, in the last, it is contained in the verb *læsit*.

| | | |
|---|---|---|
| *Antonius* | *nocuit* | *Ciceroni.* |
| "Antony | did harm | to Cicero." |
| *Antonius* | *læsit* | *Ciceronem.* |
| "Antony | did harm to | Cicero." |

Thus the verb which governs the accusative is more completely prepared for the intended transition than that which governs the dative. This view of the cases is not, we confess, in the present instance, supported by the comparative brevity of the Latin dative and accusative, which is in favour of the dative. It depends for its proof on the use of them in language. Their comparative brevity, however, in the English language, contributes to the illustration of our views, especially as it consists in a difference of the entire word *to*, and therefore is less liable to be ascribed to accident.

The Latin dative appears, on the whole, to be appropriately employed where the verb has a degree of transitiveness intermediate betwixt those which govern the accusative and those which do not govern any case. The latter may express actions in themselves transitive, though they have not been formed for the purpose of transition, but merely for attaching the accident implied in the verb to the subject mentioned in the nominative. After such verbs the object affected may be introduced, but it requires, even in the Latin language, an intervening preposition; we say, *Lutetiam* VERSUS *contendit*, and, AD *prælium progressus est*.

The intermediate character of the dative case betwixt the accusative and the use of a governing preposition is confirmed by this circumstance, (especially as it is apparently accidental,) that, in the English language, which has no termination or peculiar form of the noun for expressing the dative case, it is sometimes expressed by the preposition *to*, and at other times by the noun in the same form which constitutes the accusative. We say "I sent a letter *to him*," or, "I sent *him* a letter." "Give *him* the money," or, "Give the money *to him*."

The *Ablative* case of the Latin language has been often considered as possessing a variety of powers. Sometimes one of these, sometimes another, has been selected as its original characteristic. Those who first assigned this case its present name have considered its original, or at least its most conspicuous application, as equivalent to the English preposition *from*, representing the object expressed by the noun as the point of commencement of motion. The author of Grammar, in Rees's *Cyclopædia*, describes it as denoting the instrument or medium by which an action is effected, and, of course, considers its meaning as most clearly expressed in such sentences as *scribo calamo*, "I write with a pen." This account of that case, however, will not apply to every sentence in which it occurs. We suspect that any detailed attempt to make instrumentality the universal characteristic of the ablative would involve the subject in inextricable confusion. The writer in the *Encyclopædia Britannica*, impressed with the hopelessness of all attempts to reduce the meaning of the ablative to any one species of relation, describes it as implying nothing more than the simple mention of concomitance. The noun which is put in the ablative may either represent a cause, an instrument, some circumstance of manner, a portion of time, or some other relation; but any one of these is inferred from the nouns employed, and from the evident mutual relations of the words composing the sentence, and not simply from the ablative case. These aids to the meaning are also rather to be regarded as limiting the generality of the case than as correcting any ambiguity. The objection to which this theory is open is, that it is too general to indicate a distinction betwixt this and the other cases of the noun. All the circumstances brought together by words in a sentence may be represented as concomitant. Something further seems necessary for the purposes of precision. The peculiarity of the ablative seems to be, that it is the only case which expresses a concomitant circumstance *by a noun alone*. It is an abbreviating contrivance for dispensing with the introduction of another verb. *Scribo calamo* is used instead of *scribo et habeo calamum*, *calamus est mihi*, or *moveo calamum*. The pen is merely mentioned in the ablative to supply the place of these circumlocutions.

In an example quoted by the last mentioned author, *templum clamore petebant*, clamour is represented only as concomitant with the action of going to the temple. These mere concomitances are called by grammarians the manner.

When we say *palleo metu*, fear is merely mentioned as a concomitant circumstance with the paleness. Yet it is intended to signify, from the natural connection betwixt paleness and fear, that the latter is the cause, and the inference is instantly made. It is because such inferences are drawn with the utmost readiness, and without any sensible interval of time, that grammarians have been deceived into the belief that the meaning inferred is fully expressed by the ablative case.

The expression of this variety of concomitant circumstances by the ablative without the intervention of an intermediate word, for the sake of connecting the noun with the preceding words, has obtained for some of its uses the designation of *the ablative absolute;* as in the phrases *Illo mortuo; Caio et Cassio consulibus*. It might be considered as absolute in its other uses, as in the annexation of cause, manner, instrument, or time. When an historian says *hoc anno floruit*, it is from the word *annus*, and not simply from the ablative case, that the idea of time is inferred by the hearer.

Attempts are sometimes made in the English language to follow the Latin idiom of using nouns in a form thus absolute; and the nominative or simple form of the noun, is employed instead of the ablative; but when we express the cause, the manner, or the instrument, we always introduce definite prepositions; hence it is translated in our language sometimes *in*, sometimes *by*, *with*, or *from*, and its meaning is rendered more special than in the original Latin. It is scarcely necessary to mention, however, that even in Latin it may also be preceded by prepositions, though it does not necessarily require them. We may say either *se gessit summa cum prudentia*, or *summâ prudentiâ*.

Some verbs govern the ablative as a single case, that is, with the apparent meaning of the accusative. These are chiefly neuter or deponent verbs. They seem to have originally been of the intransitive kind, and afterwards made to govern a noun in this slightly connected and least dependent of the cases. As *gaudere* "to rejoice," *gaudere felicitate alicujus* "to rejoice, the happiness of another being a concomitant event," which evidently would not be mentioned in this connection except as the cause of the joy. The verb *fruor*, in all probability, was originally passive in meaning as well as in form, and is capable of being translated "I am privileged," or "I am rendered happy;" *fruor vita*, "I am rendered happy in life," or "I enjoy life." *Potiri viribus*, "to be made rich by, or to possess, power."

The ablative is sometimes subordinate to an adjective, as *inops ratione*, "needy with respect to reason," translated "void of reason."

It is also governed by certain prepositions. Among these there are some that are also used in such a manner as to terminate the meaning without being followed by any noun; for example, *clam* "privately," and *palam* "openly." *Clam Cæsare* is "privately as to Cæsar," afterwards translated "without the knowledge of Cæsar." It is indeed true that even such prepositions as govern the accusative are sometimes used in the same manner as adverbs, that is, without any subjoined noun. This is the case with *juxta* and *contra*. But some difference may here be perceived; *juxta* and *contra* always refer to some specific object previously mentioned; *clam* and *palam* may be wholly general.

Some illustration of the ablative as compared with the accusative case may be derived from this consideration, that all the prepositions which denote that an action or motion terminates in the object signified by the governed noun, govern the accusative, as *ad* "to," *contra* "against," *in* "into;" they have thus a general analogy to active transitive verbs; while all those which denote that the object signified by the governed noun is the point at which motion commences, govern the ablative, as *a* and *ab* "from," *e* and *ex* "out of;" and, finally, those which denote fixed posture or condition are in their regimen distributed betwixt these two cases. *Ante* "before," *apud* "at," *secus* "along," *citra* "on this side of," and some others, govern the accusative; while *cum* "with," *pro* "for," *præ* "before," govern the ablative. But, though no uniform circumstance of syntax marks these last mentioned prepositions, some motive must have directed the persons by whom the language was modified to prefer in each instance one of the cases to the other. If we should suppose that they were derived from pre-existing verbs, the regimen would depend on the genus of each original verb. Prepositions governing the accusative are those which are most completely prepared for a transition of thought to the noun, and thus possess the most complete active energy. *Juxta*, for example, may be held equivalent in force to *jungentia* "joining," *apud* to the word "accompanying," *contra* to the word "opposing." Those which govern the ablative must have been considered as more passive, leading by a more leisurely transition to the subsequent noun. *Cum* might be considered as equivalent to "accompanied." The meanings of these prepositions may be expressed either in an active or a passive form. *Circum* may be analysed into "surrounding," and thus it governs the accusative. If it had originated from some such passive participle as "penetrated," it would have governed the ablative. This variety of syntax might sometimes be founded in etymology, and sometimes the result of arbitrary fancy.

The Greek language has no case corresponding to the ablative. The use of the genitive is in that language extended in such a manner as to include it. The Greek genitive seems to have a greater similarity to the Latin ablative than to the Latin genitive, as the ablative is the least dependent of the two, and possesses the most general application. In Latin it is in some instances governed by a noun; a circumstance which we have not before mentioned, as it takes place only in particular phrases, as *vir egregiâ sapientiâ*, or *vir egregiæ sapientiæ*. The Greek genitive is governed by prepositions like the Latin ablative; and the noun in the absolute state, which in Latin is put in the ablative, is in Greek in the genitive. In this latter language therefore we are left to infer from the connection, whether the meaning of the genitive case or one of those applications which in Latin are assigned to the ablative is attached to it in each particular instance. The only meaning proper to it is the general one of concomitance; and it may be either a concomitance with an object expressed by a noun, or, like the ablative, it may be concomitance with an idea expressed by an adjective, a preposition, or a verb.

In the French and English languages, the noun is subjected to very few variations corresponding to cases. We have the genitive in *s* with an apostrophe, which is sometimes called the possessive case. In the pronouns "I," "thou," "he," and their plurals, we have one variation, consisting in a case equivalent to the Latin accusative, and technically called the objective case; as "me," "thee," and "him." It is by means of this form, preceded by the prepositions "of" and "to," that the genitive and dative in Latin are translated; and by different other prepositions suited to each occasion, we express a variety of relations which in Latin are indiscriminately, and with less particular meaning, expressed by the ablative. In the French language, the nouns *je* and *tu* have in like manner *moi* and *toi* for their objective cases. *Moi* in that language is even used where the nominative would be used in English, as *c'est moi*, for "it is I." Hence some have described *moi* as a complete noun, being a nominative as well as an objective form. In the use of the English language, persons who have not been taught to adhere rigorously to grammatical rules, sometimes say "it is me," instead of "it is I." It is probable that this was orignally a legitimate use of the word, and that the establishment of a contrary rule has proceeded from a forced application of a Latin idiom. Even *moi* in French is not used as a nominative to a verb. The French do not say *moi parle*, or *moi fais*. It is only that sort of nominative which follows the substantive verb. (We do not here speak of that subsequence in mere arrangement which indicates interrogation, and depends on inversion, in which the nominative always follows the verb, as in *suis je;* and we do not think that any attentive reader would have taken such an exception against our views, though we had not stated this circumstance. Those who would have been so disposed may object to several others which the limits of this article do not allow us to defend against every slight exception. We here speak of that form of the noun which follows a substantive verb, after that verb has been introduced by its proper nominative.)

This application of the noun after the substantive verb is peculiar, and might with as great propriety have a peculiar form assigned to it as those which are expressed by cases. It has not an appropriate form, because it is of less frequent recurrence. In Latin, it is put in the nominative. In French it is put in the objective case, being treated as a state of the noun introduced (or governed) by the substantive verb. In English we now adopt the Latin idiom. But, while our language was unfixed, it certainly would have been equally natural to have followed a similar usage to that of the French.

## CHAP. V.

### *Of Adjectives.*

#### Sect. I. *The Nature of the Adjective.*

The impropriety of considering adjectives as intended to express our ideas of qualities, in contradistinction to our ideas of substances, has been already pointed out. The only objects known to us are qualities, and therefore this distinction has no foundation in nature. Qualities habitually conjoined, and forming definite assemblages, comprehend the whole of our concrete ideas, called ideas of substances. We have words to represent these assemblages, and words to represent single qualities. But this does not constitute the distinction betwixt substantives and adjectives. Both kinds of ideas are indiscriminately expressed by these two parts of speech. The adjective, like the substantive or noun, is the name of an object. The circumstance which constitutes its peculiarity is, that it also contains an intimation of the subordination of the idea expressed by it to the idea expressed by a noun in the same sentence. It has in fact the same application with the genitive case of the noun. Sometimes these two parts of speech may be shown to be synonymous. The words "Peter's," "Solomon's," "Cicero's," are by some called genitive cases, by others adjectives of possession. The words "Aristotelian" and "Ciceronian" are reckoned adjectives by all, and also such words as "Roman" and "Grecian." All of these equally contain the name of a person or country, with an intimation that it is to be connected with some other idea expressed by a noun in the sentence. We shall soon see the similarity of use betwixt these adjectives and such as discover less composition in their structure. We shall also see the cause of their apparent difference.

Some have asserted that the adjective by itself expresses no idea. This opinion has arisen from the circumstance, that it supposes some other idea expressed by a different word. But this is in reality an addition to its meaning. Every idea expressed by a substantive may also be expressed by an adjective, and *vice versa*. The idea expressed by "man" is also expressed by "manly;" and the idea expressed by the adjective "good" is also expressed by the substantive "goodness."

Perhaps it will be alleged that, when we use the adjective, we do not give a full representation of an object, but merely refer to it by mentioning a quality founded on some connection with it; that the words "Roman," "English," "Ciceronian," do not imply the full meaning of "Rome," "England," and "Cicero." In answer to this we must observe, that the greater part of words in a sentence are merely introduced for reference. Sometimes, where many words are used, and many objects of thought mentioned, those which are mentioned on their own account are comparatively few, the greater part of the words, including the nouns employed, being merely introduced for the sake of reference. "A Roman senator," and "a senator of Rome," mean exactly the same thing; therefore the ideas contained in the word "Rome" are also contained in the word "Roman."

Those whose reflections are in the habit of suggesting more subtile arguments may object, that the word "Rome" is a proper name, while "Roman" expresses a general quality. This, however, is the same objection in a different form. A part of the word "Roman" is a proper name. The generality of such adjectives arises from the variety of occasions on which proper names may be used. Their application in connection with other words thus becomes general, and the same thing may be said of any form of a noun that implies definite connection with other words. The adjectives "Roman," "Grecian," "French," "English," "Alexandrian," "Ciceronian," "Foxite," "Pittite," contain the names of individuals, but they become general from being applicable to many objects. A relationship to an individual becomes a generic quality.

There are, however, adjectives which express the possession of general qualities founded on no reference to a particular individual. These adjectives have less appearance of composition than those now mentioned, and are always shorter than the substantive nouns used to represent the qualities as separate objects. "Good," "bad," "hard," "soft," "light," "heavy," are shorter words than "goodness," "badness," "hardness," "softness," lightness," and "heaviness." It is from the aspect of words of this sort that grammarians have concluded that the adjective does not express a complete idea. They are never derived from the general name of the quality. It has been imagined that the ideas which such adjectives express are *essentially* general, that they have no corresponding objects possessed of an individual existence, and that, when substantive nouns, such as "goodness" and "badness," are derived from them, a forced effort is made to treat qualities in language as if they were substances. The just conclusion was not drawn, that substantives and adjectives, as mutually distinguished, are forms fitted for certain purposes in language, and not signs founded in any differences in the nature of the external objects signified.

The reason of the comparative brevity of words signifying general qualities, when in the form of adjectives, has been already hinted at. Individual instances of these qualities have no separate interest attached to them, and therefore the words expressing them contain an intimation of their annexation to some group. The names of groups, even though generic, are in the first instance so contrived as to be fitted to become the names of leading subjects of discourse; and ever after merely require a proper introduction to render them distinctive signs for individuals. It is at a more advanced period of human thought that single qualities become separate objects of attention, and then it is natural to create names for them by the composition of words previously in use.

The adjective, like the genitive case of the noun, is a word subordinate to a noun by which it is introduced. Sometimes it is employed to remind us of one of the ideas contained in the noun, as when a poet speaks of "fleecy clouds," "the azure sky," "and verdant foliage;" or when a historian, under impressions of indignation at any series of outrageous conduct, uses such expressions as "the infamous Robespierre."

The most usual effect of adjectives is, to reduce within a more limited range the application of a general term, by the addition of a circumstance which belongs only to a limited part of the genus which that term expresses. "A man" means one individual belonging to a certain class of beings. The words, "a good man," represent one belonging to a limited part of that class. An additional circumstance, attached by means of another adjective, would limit the meaning still more: and an accumulation of adjectives of this sort is capable of affording a combination of sufficiently limited occurrence for any purpose of distinctive description.

The subordination of the idea contained in the adjective to the noun with which it is coupled is in some instances less strict than in others. On some occasions, the ideas expressed by these two parts of speech might exchange places, without any material alteration in the meaning of the compound designation thus formed. "A written libel" is equivalent to "a libellous writing;" "a false assertion," to "an asserted falsehood." Although the purposes of connection in discourse require one of the ideas thus nearly equal in importance to be expressed by a substantive noun, the choice is left to the option of taste and convenience. In other instances in which they may be made to shift places, when the ideas which they express are the subject of a sentence, a corresponding change is required in the predicate, in order that the identity of the meaning may be preserved. The sentence, "a good man is a happy man," may be converted into "human goodness is conducive to human happiness."

It sometimes happens that the adjective expresses the idea which is intended to be the principal, and to which that expressed by the substantive noun is subordinate; as in the Latin phrase *ab urbe condita ad* (*urbem*) *liberatam*. In the translation of such phrases, the idea that is primary is expressed by a substantive noun, and the subordinate one by an adjective. The primary ideas introduced in this phrase, by the prepositions *ab* and *ad*, are the "building" and the "deliverance;" hence it is translated, "from the building to the deliverance of the city." Such idioms are to be considered as arbitrary inversions of the parts of speech, and do not invalidate the original subserviency of the adjective to the substantive noun, as well as of the genitive case to the noun by which it is introduced.

The adjective is very often employed as the predicate of a sentence. It then conveys, by the help of the substantive verb or copula, information of a connection betwixt the idea conveyed by it and the leading subject expressed by the nominative prefixed to this verb. As in the sentences, "Cicero was eloquent," and "Solon was wise."

### Sect. II. *The Etymology of Adjectives.*

Amidst the obscurity in which etymology is involved, it would be difficult to trace all adjectives to other parts of speech, and thus prove that none of them are original. But many of them which might be supposed from their appearance to be simple have been shown to be derived from verbs, and these verbs are expressive of motion.

Sometimes the adjectives thus derived signify qualities *produced* by particular motions. The adjective "left," in contradistinction to right, is from the verb *to leave*. The left hand is that which we leave or decline to use. "Tight" is *tied;* "full" is *filled;* "loud" is from *low'd*.

Sometimes the adjectives thus formed merely contain an *allusion* to the motions from which they are derived, as "odd" from *ow'd;* "straight" and "strict" from *stringere* to pull; "blind" from the old verb to "*blin*," or stop; "bold" from the verb to *build* or establish. "Brown" is from the verb to *bren* or *burn*. "Lewd" is the participle of the verb to *lew* or allure. "Profligate," an adjective used to depict a character destitute of all rectitude of principle, is derived from *profligare* to defeat.

Adjectives expressive of single qualities are sometimes derived from the names of habitual assemblages in which such qualities are conspicuous. The colour "yellow" is in Latin *flammeus* or *luteus*, because it is the colour of flame or of clay. The English word "yellow" is derived from the Saxon verb *geælgen* to burn or flame. *Viridis* in Latin, is from *virere*, to vegetate; and "*green*" in English from *grenian*, to grow.

From the analogies in etymology disclosed by the researches of Mr Tooke, it would appear that verbs expressive of human motion have been the roots from which almost all adjectives, as well as substantives, have been derived. This fact tends to illustrate the views given at the beginning of this article, on the principles which regulate the progress of the human mind in the formation of language.

Some adjectives contain an intentional allusion to the nouns and verbs from which they are derived, and something more is recognized in them than the current signs for annexed qualities. Such are the adjectives "*man*ly, *gentleman*like, *prince*ly, *nation*al, *provinc*ial, *world*ly, *earth*ly;" also "*earthy*, *hilly*, *stony*." The substantives are here fully expressed, and the terminating syllable denoting annexation is capable of being separated. Sometimes this last is merely a general sign of connection; at other times it signifies something more specific, and then the adjective is to be considered as formed by the combination of another adjective with a noun. Thus, "faithful" does not mean simply "connected with faith," but "full of faith," and, if analyzed into the genitive case, it would not be represented by the phrase "of faith," but "of fulness of faith." A "gentleman-like youth" is not "a youth of, or connected with, gentleman," but "of the resemblance, or likeness, of a gentleman." Where several synonymous adjective terminations exist, though all general in original meaning, different specific applications may be afterwards appropriated to them. Thus "earth-*en*" means made of earth, "earth-*y*," abounding with earth, "earth-*ly*" connected with the earth. In some examples we find both parts of the compound word restricted in their meaning. If *ly* means "like," the etymological meaning of the word "earthly" must be "similar to earth;" yet the word is employed solely to signify "connected with the system of of our earth," in contradistinction to the invisible world.

There seems to be a constant tendency amidst the fluctuations of language to coin new adjectives, by derivation from substantive nouns, for the sake of producing greater liveliness of expression. When such a word as "manly" is first used for describing an individual, the hearer more readily imagines to himself a "man," with all his suitable qualifications for the illustration of the quality named, than when such epithets as "bold" or "firm" are employed.

Some adjectives derived from *verbs* contain an equally palpable allusion to the parent words as those do which are derived from nouns, and thus bring more fully into view the motions or actions which they denote. The most remarkable adjectives of this sort are also called participles. They resemble other adjectives in every feature which has yet been mentioned; but many of them imply an additional characteristic, which will come into view when we treat of the verb. The participle expresses the meaning of the verb, together with its subordination to the idea expressed by a substantive noun. The words, "pining," "thriving," "dazzling," are as completely adjectives in meaning and use, as "weak," "strong," and "bright." Sometimes it contains the addition of a particular modification of connection. There is generally a difference betwixt the participle in *ans* or *ens* and that in *us* in Latin, and betwixt the participle in *ing* and that in *ed* in English.

The adjectives of some languages are subjected to variations corresponding with the cases, numbers, and genders of the substantive nouns to which they are attached. These are terminations. They are extraneous with regard to the meaning of the adjective, and are merely convenient marks for designating, in complicated sentences, the noun with which each adjective corresponds. They served, in the Greek and Latin languages, to obviate that ambiguity which must have been the consequence of the inversions of the order of words which the writers of these languages, especially the poets, perpetually practised. This circumstance, though merely accidental, has probably formed the ground on which grammarians have proceeded in calling the adjective a sort of noun. The declensions have given it a similarity of aspect to the substantive noun. The metaphysical reason for adhering to this nomenclature assigned by Mr Tooke, that both equally contain the name of an object, seems not to have occurred, and labours under the disadvantage of applying also to other parts of speech.

### Sect. III. *Degrees of Comparison.*

Many adjectives are subjected to variations, which indicate a comparison of the degree in which a quality is to be attached to different objects. There are adjectives which do not admit of this variation, because there are qualities which do not admit of degrees. Such are some of those which denote figure; as, "circular," "quadrangular," and "triangular." Adjectives subjected to degrees of comparison are those which express qualities which admit of being more or less intense. No language is without separate words to signify comparison. But an expression of that act is so frequently required, that it has been found convenient to combine the sign of it with the adjective, in the form of a termination.

Three degrees have been enumerated; the positive, the comparative, and the superlative. But the positive form is the simple state of the adjective, and should not be called a degree of comparison.

The comparative degree is formed, in Latin, by adding the syllables *ior* to the radical letters of the simple adjective; the superlative by adding the syllables *issimus;* as *mitis*, *mitior*, *mitissimus;* in English, by adding the syllables "er" and "est," as, "meek, meeker, meekest." When the euphony of our language does not admit of this mode of formation, the same thing is expressed by prefixing to the simple adjective the adverbs "more" and "most." Several grammarians have described the meaning of these degrees of comparison as consisting in this, that the comparative expresses a comparison betwixt two objects, i. e. a comparison of one with another one; while the superlative expresses a comparison with many, i. e. with the whole of a class. But we find that the comparative degree may be employed for comparing an object with many others as well as with one; as when we say, "He was *wiser* than all his teachers;" "Charity is *better* than a thousand sacrifices." The superlative degree, in its turn, may be used when only two objects are compared, as, "James is the *wisest* of the two." The difference betwixt these two sorts of expression, which should rather be called *forms* than *degrees* of comparison, is, that the comparative considers the subjects compared as belonging to different classes, while the superlative compares them as included in one. When we compare two men, if we oppose the one to the other, we use the comparative, and say "that he is *taller* than that other;" but when we place the two together to form a group, and point out the superior rank which one of them holds in this group, we say, "He is the *tallest* of the two."

In like manner a comparison in which more than two are concerned may be expressed either by the comparative or the superlative. The comparative is thus used when we say, "Greece was more polished than any other nation of antiquity." Here Greece is considered as not belonging to the class mentioned after the words "more polished." For this purpose these nations are designated by the term *other*. "Greece was none of those *other nations;* it was more polished than they." The same idea is expressed by the superlative when the word *other* is left out; "Greece was the most polished nation of antiquity." We here assign it the highest place in the class of objects among which we number it,—the nations of antiquity. A similar option is left in conveying such sentiments as the following: "Mr Fox spoke more forcibly than any other member of the House;" which may also be thus expressed, "Mr Fox spoke the most forcibly of all the members of the House."

The comparative is indeed sometimes used instead of the superlative where there are only two in a group; as when we say in Latin, *senior fratrum*, and in English, "the elder of the brothers;" "the wiser or the taller of the two." The frequency with which the comparative form of the adjective is employed in comparing only two, has misled some technical grammarians to state it as a principle, that this is the only proper form where no more than two objects are concerned, even although they should be represented as belonging to the same collection or class. But, though habit has admitted some instances of this phraseology, it is an error to form such a rule, and it is injudicious to check any tendency to use the superlative in its original application.

### Sect. IV. *Numerals.*

Numerals have the same relation to the substantive noun as adjectives, and therefore belong to this class of words. They express a modification or limitation of the idea conveyed by some substantive. Their peculiar object is, to denote the degree of frequency with which any sort of thought contained in a noun is repeated; that is, the frequency of the exemplification of a general idea.

In English, the singular number is sometimes merely distinguished from the plural by the want of the terminating *s*, as "the house" for the singular, and "the houses" for the plural. At other times the word "one," or the word "an," or "a," is prefixed. "An" and "a" have been called by grammarians indefinite articles, but in this there is no propriety. They merely signify unity, and this is expressed by them in the most definite manner. In the French language, they are always translated by *un*. They ought, therefore, to be called numeral adjectives. They cannot be prefixed to plural nouns, being peculiar to the singular, or the exhibition of an idea without repetition.

The words "some" and "several" are used as general plural adjectives. There are others implying the result of a general comparison with respect to number; as, "few" and "many." But these words do not describe the frequency of the repetition with precision, and for this purpose language is furnished with corresponding numeral adjectives. One added to one, forms a number which has the separate name "two:" one and one and one, or two and one, have the name "three:" one repeated once more, or a repetition of two, forms the number called "four." Our idea of number, as a separate subject of thought and of language, has no existence previous to our experience in numbering individuals. This gives rise to the observation of a general feature in the acts of the mind, called numbering; and hence the generalization of numbers. Words signifying a particular degree of repetition become applicable to all acts of the mind in which an idea is repeated with the same frequency.

The general words expressive of numbers are derived from the names of particular objects; though, perhaps, we can seldom succeed in tracing them. As the two sides of the body exhibit pairs of organs, two eyes, for example, and two hands, the word for "two" might arise from the most interesting of these pairs. Perhaps the numeral *tres*, "three," has been borrowed from the idea of vibration, and owes its etymology to the verb *tremo*, or some older verb of the same meaning. The two words are at least evidently akin. The words first used to express the succeeding numbers might be suggested by the first two or three, with the help of a sign intimating *reduplication*, as in "two," "four," and "eight," or *addition*, as in "five," "six," "seven," and "nine."

Numeration by *tens* has, with very few exceptions, taken place in every part of the world. This has been suggested by the numbering of the fingers, which form an assemblage familiar to us from our childhood. The word for "ten" would therefore be borrowed from the word signifying "hand," or "fingers." *Δεκα* in Greek, and *decem* in Latin, evidently spring from the same root with *δακτυλος* and *digitus*, a finger. The combinations of tens with one another, and the addition of the words for the different units, are prominent processes in the words employed among the ancients as well as the moderns for the higher numbers, and in the marks invented to express them compendiously in writing.

### Sect. V. *The Article.*

There is one adjective which, from some peculiarity, has been generally reckoned a separate part of speech, under the title of "the definite article." The English words *an* and *a* have been called indefinite articles, but their nature has been shown to be that of numeral adjectives. The words *ὁ*, *ἡ*, *το*, in Greek, *the* in English, *le* and *la* in French, and the corresponding words in other languages, have been called the definite articles; but they have every characteristic of the adjective. They have even corresponding inflexions in those languages in which adjectives are inflected. Their general meaning, and the purpose of the speaker in using them, are the same with those of the adjective. They represent an idea or quality subordinate to an object expressed by a substantive noun. This quality consists in a reference to some previous mention, or to some knowledge previously possessed of an object. A historian, after having named and described a variety of objects, speaks familiarly of them, by using their general names preceded by the adjective *the*, as, "the army," "the town," "the battle," "the siege," and "the truce."

Another use of it is, for attaching a speciality by means of a genitive case, or another adjective, or some of those phrases which we shall afterwards show to be equivalent; as, "*the* King of Prussia," "*the* governor of Malta," and also, "*the* French nation," "*the* Italian territory," "*the* Christian religion." Where no speciality is attached, it means, "known by former mention," or, "mutually understood betwixt the speaker and the hearer." Where it is followed by the genitive or another adjective, it means, "to be known or distinguished by this mark."

Some classes of objects are never mentioned without the use of this adjective, as, "*the* French," "*the* English." This phraseology has arisen from the habit of prefixing the words French and English to more general nouns, as, "the French or English people." We say, "the French are gay;" "the English love the pleasures of the table." We have, indeed, equivalent expressions without the article in the words, "Frenchmen," and "Englishmen."

The only circumstances which have led to the idea that the article was a distinct part of speech, seem to be the same which we have mentioned of the pronoun, viz. its brevity, and its frequency. It is a mistaken notion to consider it as possessing the power of distinguishing the application of a generic name to an individual, from the use of that name in a less definite acceptation. It has not this power in a greater degree than other adjectives. If we speak of "the man," we no more distinguish any individual, than when we say "a man," and not so much as when we say, "a wise man." It is only after an individual has already been distinguished that the adjective "the" characterises him, by referring to that description. It is of very general and familiar application; because any object may be mentioned as already known, or may be introduced with a view of being characterised by some special mark. Like every other adjective, it becomes fitted to particularise the intended object in proportion as it is used with skill and propriety.

Mr Tooke (vol. ii. p. 60.) derives "the" from the Saxon verb *the-an*, "to take," of which he supposes it to be the imperative. "The man," accordingly, means "take man;" and implies a direction to the hearer to select an individual from the rest of the class. This is its meaning, when the object is first introduced for the purpose of being described. When afterwards used for reference, it must mean "taken" or "selected."

Very nearly allied to the adjective "the" are the words "this" and "that," which have been denominated by grammarians adjective pronouns. "That" is considered by Mr Tooke as also derived from *the-an*, "to take;" and as, in fact, its past participle. In actual application "this" means "near," and "that" "at a distance." Another adjective, "yonder," signifies, "at a considerable distance," or on the other side of something referred to. "This" and "that" are either prefixed to nouns, as "this man," "that thing," or are used by themselves, as "this is good," "that is indifferent." In the last form of speech there is a subaudition of the noun; or the adjective may be considered as converted into a substantive noun, in the same manner as we have shown that many substantives are created. Like them, it expresses one quality, with a subaudition of the rest. An adjective used with the subaudition of a substantive, is very nearly akin to a substantive formed from an adjective by subaudition.

## CHAP. VI.

### *Of Verbs.*

### Sect. I. *The Nature of the Verb.*

The verb, as exhibited in elementary grammars, especially those of the Greek and Latin, is much more varied than any of the other parts of speech. Some ingenious attempts have been made to trace its complications, and to analyse its different forms. We find the offices performed by words called verbs to be various, and it would be satisfactory to discover the cause of the application of one common term to words so diversified.

The following are the queries which this subject suggests. Does the verb perform any office which is peculiar to itself, and is this common to every word which, in the present practice of grammarians, receives the appellation of a verb? Are there more points of coincidence than one in the application of the various forms of the verb? Is this coincidence in office strictly universal? Or are these different offices sometimes united in one verbal sign, while only one of them is performed by others? Are the offices performed by the respective words called verbs thus different among themselves? Are there any functions common to the verb with some other parts of speech, though more advantageously and more frequently performed by verbs than by these others? Does this circumstance render it advisable in any instance to retain the name of verb, even while the office performed by it is not peculiar? Or ought scientific accuracy to concur with convenience in leading us to alter in this instance the nomenclature of the parts of speech? These questions can only be answered by investigating the nature and use of every sort of word which, in the habitual language of grammarians, is denominated a verb, and making a comprehensive survey of their applications, in order to assign to all of them respectively their just rank in universal grammar. We must therefore suspend the discussion of the leading problem implied in the title of the present Section, and leave the reply to be gradually unfolded in the sequel of this Chapter.

One important form of the verb, the imperative, created by the earliest occasions for the invention of language, has already come under our notice. We have found imperatives to be the shortest of all words, and to consist of the roots from which the greater part of other words derive their origin. But, since we have considered all language as imperative, that subject does not form an appropriate commencement to our inquiries into the peculiar nature of the verb; and, in fact, it scarcely requires any additional observations to those already made on it. Many verbs from their meaning do not admit of direct imperatives, (to wit, those which do not signify the voluntary acts of mankind,) yet possess many forms in common with active verbs.

We shall first consider those forms of the verb which are subservient to affirmation, or, as it has been sometimes termed, *predication*, for the sake of including negations.

Sect. II. *Verbs as subservient to Assertion.*

Assertion or affirmation is the act peculiar to the verb, being never performed by any word which grammarians have referred to a different part of speech. That part of the verb by which it is most evidently and most frequently performed is called the *Indicative*. By means of it we convey information. This, though not the original object of language, is by far the most frequent application of it, especially in an improved state of society. It proceeds from that great characteristic of our species, the love of knowledge, implying an inclination to convey it to each other. It is by means of affirmation that language becomes the instrument of the most important improvements in human thought and in the character of society. An inquiry into its nature must therefore throw considerable light both on thought and on language.

In affirming, we connect different ideas together, and thus dictate an arrangement which we wish such ideas to assume in the mind of the person addressed. To this object a particular part of speech is devoted; but that part of speech often consists of a word which contains a sign of various other ideas. When we say "the man walks," the word "walks" contains the name of a particular motion, at the same time that it expresses a connection betwixt that motion and the object denoted by "the man." Mr Tooke considers the verb as containing a noun and something more; and he proposes it as a question worthy of the attention of philosophers, what is that circumstance which, when added to a noun or the name of an idea, makes it a verb? The answer to this, in so far as the indicative is concerned, is, that it contains a sign of asserted connection betwixt the object expressed by that noun or name, and some other object which is also mentioned in the sentence. But we have other signs of connection which are never considered as giving a word the nature of a verb. The genitive case implies a sign of connection betwixt the object expressed in that case and some other; the adjective performs a similar office; but there is a difference betwixt these signs of connection and that implied in the indicative of the verb.

The nature of these two sorts of signs, and the difference betwixt them, will be most clearly perceived by attending to the structure of those languages which enable us to resolve the indicative of every verb into its constituent parts, by affording distinct signs for each. In English "the man walks" may be resolved into this sentence, "the man is walking." The termination *ing* implies a connection similar to that expressed by the genitive case or by the adjective, while the word *is* gives the sentence the character of assertion, and fits it for conveying new information.

For the sake of possessing appropriate terms on this part of the subject, it will be convenient to borrow the technical language of logicians, who call a sentence a *proposition*, consisting of three parts, a *subject*, a *predicate*, and a *copula*. In such a sentence as we have now mentioned, each of these parts is expressed by a separate sign. "The man" is the subject, "walking" the predicate, and "is" the copula. The author of Grammar in Dr Rees's *Cyclopædia* maintains, that "is" does not express assertion, but connection. Connection, however, is often expressed by words of very different import: therefore that term is less appropriate to the copula than assertion.

Sect. III. *The Substantive Verb.*

The copula has been denominated the *Substantive Verb*, and it undergoes a variety of changes, called inflections, corresponding to the changes incident to other verbs.

The radical nature and common use of this verb is not, as Mr Harris supposes, to express existence, but to assert a connection betwixt one object and another. The author now mentioned has been unfortunate in his mode of describing the use of this verb. He pronounces it an undoubted axiom, that "an object must first be, before it can be any thing else;" an opinion in all points of view untenable. In the first place, it is not necessary that the subject spoken of should have an actual existence. We can speak of supposed as well as of existing objects. In the next place, an assertion that any object which has existence is something else, implies an absurdity.—What then is an assertion? Do we by means of it assert an object to be the same that is implied in the term used for an introductory designation? This is not the case; it would form an unmeaning truism; and the predicate is generally a different word from the subject. In this act we neither assert the subject to be the same, nor to be something else. The office of assertion consists in pointing out a relation betwixt the subject and some other idea. The word "gold" has one meaning, and the word "metal" has a different one. When we say "gold is a metal," we do not intend to say that the words "gold" and "metal" have the same meaning, but that the qualities expressed by the word "metal" are connected with the object called "gold." When we say "sugar is sweet," "wormwood is bitter," our intention is to produce in the mind of the person addressed a connection betwixt the ideas which have been previously attached to the word "sugar," and the further idea of "sweetness," and betwixt the ideas attached to "wormwood," and the idea of "bitterness." Sometimes nothing may be previously known concerning the subject of the proposition. We may speak of sugar and of wormwood to a person who has never heard of either. In that case the terms are only introduced as signs requiring the person addressed to attach to the one of them the idea of sweetness, and to the other that of bitterness, as contributing to those compound ideas of which he may afterwards consider the words as significant. The idea expressed in the subject must always be different from that expressed in the predicate. This is the case even though the expressions used would on a different occasion be synonymous. When the sentence "London is the capital of Britain," is uttered, if the hearer had any ideas about London, he is desired to connect with these the further circumstance of its being the capital of Britain: if he had no idea on the subject, except that London was a name written or pronounced in a certain manner, he is desired to connect this word as a name with those which form the predicate of the sentence. Sometimes, by a figure of speech, the same word is used for the subject and the predicate: for example, "Home is home." In the employment of this figure, however, it will be found that such a word as "home" in these two situations has a different set of ideas attached to it. The meaning of this sentence is, "Home, though often thought and spoken of with indifference, is, when made the subject of reflection, connected with feelings which interest and attach us."

The substantive verb differs from verbs of motion in being radically indicative in its character. Assertion is the cause of the contrivance of it. It does not originate in the imperative mode, any further than an imperative effort to command attention is implied in all language. The use of the substantive verb is, to direct the thought of a person to the connection of one idea, or one assemblage of ideas, with another, and thus to indicate congruities, incongruities, and relations of all kinds. The substantive verb is employed in the imperative, conformably with the usages of other verbs. We say, "be wise;" "be ready to do your duty;" but this imperative has always an awkwardness and a want of emphasis, compared to that of the active verb. An active imperative may be considered in such phrases as understood. It seems an absurdity to desire any person or thing *to be*, or even simply to be connected with another object, or to be endowed with a particular character. The imperative radically implied in such sentences is a command or solicitation to use such *exertions* as tend to the production of a certain state. *Sis probus* means *fac ut sis probus*, cause yourself to be good; act in such a manner as to support a worthy character.

All the other forms of this verb coincide in meaning and emphasis with the corresponding parts of other verbs.

The peculiar character of the indicative of the substantive verb is, to express in a separate word that general act of the mind which is common to all verbs in the indicative mood.

The *predicate* of a proposition may either be an adjective noun, as "Cicero was *eloquent*;" "Solomon was *wise*;" or a participle, as "the man is *walking*;" "the boy is *riding*." A substantive is applied with equal frequency to the same use, as "Isaac is *a philosopher*;" "George is *a king*;" "Alexander is *an emperor*." A connection betwixt the ideas expressed by these substantive nouns and those attached to the *subjects* of the propositions, is then asserted by means of this simple verb. The verb still merely serves the purpose of a copula. The noun becomes an adjective by its situation.

Dr Smith infers from the generality of the character of this verb that it must have been the result of much thought, and could have been formed only after refinement in metaphysical science had made considerable advancement. For this inference, however, there is not sufficient foundation. The acts exerted in all assertions have a character mutually similar, and are therefore called the same act; and nothing is more natural than to express the same act or similar acts by the same sign.

The early attempts of a child to speak are often made without the use of the substantive verb. He says, "That bread good," instead of "that bread *is* good." He possesses the ideas of bread and of goodness, and, by pronouncing the one in immediate succession to the other, he attempts to convey the impression which he has received of their mutual connection. The same mode of speaking may be supposed to take place among a people, whose mutual communications are few and crudely executed. But, as the juxta-position of nouns may also be applied to other uses, a separate sign is afterwards introduced for indicating assertion; and no depth of metaphysical knowledge is required to induce men to use the same sign on every similar occasion. Although some risk of error attends the intellectual exercise of retracing and analysing the progress of our mental operations, and hence metaphysical mistakes and difficulties have been handed down from age to age, no hesitation or impediment occurs in the employment of the faculties for the common purposes of speech. The human mind has always proceeded without embarrassment in contriving signs for its communications. The formation of a general word is equally easy with that of a significant general termination for shewing that words are applied to similar uses. A termination expresses some point of mutual resemblance in the application of words. The same thing is done by a separate word, and a separate word may be uttered with equal facility. The forms, in fact, which are common to all other verbs are exactly synonymous with the pure substantive verb. All other verbs consist of the signs of ideas, coupled, as we have observed, with the sign of adjection, and the sign of assertion; that is, the meaning of the participle with that of the copula.

### SECT. IV. *The Neuter Verb.*

SOME languages have verbs which contain the meaning of an adjective and the copula condensed in one word, and which have no further characteristic in the construction of sentences than these parts of speech when separately expressed. Perhaps this is not the case with every language, and there are probably none in which such verbs abound. In the Latin language, *rubere*, *virere*, *calere*, *frigere*, are instances. In English we have the verbs "to glow," "to blush;" but we for the most part express such ideas by using adjectives with the substantive verb in a separate state. The verbs now mentioned are called *neuter* verbs, in consequence of the absence of certain qualities which we shall find other verbs to possess.

### SECT. V. *Assertions made by Verbs of Motion or of Action.*

IT has been already observed that the first object which a man has in view, in using speech, is to excite to action. Were mankind destitute of vocal language, they would imitate the particular actions which they intend the person to whom they speak to perform. This is always done by persons who wish to converse while they are not acquainted with any common language. The case is necessarily the same with dumb persons. In tracing the origin of the words by which particular actions are represented, and the establishment of them as conventional signs, we find no general principle to guide us. The motive for using a particular sound is of so casual a nature, that its history is lost before it receives an established application. The want of written documents, and the total inattention to retrospective analysis, which exist in a state of society so rude, involve the origins of words in obscurity. Etymology can only trace a word from one application to another, and follow its variations through the different languages into which it has been adopted. Even this exercise is liable to deceptions which it is difficult to avoid. Yet it must be allowed that, when conducted with caution, it may prove extremely useful, by discovering analogical principles of transition, which elucidate this department of human art.

After men have learned to employ words for exciting one another to those actions by which reciprocal services are performed, the extent of the uses to which language may be applied must be soon more fully perceived. Men contrive to describe to each other various surrounding phenomena. Some of the most interesting of these consist of the actions of their fellow creatures.

The same sign by which we desire a person to perform a particular action, is naturally retained as a symbol of that action in describing any series of events of which it forms a part. After we have used the words "come," "go," "stand," "sit," "run," as imperatives, we spontaneously apply the same words, either in the same form, or with some slight addition or alteration, in affirmative sentences, such as "John stands," "John sits," or "John runs."

It has been already remarked that these indicative forms may be resolved into the copula with a participle, and are equivalent to "John is standing," "John is sitting," and "John is running." The connexions expressed by the participle are observed in the operations of the solitary mind before we are capable of using language, and form an extensive series of relations among the objects of our knowledge. But the earliest use that arises for connecting the significant words is the conveyance of information. On this account the copula and the participial sign are not originally separate, but condensed into one word with the name of the action specified. This early date of the condensed phrase is the cause of a comparative simplicity in the indicative form. It is prior in formation to the participle. We have occasion to say that a man "walks," sooner than we have occasion to use the compound designation "the man walking," as the subject of a different proposition. It follows *a fortiori* that the simple indicative is prior to that indicative which is formed by the participle and the copula. The division of it into these two parts might make the indicative appear more complicated in metaphysical analysis, and some might be disposed, on this view of the subject, to consider the usual indicative as a species of contraction. But this is not its character. The act which consists in the union of the meaning of these two signs is spontaneous, and of an early origin. On this account the indicative has even less complexity of form than the participle.

## Sect. VI. *The Active, Passive, and Middle Voices.*

It most frequently happens that, in describing an event, whether consisting of a voluntary human action or not, we have occasion to bring into view, by means of a noun, some object which has a conspicuous concern in it. The occasions on which no inclination to do this exists are but few, and the events which are described in a manner so simple are not of the most interesting kind. They occur in Latin in the use of such verbs as *ningit* and *pluit*, "it snows," "it rains." Each of these verbs, without any nominative, contains a full account of an event.

When we describe an action which has an intimate connection with some other objects, we generally have occasion to extend our description by the mention of the object or objects so situated. We may either mention one or more of the agents who perform the action, or an object affected by it. If the noun expressing this object is put in the nominative case, it becomes the leading subject of the sentence.

When the nominative is the name of an agent, the verb is said to be *active*. When it is the name of an object affected, it is said to be *passive*. (This mode of expression is somewhat illogical. It is the noun that becomes active in the one instance, and passive in the other. The difference of these two uses of the verb is, that they give these differences of character to the noun. We shall, however, adhere to the established nomenclature, as established by common usage, and possessing the advantage of a convenient briefness.) There are not in every language two separate forms of the verb for these two applications of it. In modern English, some verbs are used in the same form in an active and in a passive application. We can use the verb "cut" in any one of the three following ways: "They *cut* the tree;" "These tools *cut* smoothly;" "Fir *cuts* more easily than oak." We say, "Look at that person's face;" also "He *looks* well;" "Drink some wine;" and "This wine *drinks* pleasantly."

Some grammarians, impressed with the prominent distinction existing in the Latin language betwixt the verb in the active and the passive voice, would insist that "to drink" and "to cut" are essentially active, and therefore that the phrases "fir cuts easily" and "this wine drinks pleasantly" are ungrammatical. But we shall probably entertain a more enlarged as well as a more correct idea of the verb, by conceiving that those which we call active verbs are in their earliest application of no particular voice, though, from the agent generally appearing in the mind of the speaker more important than any object acted on, the active application of them is the most frequent. The original indicative of the verb thus points out a connection betwixt an object and an event, without specifying the nature of this connection. The circumstance of agency or any other may be safely left to the inferences formed by the understanding of the hearer.

In other instances, it is found convenient to contrive a mode of expressing by some slight alteration in the form of the verb the circumstance of being the object acted on. An expression of this sort, if found to harmonize with the genius of a language, may be afterwards universally adopted; and the original form of the verb will then be limited to the active application. In such languages, the distinction betwixt the active and passive voices will be most constant. This happens in the Latin language, and in the active and passive voices of the Greek. But, where the contrivances adopted for this purpose are in point of convenience less fortunate, they will be more varied and less strictly adhered to. Much will be left to urgent occasion or individual taste. Of this we have instances in the middle voice of the Greek verb, and in several phrases in the modern languages of Europe.

The French apply the verb in a passive acceptation, by introducing the same object as the nominative and the accusative to it, as *Le vin de Bourgoigne* SE BOIT *partout*, literally "the wine of Burgundy *drinks itself* every where." A verb thus used has been called a reciprocal verb, and it appears particularly appropriate when the same object is the agent and the object affected, as in the phrase "he prepares himself." Yet it is not necessarily limited to such occasions. *Le vin boit* does not mean "the wine performs the act of drinking," but "the wine has some connection with the act of drinking." The nature of that connection is here indicated by the accusative *se*. The phrase *le vin se boit* may be thus analysed, "The wine is concerned in drinking, by being the liquor which some one drinks." But we find that in English, when we say "the wine drinks pleasantly," the kind of connection betwixt the wine and the act of drinking is left to be inferred from the nature of the subject. This is of itself sufficiently prominent to prevent ambiguity, notwithstanding the incomparably greater frequency of the active application of that verb.

In other instances, a slight addition or a mere alteration is used for denoting the passive. In the Icelandic language, *æg elska* signifies "I love," *æg elskast* "I am loved." In Latin, we have *amo* for "I love," and *amor* for "I am loved." The expedients adopted in different languages will depend on the previous state of each. When a language already possesses a word expressive of suffering or being acted on, it will be natural to employ this, or some part of it, in union with the verb to denote the passive. It is not improbable that the letter *r*, which distinguishes the passive voice in Latin, is derived from *res* "a thing," or some previously existing word of similar import. The radical letters *am* signify "love;" *am-o* "I love," i. e. "I have some general connection with loving." *Am-o-r* "I am connected with loving as the *thing* or object loved." The letter *r* runs through all those forms of the passive voice which are produced by inflexion, with the exception of the second person plural.

The preterite tense of the passive verb in Latin is made up of a compound phrase, consisting of the participle with the substantive verb. The participle employed is derived from the past tense. *Amatus* is most probably a contraction for *amavit us*, and derived from *amavit*. The past tense is thus converted into a part of speech resembling the adjective; and the effect of the past is exhibited as a quality which is to be connected or adjectived to some other idea expressed in the form of a substantive noun. The introduction of the copula forms an indicative or asserting sentence. This shows that assertion was not early appropriated to that particular sort of connection betwixt actions and other objects.

The best passive form of the verb which the English language possesses is in the preterite tense, and yet it is of an equally compound nature with this part of the Latin passive. We adopt the sign of past action in the form of an adjectived quality, and complete our assertion by inserting the copula. "Destroyed" is the past tense of the verb "destroy." "The enemy's troops *destroyed* the city" expresses the active voice. "The city is *destroyed*" expresses the passive.

We have no good contrivance for a passive voice in the present indicative. *Domus ædificatur* cannot be literally translated into our language. When we say "The house is built," we assert the completion of an action. The nearest approach which we make to it in respect to tense is by the phrase "the house is building;" but here we confound the voices, at least we employ a word which in respect of voice is general, as the participle in *ing* is most commonly used in the active voice. Some of our southern neighbours choose to express their meaning by the phrase "the house is being built," which is no farther appropriate to the present tense than as the same combination never happens to be used for the past. It labours under the disadvantage of an awkward verbosity, which prevents it from being generally adopted, or sanctioned by the authority of persons of taste. Another effort has sometimes been made to supply this want by prefixing the letter *a* to the present participle, and thus converting it into a passive present, as "the house is *a*-building," but this has not succeeded in meeting with a permanent adoption. A strictly appropriate phrase has not been found absolutely necessary, because a slight alteration in the form of our sentence enables us to dispense entirely with the passive form of the verb. We can say "the building of the house goes forward," or "the work people are engaged in the building of the house." No inconvenience is experienced in expressing our meaning; it is confined to our attempts to translate Latin sentences literally into English.

In the French language the passive voice is much less frequently used than in English. That language has a resource which few others possess, for introducing the object acted on after the active verb without the mention of any particular agent, as it has a nominative of a very general application, *on* or *l'on*, signifying merely "some being or beings real or imaginable." This is prefixed to the active form of the verb, and the object acted on is conveniently made to follow in the accusative (or objective) case. *On le dit*, "some being or beings say so," is translated, with propriety "it is said."

Our language is equally defective in a passive voice for the future as for the present. If the sentence *domus ædificabitur* is translated by the phrases "the house will be built," or "the house will be building," or "a-building," or "will be being built," we shall find these forms to labour under the same disadvantages with the attempts already mentioned to give a translation of the words "*domus ædificatur.*" Yet we experience equally little inconvenience in this as in the former instance, because a moderate skill in varying the turn of our sentence enables us to convey our meaning clearly without the use of a passive voice.

A neuter voice might be formed, consisting of a separate word to signify that an action takes place, in a manner similar to the words *ningit* and *pluit*. We might have a single word for "there is," or "there was a walking;" in French, *l'on se promene*. In Latin, the passive voice is sometimes used in this neutral or impersonal manner. *Ambulatur* is not passive in any thing else than in form. It means "the act of walking goes on;" *ambulatur ab illo*, "the act of walking is performed by him," for "he walks."

### Sect. VII. *Regimen of the Active Verb.*

Some actions are of such a nature that the object affected by them is always interesting, and, in the earliest use of language, such actions are never related without immediate mention of an object thus affected. It also happens on such ocasions, that the manner in which the object is affected is evident from the nature of the action. Of this nature are the actions expressed by the verbs "to make," "to build," "to cut," "to strike," "to kill." Such verbs in the Latin language generally govern the accusative case, intimating the most rapid transition from the idea conveyed in the governing verb to that conveyed in the noun. The noun governed may, in consequence of its own regimen, be rendered introductory to further additions both to the form and meaning of a sentence. The verb thus becomes a hinge on which the greater part of the meaning of a sentence turns. The large proportion of verbs which govern nouns in this manner has conferred a conspicuous rank on this part of speech. It is in this respect more powerful than the adjective. Even when adjectives are used as predicates in affirmation, the meaning which they introduce generally terminates in themselves, or leads to subordinate ideas only through the medium of prepositions. We say "this man is good," "that man is just;" also, "this man is good at heart," "that man is just in all his conduct." It is seldom that adjectives in Latin can be admitted to govern the accusative; and even the phrases in which this might appear to take place, such as *Os humerosque similis*, are commonly explained by the subaudition of the preposition *quoad*. These differences betwixt the active verb and the other parts of speech have had a secret influence in leading grammarians to attach great importance to the verb. Its full power seems to reside in this form of it. Verbs of other kinds have appeared to be exceptions, or words to which convenience has assigned a verbal form, though they are not originally entitled to it.

The governing powers of the active verb are retained by the active participle and the infinitive mood. This act seems to have led grammarians to consider these forms of words as parts of the verb properly so called. The participle is distinguished from the adjective by regimen alone. Hence those grammarians who call participles real adjectives have always been most fully satisfied with the appellation when applied to the participles of verbs destitute of regimen, such as "thriving," "charming," "surprising," words which are in all respects used as adjectives, though participles in etymology and in form.

The infinitive mood has the same similarity to the substantive noun as the participle has to the adjective. It may become a nominative to a verb, as "*to enjoy* is to obey;" or an accusative, as "men generally wish to *live* long;" but, when introductory to other words, it has a more powerful and ready regimen than the noun. In Latin, it like the verb governs the accusative, and not exclusively the genitive, like the noun. We shall afterwards consider more particularly the participle and the infinitive mood. At present we have merely accounted for the fact, that grammarians have reckoned them real parts of the verb.

It must always have been obvious that this office of the active verb is not common to all verbs, and therefore is not characteristic of this part of speech; and, if the participle and the infinitive mood are to be reckoned parts of the verb, the problem still remains unsolved, what is the true characteristic of the verb? Mr Tooke intimated that he was prepared with some doctrine which appeared to himself satisfactory as a description of the verb, including its infinitive mood. Every philologist must regret that this acute writer did not communicate his views more fully to the world. On this part of the subject, it is possible that they may have been both well founded and original. We are certain that they would have been at least worthy of attention. They appear to have been valuable in his own eyes; they would have been exhibited in a forcible manner if he had chosen to publish them, and might have led the way to a more satisfactory account of the subject. But, as no explanation of this sort occurs on our own most matured reflections, we naturally suspect (however presumptuous the declaration may appear,) that his theory would have either turned out eventually inconsistent with some of the opinions which he has published, or would have been in itself unsatisfactory.

A precise answer to the question in the form now proposed is not of great importance. We have pointed out assertion as one office which is performed by verbs alone. We have pointed out the quality of an active regimen, as belonging to an extensive department of verbs, and have shown that this quality is possessed by parts of speech closely allied to the verb in etymology, and generally numbered among its parts, though not possessing an asserting power. We have shown in what words assertion and a transitive regimen are separate, and in what they are combined. Assertion is separate in the indicative mood of substantive and neuter verbs; the transitive regimen, in the infinitive mood and active participle of active verbs. We have endeavoured to investigate the connection betwixt these parts of speech and the indicative of the verb. In so far as their character is inconstant or complicated, we have stated the causes of these characteristics, and the shades of variation by which they are distinguished. We have shown in what respects the intermediate kinds of words partake of the nature of one part of speech, and in what respects they partake of the nature of another. If the particulars on these subjects are impressed on our minds, our theories will be exempt from ambiguity or confusion.

### Sect. VIII. *Intransitive Active Verbs.*

Neuter verbs have no such regimen as has been now described. Hence some have assumed this as a mark of distinction betwixt them and active verbs. It did not however escape observation, that some verbs which do not govern any noun signify action, and that therefore the term *neuter*, as implying the absence of active power, did not apply to them. For this reason these have been retained in the list of active verbs, but distinguished from verbs of regimen by the additional epithet *intransitive*. Their peculiar character has been generally represented as arising from this peculiarity in the nature of the actions signified, that they do not affect any ulterior object. But this is not true in point of fact. The transitive or intransitive nature of verbs of action depends solely on the occasions of mankind in making use of language. Transitive verbs are those which express actions when we have occasion instantly to mention an object acted on. Intransitive verbs describe actions when we are satisfied with stating the connection betwixt the action and the agent. Verbs which admit of no direct regimen, and therefore are termed intransitive, may introduce other ideas, expressed by nouns, through the medium of prepositions. The verb "to strike" is *transitive*, while the verb "to walk" is called *intransitive*; and yet it is evident that in the act of walking one or more objects are acted on as much as in the act of striking. Only it happens that when we speak of striking, it is generally of importance to point out the object that is struck; but, when we speak of walking, our attention is chiefly directed to the act as connected with the agent. In walking, however, a man walks *upon* some object which supports him; he walks *from* some place, and *to* some other. Each of the phrases "I strike my horse," and "I walk upon the ground," expresses, in a manner equally explicit, a particular act, together with an object affected. The intervention of a preposition in the one case, and the absence of one in the other, imply no difference in the energy of the act related, but only the different degrees of interest excited in the connection of it with the object affected. It might naturally be expected, from the numerous and varied occasions which we have for the relation of events, that, even in describing the same sort of action, we should sometimes have a motive for mentioning an object affected, and sometimes not. For this reason some verbs differ from each other only in their transitive or intransitive application, of which we have already given an instance in the difference betwixt the verbs "to speak" and "to say." In other instances the same verb is used either transitively or intransitively. We may say at one time, "a miller grinds corn;" in this sentence, corn is the object affected by the act; at another time we may speak of the same act as characteristic of the situation and employment of an individual; as in the sentence, "two women were grinding at the mill, the one was taken and the other left." Here no occasion arises for mentioning any object on which the act of grinding is exerted. These however are not two different meanings given to the verb. In both cases it is used in its full meaning, that of describing a species of action. Whether we choose to introduce or omit the name of the thing acted on, depends on the design which we have in forming our discourse. It may or may not be of use to add this circumstance to the description. It makes no more difference in the original meaning of the word, than the introduction of a second sentence in elucidation of the subject would affect the meaning of the words in the sentence first employed.

Sometimes verbs which are originally intransitive, and evidently not intended to have nouns subjoined to them, except through the medium of prepositions, are afterwards applied as active verbs governing the accusative, in consequence of the familiarity which the expression of particular kinds of connection acquires from habit. The verb "escape" originally required the preposition "from" to express a certain sort of connection betwixt the act and other objects. Yet we not only say "a prisoner escaped from prison," but, speaking of our own memory, we may say that "names and dates escape us." *Fugere*, in Latin, is a verb of the same kind, and the corresponding phrase *me fugit* is used in that language. *Me latet* is of a similar nature. *Ardere* is transitive, or perhaps ought rather to be called neuter, yet it is made to govern the accusative: *Formosum pastor Corydon* ARDEBAT *Alexin*.

In some instances an active verb, which we are in the habit of connecting with nouns by means of prepositions, is used to form a transitive verb, by being compounded with a preposition governing the accusative, and evidently derives its transitive power from the preposition. Such a verb, like others which govern the same case, may be used in the passive voice. In Latin we have such words as *initur*, "it is entered on." In English the same thing takes place, though the two words continue separate. The phrase thus formed is treated like a compound word, and made to pass through variations similar to those to which entire words are subjected. Such are the phrases "to laugh at," and "to trifle with:" the preposition and the verb coalesce to form a sort of compound verb, which is used passively in the phrases "to be laughed at," and "to be trifled with." This species of coalescence of words into phrases, subjected to a peculiar inflection, even takes place in instances in which an active verb governs a noun in the accusative, and then leads to another by means of a preposition: as in the phrase "to make a fool of;" for we do not say in the passive "a fool was made of him," but "he was made a fool of." We have many analogous examples; as, "to be made game of," "to be evil spoken of," "to be taken notice of," "to be taken care of." Some even say, "to be paid attention to." This last expression is inelegant, because it shews an unsuccessful grasping at a variety of accommodation.

On the *diversity* of regimen of verbs, see our account of the cases of the noun. The subjects are inseparably connected, and under that head such observations as appeared necessary have been delivered.

### SECT. IX. *Persons and Numbers.*

VERY little remark is required on the meaning attached to the *Persons* and *Numbers* of the verb. But the nature of their connection with this part of speech may be illustrated by their etymology.

In those languages in which verbs receive separate terminations for distinguishing the first, second, and the third persons, such terminations are pronouns, and are equally complete as if they were separate words. The terminations *o* in *amo* was probably derived from *ego*, the *s* in *amas* from συ, the *t* in *amat* from αυτος, the *amus* in *amamus* from ημεις. These terminations shew traces of being the same pronouns slightly modified. Some philologists who find themselves at one time dazzled by Mr Tooke's plausible etymologies, are at another startled on finding instances to which his principles cannot be applied, and on this ground rashly become disposed to condemn the whole as fanciful. A person under these impressions might perhaps stop us short in the inflections of *amo*, with asking the etymology of the terminations *-atis* and *-ant* in the second and third person plural. *Atis* affords no vestige of the Greek ὑμεις, nor *-ant* of αυτοι. It would be too bold to maintain that they are derived from words so dissimilar to themselves, unless we were able historically to point out the intermediate steps of their transmutation. But difficulties of etymology do not in the least invalidate the general position, that such terminations are real pronouns. *Atis* and *ant* have exactly the same meaning with ὑμεις and αυτοι. Whether they were derived from words subsequently forgotten, or were applied in the first instance as terminations, they are to be considered as complete signs, equally significant with separate words, and differing from the latter only in being placed not before but after the radical letters of the particular verb, and written in closer connection with them. The resemblance of some of the terminations to the separate pronouns is in fact happily adapted to corroborate the identity of their signification; but though no such resemblance existed, just reflection would lead to the same conclusion.

In speaking of the personal pronouns, we observed that they have all the characters of nouns, and that their whole peculiarity consists in their frequent use, which has occasioned a convenient brevity in their form. It is to the same cause that they owe the further distinction of being attached to many important words in the shape of terminations. In Greek and Latin we find them attached to the verb. In the Hebrew and Arabic they are attached in the same manner to nouns. *Ism*, the Arabic word for "a name," receives the terminations *-i*, *-ek*, and *-ou* for signifying "my name," "thy name," and "his name."

The inflections of the English verb possess a character somewhat different from those used in the Latin language. They do not supply the place of nominatives, but are used along with them. We say "I love," "thou lovest," "he loveth" or "loves." We never say "love" for "I love," "lovest" for "thou lovest," nor "loveth" and "loves" for "he loveth" and "he loves." The terminations in English therefore are not complete pronouns, as in Latin; they are only accompanying signs, denoting that a particular sort of word is the nominative to the verb. They might be represented as redundancies, but they are not destitute of meaning and utility. Though not absolutely necessary to guard us against mistake, they contribute to precision. They enable us to expatiate on a variety of circumstances in connection with the object exhibited in the nominative case, before we introduce the verb; and then the form of the verb shows its connection with the person mentioned in the nominative. But as the terminations in English are not so essential as in Latin, they are fewer and less varied. The first person singular, and all the three persons plural, consist of the simple verb with the pronoun prefixed. "I love, we love, ye love, they love." For this, among other reasons, our language admits of less inversion in the order of the words.

The same observations apply to the *Numbers* as to the persons of the verb. The use of them in the imperative mood is conducted in the same manner as in the indicative. In the passive voice they follow similar analogies as in the active.

### SECT. X. *Tenses.*

A REFERENCE to time is inseparably connected with the narration of events, and therefore many parts of the verb are so contrived as to indicate in their structure a connection with some portion of time, in contradistinction to another. The point of reference naturally first assumed is the instant in which the sentence itself is uttered. Hence the first general division of tenses is into present, past, and future. Points of reference may also be selected from the past and the future, and expeditious methods, suited to our various occasions, adopted for expressing relative precedence or subsequence.

References to the division of time into definite portions, as hours, days, weeks, months, and years, are always made by means of nouns contrived for the purpose.

1. *Tense of the Imperative.*

Before proceeding to the tenses of the indicative, which are the most important and precise, that of the imperative claims some attention. The form most frequently used in Latin and in English has been called the present imperative; but a little attention will shew that imperatives are essentially future. The act to be performed must be subsequent in time to the command. In many instances they may be separated by a considerable interval, without any alteration in the form of the verb employed; as when we say, "come to this place to morrow." Though sensible of this circumstance, grammarians seem not to have been aware of its importance in demonstrating the tense proper to this form of the verb. Perhaps a vague idea existed that the time of the *giving of the command* ought to fix its tense, but this is obviated by the slightest reflection on the subject, as the act performed by the speaker in every sort of sentence is present. Perhaps the *immediate* nature of the *influence* intended to be produced by the imperative on the mind of the person addressed has, though future, been considered as sufficient to entitle it to the appellation of present. But this influence is in no respect a proper foundation for a distinction of tense. All language is intended to produce an immediate effect on the mind. It is therefore solely with the time of the action or event specified in the verb that philosophical grammar is concerned in tracing the different tenses. The future in English is sometimes used instead of the imperative, as "thou shalt not kill;" "thou shalt not steal." Perhaps grammarians who delight in distinctions would perceive in this phraseology, as compared to the common English imperative, some analogy to the varieties of imperatives in the Greek language, and would denominate the sentences last mentioned future imperatives, in contradistinction to the common form called the present. But in the meaning of the sentences the tense is equally future in both.

The Greek language has various imperatives, which grammarians arrange along with the different tenses, and distinguish by the names of the present, the aorist, and even the preterite imperatives. But this diversity of form can produce no corresponding diversity of tense, unless this should consist in discriminations in the portions of future time to which the commands refer. We may order a person to begin an action at a particular time; or we may order him to be engaged in some occupation which is supposed to be previously begun; or we may order him to have an action completed. But, with reference to the primary division of tenses into past, present, and future, the imperative must be regarded as essentially future.

2. *The Aorist and Present Indicative.*

Mr Tooke has remarked that the part of the verb called the present indicative is a simple or general indicative, and that no tense is implied in it. When we say "the sun rises in summer much earlier than in winter," we assert a fact applicable to past, present, and future. Of the same nature are mathematical theorems and all general propositions. This form of the verb might therefore with respect to tense receive the appellation of a universal aorist. This indeed is the form of the verb used for describing present transactions. The idea of present time is on such occasions attached to the sentence, in consequence of an inference drawn from the nature of the subject.

In some languages it is elegantly used to describe a long portion of past time extending to the present: as in French *Je suis ici trois ans*, and in Latin *Tres annos hic adsum*. But it is also used in describing events which have been completed at a time past, as, "Yesterday, when walking along, whom *do* I meet but my old kinsman:" "I am glad, *says* he, to find you looking so well." Grammarians, never doubting that such indications are essentially of the present tense, have supposed that in such sentences the past is, for the sake of vivid representation, described by a figure of speech as present. The facts now stated shew that such explanations are unnecessary; and if they are in any degree just, or adapted to the conceptions which we attach to this form of the verb, the consideration that this indicative is not restricted to any tense will account for the facility with which we reconcile our minds to a figure of speech, which would otherwise appear a distortion.

We sometimes also use this general indicative in describing future events, and their futurity is pointed out by some other word in the sentence, or by the evident import of the whole. "Next Tuesday *is* the first of April," is a sentence equally proper with "next Tuesday will be the first of April." And we say, without any dread of being accused of vicious diction, "To-morrow he *begins* his journey."

It would be possible for men to convey their meaning on all occasions by indicatives, without any distinction of tenses. The mention of other circumstances might serve to prevent the hearer from confounding the past, the present, and the future. But a sign of general application, consisting either of a separate word, a termination, or a systematic variation of the verb, is an important convenience.

We are not altogether destitute of resources for marking with precision the present tense. Every language possesses separate words for the purpose, such as *now* in English, and the corresponding words in other languages. It happens that, in our language, without the use of such additions, we indicate present time, by employing the substantive verb with the participle instead of the usual indicative. "He writes" is the indicative without tense. "He is writing" is the present indicative. When we say "He writes a good hand," or "He writes to his relations every month," we restrict our meaning to no particular time. But, when we say "he is writing," we describe a present transaction. This distinction is entirely conventional. The original meaning of this combination of words implies nothing to distinguish it from the simple indicative, as the verb "is," and the termination "ing," are, with respect to tense, equally general.

3. *The Preterite Imperfect and Perfect.*

The preterite tenses are of great importance in language; and all tenses by which knowledge is communicated imply a reference to past time. To the past we owe our information. Our efficient communications of knowledge consist in references to the past. Though the present exhibits nature as immediately perceived by the senses, which are the inlets of knowledge, it is by means of the past that we are enabled to form a judgment concerning the objects perceived. On our past experience depend all our judgments and expectations regarding the future. If language consisted essentially in assertion, the past tense would be the original form of the verb. Grammarians state this to be the fact in the ancient Hebrew. In that language the preterite is in all verbs simple and uniform, consisting of two syllables, which are formed of three consonants, with two interposed vowel sounds. The differences of the consonants distinguish the verbs from one another, while the vowel sounds are the same in all. Such are the verbs בקר (*pakad*) *visitavit* כתן (*nathan*) *dedit*. The verb in this form is considered as furnishing roots from which all other words are derived. But those who have concluded, from the concurrence of all the facts in other languages, that the imperative is the original form of the verb, will find no necessity for adopting a different opinion of the formation of that ancient language. The imperative is in it equally simple with the preterite, generally consisting of the same consonants, varied most probably by a variation of the vowels. It has, therefore, on this principle, an equal claim to be considered as the root. In some instances it is shorter: in the verb כתן (*nathan*) it is תן (*then*.) Verbs thus formed are on that account denominated irregular. But the fact, in such instances of the greater brevity of the imperative, shews that the Hebrew in this respect does not differ from other languages. The simplicity and regularity of the preterite, however, in Hebrew, may be considered as a consequence of the important rank which that tense holds in the most prevalent application of language.

In English, the past tense is formed by a variation on the root of the verb as used for the imperative. This most commonly consists of the addition of the termination "ed." Others are formed by variations of the vowels; as "struck" for the preterite of "strike," "wore" of "wear," "bore" of "bear", "drove" of "drive." "I walk," and "I drive," are assertions in the aoristic or present indicative; "I walked," and "I drove," are in the past. This tense implies that an action was begun, and was continued at some past period. It is called the *imperfect*, because no definite relation to the present state of the event is implied in it, and room is left for supposing that the action may be still continued.

When we mean to assert that an action is accomplished, we introduce before the expression of past tense the auxiliary verb "to have" in the present or general indicative. "I have walked," signifies, "I am in possession of the complete act." "I have (by my own exertions) assured myself of its completion."

Some English verbs have two variations of the radical word for expressing past time, "strive," has "strove," and "striven;" "weave," "wove," and "woven;" "break," "broke," and broken;" "do," "did," and "done." The completed act is expressed by the last of these forms, the words "striven," "woven," "broken," and "done." Mr Tooke considers this contrivance as a redundancy, because one word for past time is sufficient for every purpose. In verbs which have the preterite in "ed," the same word is used for the simple description of an event in a train of progress at some past period, and for being conjoined with the verb "have," to signify that the act is completed. The insertion of that verb is sufficient for marking the distinction. "He walked," and "he has walked," are equally distinct from one another as "he did," and "he has done." In some verbs in which the preterite is formed by a change of the vowel, the same simplicity is observed: "struck" is used for both these varieties in the expression of past events.

That form of the past tense which is conjoined with the verb "to have," some grammarians consider as originally and properly the passive participle. In this sentence, "I have driven a nail into the wall," they consider the verb "have" as governing the noun "nail" in the accusative, and "driven" as the passive participle agreeing with the noun. In this form of the past tense, the same word is always used as for the passive participle. Therefore the sentence is considered as signifying in etymological analysis, "I have a nail (which is) driven into the wall," transferred by use and common consent to signify that the action is performed by the individual mentioned in the nominative. This theory receives apparent support from the structure of some phrases in the Italian language, which show that the passive participle is really the word employed, as its inflections are varied and made to agree with the noun in gender and number. Such is the phrase *Ho aperte le vostre lettere*; "I have opened your letter." This analysis of such phrases would have great probability, if the facts uniformly corresponded with it. But it is not a constant rule. It is often left even in the Italian to the option of the speaker. We may say *Ho aperto* or *aperte le vostre lettere*, *e veduto* or *veduta ivi la vostra cortesia*. The French say *J'ai donné*, not *donnée occasion*. *Il a tué*, not *tués*, *ses ennemis*. *Donnè* and *tué* therefore merely signify a past action, and, like any other part of the verb, introduce or govern the subsequent noun. They cannot be considered as agreeing with it like a passive participle. If it is convenient to have a separate name for that part of the verb, it may with sufficient propriety be called a *Preterite Gerund*. The peculiarity of its nature will appear in the most convincing light, when we turn our attention to neuter and intransitive verbs, which, having no passive voice, cannot be said to have a passive participle. When we say "he has gone," "I have come," the words "gone" and "come" cannot be past participles agreeing with nouns, as no nouns are introduced after them. There is no sufficient reason why the introduction of a noun should alter the nature of the word. In the phrase "I have struck," the word "struck" signifies action, and, as a part of the active verb, it may govern the accusative case with as much propriety as any other part of it. When we say "I struck my enemy," and "I have struck my enemy," the word "struck" is in both instances equally active in its meaning. There are certain occasions in which the past participle in the French language is used to agree with the governed noun; but these are altogether peculiar, and cannot give any room for supposing that this is the original construction of this form of the preterite, afterwards transferred to an active meaning; for it only takes place when the substantive noun has been previously introduced, and then referred to by means of the relative *que*. The French say *Il a* TUÉ *plusieurs hommes*; but, *Les hommes qu'il a* TUÉS. This was a subsequent arrangement, admitted after a long discussion of the French academy. There is some affinity betwixt this gerund and the past participle, though their syntax is not identical. Both signify an event completed. The participle is only the past tense, transferred to the adjective or participial application, by which a past action is treated as a quality introduced for describing an object. Its active application is of prior date, and is in constant use.

It is not necessary to treat particularly of the other forms of past tenses, as they are regulated by the same principles, whether they are formed of combinations of words, as in the modern languages of Europe, or combinations of syllables, as in the ancient languages. Some observations connected with the general subject of their varieties will be suggested by certain forms of the subjunctive mood.

### 4. *The Future.*

The signification of the future tense requires no illustration. The remarks which we have to make on this subject will therefore be confined to its etymology. Our conceptions of future events are mere deductions from known arrangements in the past or present, tending to modify their character. Hence all the contrivances for expressing futurity, that can be traced to their origin, are founded on the connection in which the future stands to the past and the present as an effect to a cause. They are derived from verbs signifying resolution, obligation, or other preparatory circumstances, and, with respect to etymology, are equivalent to the words employed in such English expressions as "I intend to go," "I must go," "I am likely to go," "I prepare to go."

Mr Tooke ingeniously derives the Latin future in *bo* from βȣλειν "to will" or "to be resolved." In *ibo*, for example, *i* signifies "go," *b* (from βȣλ) "will," and *o* (from εγω) "I." *Amabo* and *docebo* are formed by annexing the same letters to *ama* "love," and *doce* "teach.". The future in *am* he considers as an adaptation of the radical letters of *amare*, "to love." *Legam* is thus equivalent to *legere amo*, *audiam* to *audire amo.* By those who indulge a general scepticism in etymology, or who have other systems to support, these derivations may be thought improbable, and abundant opportunities are afforded of taking refuge in the obscurity of old derivations. It may be said, if *b* means βȣλω in *amabo*, what is meant by the *b* in *amabam?* Such objections can have no further effect, than to throw discredit on instances of etymology that are somewhat obscure. Let us therefore attend to some which are of recent formation, and which, as the successive steps of their change are easily traced, are superior to all objection. If general principles of analogy are there disclosed, by which the abbreviating contrivances of language have been conducted, the uncertainty of some antique instances is not to be much regretted. The former will also assist us to judge of the degree of probability to be attached to some etymologies otherwise uncertain.

In Italian, the future tense has undoubted marks of a derivation from the verb *avere* "to have." *Partiro* "I shall depart," is evidently derived from *partireho* "I have to depart." This is evinced by the identity of the terminations of the future with those of that verb in the present in all its persons and both numbers. *Ho*, *hai*, *ha*; *havemo*, *avete*, *hanno*: *Partir-o*, *partir-ai*, *partir-a*; *partir-emo*, *partir-ete*, *partir-anno*.

The French future is as evidently derived from the present of the verb *avoir.* In the verb *parler* it is *Je parler-ai*, "I shall speak," *tu parler-as*, *il parler-a*, *nous parler-ons*, *vous parler-ez*, *ils parler-ont*. These are the terminations of the present of the verb now mentioned, *J'ai*, *tu as*, *il a*, *nous avons*, *vous avez*, *ils ont*.

The French language has various modes of expressing futurity by combinations of entire words into set phrases. The verb *devoir*, which signifies to be obliged from duty, is employed for this purpose, as *Je dois faire cela*, "I am to do that." The same verb continues in other instances to retain its full original meaning. The verb *aller* is used for a similar purpose; as, *Je vais lui rendre mes respects.*

In the English language combinations of this sort are the only futures, and they are often used in such a manner as to express something more than futurity. We have thus a beautiful intermixture of their original meaning with their modern application. The verbs "will" and "shall" are most commonly used, but they are not indiscriminately applied to signify futurity. Each of these verbs is employed to signify the resolution of the speaker, or simple futurity, according to certain habits of collocation with certain nominatives. "Will" in the first person, and "shall" in the second and third, signify resolution. Simple futurity is expressed by "shall" in the first, and "will" in the two others. The simple future is as follows:

"I shall," "thou wilt," "he will."
"We shall," "ye will," "they will."

The future of determination is,

"I will," "thou shalt," "he shall."
"We will," "ye shall," "they shall."

The perplexities occurring in the use of these auxiliaries, in consequence of the tendencies of the Irish and Scotch being different from those of the English dialect, which is the acknowledged standard, may be avoided, if we always recollect that it is not the resolution of the *person spoken of* that they are at any time employed particularly to express, but of *the speaker*. "Will," therefore, is employed for simple futurity in the second and third persons, and is even appropriate where an event is mentioned that is opposite to the inclination of the person who is the subject of the assertion. We say, "if you become obnoxious to the criminal law, you *will* be punished." The word "will" does not here imply intention or even consent, yet it is appropriate, because "shall" would imply constraint or authority on the part of the speaker. It is also to be remembered that, in mentioning any thing future with respect to ourselves, although it should be the effect of our intention, this does not render it proper to use the auxiliary verb "will." "Will" in the first person always expresses emphatic resolution, implying the apprehension of difficulty or resistance from others. If another has said, "you shall not," a man replies, "I will;" but in expressing the common acts which are to fill up our future time, we say simply, "I shall go home," "I shall tell you the whole matter when we next meet."

But there are occasions, independently of provincial solecisms, in which "will" may be employed in the second and third person to express the resolution of the person spoken of, and "shall" in the first, the resolution of some other. Observing another person obstinate, we may say, "It seems you *will* do it, and cannot be prevented." If another person has said to us, "You do not admire my friend, but you *shall* treat him civilly," we may reply, "perhaps I may, but you are mistaken in telling me that *I shall.*" These last modes of speaking, however, are awkward, and require an uncommon emphasis to be laid on the respective auxiliaries, in order to express the full meaning of the speaker. It is therefore more elegant to employ more explicit phrases, as, "it seems you *are resolved* and cannot be prevented." "Perhaps I may, but you are wrong in supposing that *I am to be forced.*

Our language, like every other, has various words and phrases which express futurity along with something more, as "I intend," "I am obliged," "I am likely." We have also a phrase for expressing simple futurity in the use of the substantive verb followed by an infinitive, as "I *am to* go," "he *is to* come in my stead." We have the phrase, "to be about," which literally means to be somewhere in the neighbourhood of an action, and is by conventional application appropriated to the expression *of near futurity.*

### 5. *The other Tenses.*

It is unnecessary to consider particularly the other modifications of tense, such as the *plu-perfect*, and the *paulo-post futurum*, or to enter on an analysis of the phrases formed by the combinations of the auxiliaries "have," "do," "shall," "will," "had," "did," "should," "would," "shall have," "will have," "should have," "would have," to which grammarians add "can" and "could," with their combinations. All these are conducted on the same principles with the combinations already explained.

Combinations of meaning, which are expressed in our language by the junction of several words, are expressed in Greek and Latin by means of syllables added to the radical letters of each verb, and forming with them entire words; as *amarem*, "I should love" *amaverim*, "I could love," or "I would love," (translated in our grammars "I may have loved,") *amavissem*, "I should have loved."

Dr Adam Smith, in the comparison which he makes betwixt the ancient and modern languages, considers the former as deriving, from the use of syllabic variations, a great simplicity, compared with those which fulfil the same purpose by means of auxiliary verbs. He thinks it more natural, after men possess a word for representing an event, to express the modifications of that event, in respect to person, number, and time, by altering the word, or giving various terminations, than by inventing separate words for the modifications intended. He considers the formation of a separate word of this kind in the same light with the formation of the substantive verb, that is, as a great effort of abstraction, which could only be the result of refined metaphysical speculation. His observation, however, loses all force, when we recollect that a termination is as really a sign as a word is; and that the general employment of a termination or any other modification, on a number of analogous occasions, is the same kind of mental exertion as the prefixing of a sign of this variation in the form of a distinct word. It is not necessary to suppose that a general word in the form of an auxiliary verb is first contrived and perfected in all its parts, and then applied to use. It may first be used in a single form suggested in a moment of need, while we are using the verb descriptive of the event. It may be afterwards readily transferred to an association with a different verb; and this facility of association is the same, whether it is a subjoined syllable or a separate word. The distinction betwixt syllables and separate words is probably not fully acknowledged till mankind commit language to writing. The fact however is, that verbs, which previously existed as expressions for separate assertions, are afterwards adopted as auxiliaries; a circumstance which removes still farther the necessity of ascribing the invention of them to refined metaphysical speculation.

Dr Smith further considers this mode of expressing the modifications of the verb in the ancient languages as conferring on them a great advantage over the modern languages, in respect of brevity and force. But this brevity is often a deception, arising from the prejudices attached to the appearance of written language. That author adduces as an exemplification of his remark the Latin word *amavissem*, which expresses a modification of thought, which in English requires no fewer than four, being translated by the phrase, "I should have loved." The English phrase, however, is pronounced with equal facility and dispatch as the single word *amavissem;* it consists of the same number of syllables, and these have no greater character of perplexity or tardiness in the one case than in the other. The Latin syllables, in this instance, nearly correspond to the separate English words; *am*, signifies "love;" *av*, "have" with "ed;" *iss*, "should;" an *em*, "I."

Hitherto we have been occupied with those parts of the verb which serve as the copula in the composition of a sentence, and which, in technical language, are called *indicatives*. This appellation, however, if it is not a name for a mere form, if it has any scientific meaning, must be extended to some forms which have usually been considered as belonging to the subjunctive mood, as they are not confined to the purpose of subjunction, but sometimes form the only verb in a sentence: as *Illi potius quam alteri* CREDEREM. MALUERIM *te quam ullum alium imitari. Si cum hoste dimicâsset* PERIISSET. The words here marked in capitals have the full force of the indicative; that is, they convey affirmations; they indicate new connections of ideas, intended to be impressed on the mind of the person spoken to. They are therefore improperly distinguished by the title of *subjunctives*, if this implies that they are fitted only to maintain a subordinate rank in the composition of a sentence. Some further observations will be made on them in the sequel.

### SECT. IX. *The Subjunction of Sentences.*

EVERY improved language possesses various contrivances for the subjunction of certain sentences to others. In every continued discourse, some are distinguished as of greater importance, and holding a more eminent rank than the rest. These others may be equally necessary to the full elucidation of the subject; but their utility arises from their subserviency to the developement of the former. Some sentences are preparatory, and contain propositions which are said to be premised. Others are inserted as constituent parts of more prominent sentences. This last operation may be denominated *subjunction*.

A whole sentence is capable of being used as a noun, and applied to every species of syntax competent to the noun. Sometimes the sentence retains the same form as when it stands unconnected. It may, for example, be made the nominative to a verb. This use of sentences is of frequent recurrence in treating of the subject of language, as in treatises on universal grammar, in which sentences, as such, are the subjects of discussion. We can make a sentence by conjoining the three words "this is right," and we can then make it a nominative to the verb "is" by saying, "*This is right* is a short sentence." We can also make it an accusative to the verb "think," or the verb "say:" "He thinks or he says *this is right*."

Sentences may also be rendered parts of other sentences, by means of slight changes on some of the words composing them, or by the interposition of other parts of speech, contrived either for simple annexation, or for pointing out at the same time the particular relation in which the subjoined sentence stands to the whole.

Subjunction is of two kinds; subjunction to nouns, and subjunction to sentences.

#### 1. *Subjunction to Nouns.*

A sentence is subjoined to a noun, when it is employed for the same purposes of amplification or qualification as the genitive case or the adjective. This is done by using, instead of the nominatives "he," "she," "it," or "they," the relatives "who," "which," or "that;" as in the sentences, "Men who speak little are esteemed prudent:" "A man who commits murder deserves death:" "Men who speak ill of their neighbours are dangerous:" "Men who are capable of hypocrisy are not to be trusted." Here each of the sentences introduced by the relative "who," limits the assertion to a definite part of the general class of beings represented by the nouns "men," or "man."

It may be objected that the words, "who speak little," do not of themselves form a significant sentence. If this is the case, however, it depends entirely on the nature of the nominative "who;" and it may be remarked, that this nominative has the full meaning of the pronoun "he;" "he speaks little" is a complete sentence, though, in order to be made intelligible, it requires some previous knowledge of the person referred to by the word "he;" but the case is the same with innumerable entire sentences in language. "Who" implies the meaning of "he," and something more; it implies a mark that the sentence of which it is the subject is subjoined to a noun, and is thus an entire sentence, with something additional.

The author of the article GRAMMAR, in the *Encyclopædia Britannica*, ingeniously analyses the relative into the preposition "of" preceding the pronouns "he," "she," "it," or their plurals, or oblique cases. When thus analysed, this word "of" must govern, not the pronouns separately, which in fact are sometimes nominatives, but the subjoined sentences to which they belong. He shews that Mr Harris was deceived in supposing that the relative might be resolved into the third personal pronoun preceded by the conjunction "and." The phrase "Men who speak little," may be resolved into "Men *of they* speak little." Readers who are not accustomed to such analyses, and who regard the present habitudes of language as exclusively significant, may imagine that this analysis renders the sentence unmeaning. But, if we could suppose that the preposition "of" were one of those which govern nouns and sentences indiscriminately, we should find that the uncouthness of this paraphrase does not render it unintelligible. To these the words "before and after" belong. We can either say "before his dinner," or "before he had dined." It is sufficiently supposable that our language might have been so constructed as to put it in our power to say, not only "the time of dinner," but "the time of he dines;" and to say not only "men of few words," but "men *of they* speak little." In this paraphrase we shall have an intelligent analysis of the relative.

In sentences thus subjoined, the relative may sometimes be the nominative, as in the examples which we have given; or it may be the accusative; or it may be subjected to any other regimen competent to the noun. We may say, "A man *whom* the world admires." "A man *whose* veracity is unimpeached," or "A man *of whom* all are forced to speak well.

It is also to be remarked, that the noun to which such sentences or clauses are subjoined, may occupy any place in the larger sentence that is competent to a noun; it may form either part of the subject, or of the predicate. We may either say, "The man *who* loves his country deserves honour," or "the world respects Cato as a man *who* loved his country."

When we attempt to reduce sentences to a precise and uniform theory, the following question will arise. Is the verb, when thus subjoined by means of the relative, actually used for assertion? or is it deprived of this power by the relative? and ought the indicative of the verb to be on that account considered as applicable to other purposes besides assertion? It seems unscientific to maintain that the verb, separately considered, performs in this instance a different office, since the whole change of application is produced by the power of the relative. It would be most advantageous to consider the office performed by it in real assertions and in subjunctions of this kind as possessing some character in common, and to consider the modifications to which it is liable as consisting in the differences of the nominatives. If to any of our readers there should seem to be a gap in this part of our theory, we should be happy to have the means of supplying it pointed out. But to us there appears to be no impropriety in calling this general character by the name of *assertion*. An assertion may be first made, and may afterwards be mentioned for the sake of reference. An assertion may be used as the definition of an object. Of this object we may speak, either by a single name, or by using the terms of the definition introduced by the relative "which." It seems rather incongruous to maintain that the definition in that case loses its character of assertion. The most that can be said is, that its office has been previously performed, and that it is now in this respect dormant. Its adaptation to that original application, even in the present connection, is certainly still apparent.

It is worthy of remark, that the place of a sentence thus subjoined to a noun often admits of being supplied by a noun in the genitive, or by an adjective. The meaning expressed by the phrase, "A man who is capable of hypocrisy," may be expressed by the phrase, "A hypocritical man;" therefore a new theoretic question arises, does the adjective "hypocritical" imply the copula used in assertion? Nay, the whole meaning may be condensed into a single noun. Instead of either of the preceding phrases, we may say, "A *hypocrite* is not to be trusted." Does the noun "hypocrite" imply an assertion? Then it will follow, that the office of assertion is not peculiar to the verb, but is included in the noun itself. This is so far true, that every noun is susceptible of a definition containing the indicative or asserting form of the verb. A noun signifying a compound idea may be defined by an enumeration of the parts of which that idea consists. A noun signifying a simple idea may be defined by pointing out the relation of that idea to various others, whether by resemblance, connection, or contrast.

In the progress of human knowledge, combinations and distinctions of ideas are created, which are at first expressed in propositions and afterwards by single words; and these words are not understood till the processes of thought which gave origin to them, and which were first expressed by asserting propositions, are comprehended. Condensed signs, however, are not attached to all the results of these mental processes. This is only done when they are to be frequently referred to or treated as the chief subjects of discourse. When only occasionally mentioned, they are expressed in a more circuitous manner. Instead of a single word, we on some occasions use a noun with an adjective, as "an honest man," "a faithful servant;" or a noun governing another in the genitive, as "a man of consequence," "a man of probity," "a member of parliament." Sometimes these modes of annexation are accumulated, as, "a wealthy citizen of London," "a man of the highest reputation." On other occasions, when the combination of ideas is less familiar, we describe an object, by attaching to a noun a regular sentence by means of the relative, thus; "a man *who* has, in a certain circle, the highest character for understanding."

Sometimes the relative is employed to introduce a sentence which is not intended to form a descriptive definition of any object, but part of a narrative conveying new information; as, "Peter, *who* had all the time *listened* to my words, now presented himself before me." This has the same meaning with two sentences connected by the conjunction "and," viz. "Peter had all the time listened to my words, and now presented himself before me." The obliquity which this use of the relative produces is but slight, and promotes an elegant variety of diction.

### 2. *The Participle.*

In the use of the participle we have a method of subjoining a descriptive sentence to the noun, which, with respect to briefness and extent of regimen, is intermediate betwixt the use of the adjective, or of the genitive case, and that of the relative. It resembles the adjective in the manner in which it is introduced, but always follows the particular verb to which it belongs in the regimen which it possesses as introductory to other words. Hence it is capable of annexing a train of ideas to the noun. We say "a case *bearing* an analogy to the preceding;" "a man possessed of fine sensibility;" and, in a mathematical theorem, "the square of the side of a right angled triangle *subtending* the right angle is equal to the sum of the squares of the other two."

After the remarks which we have made on the possibility of resolving the meaning of any noun into a definition, we can have little difficulty with the participle. It is obviously resolvable into an indicative sentence introduced by the relative: "A man walking" is resolvable into "a man who walks."

A designation formed by the annexation of the participle to a noun, differs from the use of a noun which contains the whole meaning, by approaching nearer to the form of assertion. It prominently exhibits the analysis of that meaning which in the corresponding noun is more condensed, and, like the relative with the indicative mood, it enables us to extend considerably our specifications.

The participle may, like the relative and the indicative of the verb, be used for immediate assertion, as well as for definition. Thus Hume says of Charles V. "At last the emperor, *dreading* a general combination against him, was willing to abate somewhat of his rigour."

We formerly observed that the indicative mood of a verb might be resolved into the participle with the copula: that "he walks" might be resolved into "he is walking." And we have now remarked, that the participle may be resolved into the indicative mood introduced by the relative; that "a man walking" might be resolved into "a man who walks." The indicative is of earlier origin, and therefore less complex than the participle. The participle is an ulterior accommodation in language, though, when once contrived, it has in some respects no greater complexity than an adjective, or the genitive case of a noun.

Participles are varied in their form and meaning, as they often express something more than the subjunction of the general meaning of a verb to that of a noun. They are employed to express time, and also to give either an active or passive character to the object expressed by the noun.

There are in most languages two participles, one of which has been called the present participle active, and the other the perfect participle passive. The former is distinguished in English by the termination "ing:" the latter, sometimes by a change in the vowel of the verb, but most frequently by the termination "ed."

The participle in "ing," however, is often used without any implication of tense, and therefore may be applied to the past or the future, as well as the present. When we say "Yesterday, the public attention was excited by an aeronaut ascending;" if the word "ascending" were necessarily present, it would contradict the expression of past time contained in the verb "was." Grammarians avoid that absurdity, by observing that the act was present at the time expressed by the verb, and therefore may be mentioned in the present tense, as the principal verb of the sentence gives its own tense to all the subordinate words. But this statement will not apply, otherwise we might as well use the expression, "The public attention was excited by an aeronant who *ascends*," or "who *is ascending*." And we might say, "I thought that he *ascends* in a beautiful style." These phrases would be condemned as not only chargeable with bad grammar, but with incongruity and absurdity. It is therefore necessary to allow that the participle in "ing" is not restricted to any tense.

This participle, though generally active, is not confined to that voice. It is passive in such phrases as the following. "The house is *building*." "I saw a man *carrying* to prison." "I heard of a plan *forming* for his rescue." "A large sum of money is *owing*." The French sometimes use the passive participle *du* on the same occasions on which the English use the word "owing."

The participle in "ed," and others called perfect participles, belong essentially to the preterite tense. But with respect to voice they are not exclusively passive. The words "gone," "landed," "departed," "strayed," "decayed," "well behaved," "drunk," "mistaken," are active participles. The participle in *us*, corresponding to it in Latin, is also sometimes active; as in *tacitus* "silent." Although these words may appear to express quiescent qualities, they are such qualities as the action produces in the agent, and not in an object acted on.

### 3. *Subjunction to Verbs or to Sentences.*

An assertion is sometimes employed for the purpose of being subjoined to a verb. This is for the most part effected by the interposition of the parts of speech commonly called conjunctions, and which are to be considered in the sequel under the name of sentential prepositions.

Some assertions introduced in this manner are subjoined to the verb by a regimen bearing an exact resemblance to that of a noun governed in the accusative. The conjunction "that" is indeed interposed; a word not expressive of any particular relation, but merely a general sign of subjunction. Its sole office in this application is, to shew that the sentence which it introduces is subjoined. It is ingeniously and justly considered by Mr Tooke as the same word with the *pronoun* or *adjective* "that." Their identity of form is not the effect of accident, which sometimes produces an ambiguous coincidence in signs, which are of different origin, and intended to perform totally different offices. This is merely an instance of a word single in its origin and meaning, and applied on different occasions. It is in fact an adjective, agreeing with the sentence as a whole. In the sentence "I believe that he is come," we take the subjoined part "he is come" as an object, and say with respect to it "I believe that." Hence it is in Latin *quod*, which is also the relative: or *uti*, or *ut*, which Mr Tooke with great probability derives from the Greek word ὅτι. This last is closely connected in its etymology with the article ὁ, ἡ, το, and the relative ὅς, ἡ, ὅν, and is in reality the neuter gender of ὅστις. The circumstance of being made introductory to a sentence is a variety of application. Hence it is on some occasions of this sort subjected to a variation in its form. When placed before a sentence, it is commonly called a *conjunction*, and thus is ranked along with some other words which have a similar destination. This form of subjunction is extremely familiar in all sorts of language, colloquial, historical, and poetical. "I hope *that* you are well." "The general saw *that* the enemy was too powerful for an attack in the open field, and concluded *that* it would be more prudent to harass him by the well-timed operations of partisans." In our language the conjunction is sometimes dispensed with: as, "I hope you are well." All these instances, whether introduced by the word "that" or not, as well as the corresponding ones in Latin and Greek, are placed in the same situation with a noun in the accusative. Thus, in the following Latin phrases, the verbs *dicit*, *vult*, and *timet*, have the same regimen. *Quid dicit? Dicitne nihil? Dicit quod sapis. Quid vult? Vult ut huc venias.—Quid timet? Timet ne discedas.*

This mode of subjunction is sometimes performed by the infinitive of the verb. "I suppose him to be sincere" is equally good English with "I suppose that he is sincere." In Latin it is far more common. *Dicit te sapere* is more agreeable to common use than *Dicit quod tu sapis.* This interchange of phraseology will be more particularly illustrated under the head of the infinitive mood, which will be delayed till we have finished the consideration of some other parts of speech subservient to the same end.

Sentences are also subjoined to verbs by the medium of conjunctions signifying particular relations. Some of them express hypothetical representation, as "if," "suppose," "provided;" others causation, as "because," "since;" others concession, as "though," "granting;" others time, as "while," "when," "after," "before;" others alternation, as "whether," and "or," (not the same application of the word "or" which is made of *vel* in Latin, but one corresponding to the Latin *an.*) These words, like the preposition, are interposed betwixt the verb and the words standing for the governed object, and they express a specific relation of the one idea to the other. They bring along with them various modifications of the form of the verb which they introduce. These will come into view under the next head, the Subjunctive Mood, which has received its name from the frequency with which it is thus applied. We shall naturally be led to inquire into its various forms and uses as compared with those of the indicative, and thus trace the comparative adaptation of both to the purposes of subjunction.

### 4. *The Subjunctive Mood, and other Forms of the Verb allied to it.*

The moods of the verb are different in different languages. Sometimes a mood in one language comprehends two or more of those in another. One of the most frequent is the subjunctive, such as it exists in the Greek, Latin, and French languages. In the English it is sometimes expressed as the indicative, sometimes by means of auxiliaries. The various applications of it, and the variety of translations which its parts receive into English, as adapted to the occasions on which it is used, render it a matter of some interest to discover what properties are common to it on all occasions. It so happens that we have exactly that number of varieties of it in Latin which corresponds to the number of the tenses in the indicative, and hence they have been distributed into tenses under the same names; the present, the preter imperfect, the preter perfect, the pluperfect, and the future.

This mood has been called subjunctive, from the circumstance of its being used in assertions which are subjoined by the relative and by various conjunctions. But this office is not peculiar to this mood. It is sometimes performed by the indicative, preceded by the relative or by some of the conjunctions, such as "before," "after," "when," "where," "while," "if," and the words by which these are translated into other languages. On some occasions of subjunction the two moods are used indiscriminately; *Si hic adest*, and *Si hic adsit*, are equivalent. We also, say, *Qui vinum amant*, or, *Qui vinum ament.*

It is equally true that the subjunctive mood is not restricted to this office, but may with equal propriety be on certain occasions used indicatively, that is, for expressing the leading assertion in a sentence; as, *Si cum hoste dimicásset*, PERIISSET. In this instance, the subjunctive mood in Latin when used subjunctively is translated into the English indicative, "if he *had* fought with the enemy," whereas that which conveys the assertion, which is the ultimate object of the sentence, receives a peculiar translation by means of the auxiliaries "would have:" *periisset* "he would have perished." This is remarkable in most instances, though not in all, of the translations of Latin subjunctives into English. When used subjunctively, they are translated by the English indicative; when used indicatively, they are translated by a peculiar phraseology.

They are translated indicatively, when introduced by the words, *qui, quoniam, cum, quanquam, si, etsi, quasi.* This takes place in all the tenses: *si venias* "if you come;" *si venires* "if you came;" *si veneris* "if you have come;" *si venisses*, "if you had come;" *si veneris* "if you shall come."

On some occasions they are translated into English by peculiar auxiliaries. *Uti* or *ut*, and *ne*, are the words which chiefly give rise to a translation different from the indicative in the subjunctive mood which they introduce, and this takes place only in the present and preter imperfect: *ut eas* "that you may go:" *ut ires* "that you might go." Yet *uti* appears to have originally been equally extensive in its meaning with the word "that," by which it is translated. It is not merely applied to denote the *purpose* of an asserted event, but to intimate other forms of subjunction: as *odisti ut amas*, "you hate as you love;" *ut veniebat* "as he came," or "when he came." *Ut* with the present and preter imperfect subjunctive, (as *ut amet* and *ut amaret*,) may be supposed to have been originally fitted for any general subjunction, and afterwards applied to express the subjunction of a purpose; or, *ut* may have been adopted for variety as a synonymous word with *quod*, in order to introduce a more special phraseology by performing a certain department of the same office. *Ut venias* may originally signify "that you come," and may be used as a noun in the ablative. *Quâ causâ hoc mihi dixisti? Hâc causâ, ut iterum venias.* In English, the same word "that" by which *quod* is translated is on such occasions used for translating *ut*, but the verbal expression is then varied by the introduction of the auxiliary "may." The production of the effect is expressed by the production of the *power*. This is sufficiently natural, as the effect implies the power. It is an accidental pleonastic idiom, probably adopted for the sake of distinguishing this form of subjunction from the form of it expressed by the particle "that" with the simple indicative.

The same observations apply to the introduction of the imperfect subjunctive in Latin, by means of the word *ut*. It gives the verb the same relation to the past which the former gives it to the present. It expresses the purpose, and it is to be remarked, that in both instances it renders the verb in the subjoined phrase significant of something subsequent in order and in time. The tense called the present subjunctive when introduced by *ut* is future, and the imperfect expresses something subsequent to a past event.

The present and the future subjunctive are sometimes used imperatively: as, *audiant meum sermonem*, "let them hear my discourse;" *doceas filios sapientiam*, "teach your sons wisdom." These have every appearance of being instances of ellipsis, in which *obsecro* or *precor te ut* is understood. The Italians often use the *infinitive* imperatively; as *non stringere la mia mano cosi*, "not to grasp (that is, "do not grasp") my hand so tight." This part of the verb expresses the simple act, or a connection which may be subjoined to another part of speech; and custom assigns to it the additional circumstances conveyed, as suited to the different occasions on which it is introduced.

The future subjunctive is applied imperatively, most probably on the same principles as the future indicative, and it is often translated by that part of the English verb; as *ne occideris*, "thou shalt not kill" The Latin phrase has however the additional advantage of being originally subjunctive, and thus possessing the same fitness to be used imperatively by ellipsis as the present tense of the same mood.

All these tenses are also occasionally used indicatively, and the application of them is so contrived that they express some modification of the simple assertion.

This more rarely happens with the present than with the others. Yet we have instances of such an application. Thus, in the ninth book of the Æneid, Nisus says to Euryalus,

*Si quis in adversum rapiat casusve Deusve*
*Te superess* VELIM.

"If chance or Providence should render the enterprise unfortunate, I wish (or I should wish) you to survive."

In like manner, in the 7th book, Juno, dismissing Alecto from the superior regions, says,

*Te super æthereas errare licentius auras*
*Haud pater ipse* VELIT *summi regnator Olympi.*

This part of the subjunctive, when thus employed, is translated by the auxiliaries, "can" "may," "should," and "would," and generally refers to future events.

The preter-imperfect subjunctive, when used indicatively, is translated by "should "or "would." *Illam si amaret, in matrimonium* DUCERET, "If he loved her, he would marry her." The preterperfect is used on similar occasions, and translated in the same manner. MALUERIM *illum quam ullum alium imitari,* "I would rather imitate him than any other man." It is a remarkable circumstance, that these three subjunctive forms, called the present, the preter-imperfect, and the preter-perfect, when used indicatively, are often applied to the future. This cannot be considered as accidental; for, when translated into the English language, which adheres to no form of expression as an appropriate version of the Latin word, but varies it as occasion seems to require, they retain the form of the past tense "would," and "should," even when the event spoken of can apply only to the future. It might therefore seem interesting to inquire what peculiarity the meanings of these expressions have, which should render them analogous to the past tense. We clearly see that there is a foundation for such an inquiry, when we advert to the import of some English phrases. "I may go," and "I might go," are radically future in their application. "I should go," is equally future with "I shall go," though not otherwise synonymous. "I can go," and "I could go," are also future, as applied to the verb "go." The analysis of these phrases is comparatively easy, as they consist of auxiliaries. We at once recollect that the future of a verb may be expressed by the present of a verb preceding it signifying preparation for futurity; and, as the present is only one instant, and therefore has been said by some metaphysicians to have no existence, we consider it as including some adjoining portion of time, (most generally a part of the past,) at least as great a range as gives us scope for that short exercise of memory which we confound with consciousness, and which is necessary for reviewing any event and enabling us to describe it. There seems to be no impropriety in describing by a past tense a present action at least that is to be discontinued. If the present may be thus delineated, it follows that the verb preparatory for the future may also be used in the preterite tense. "I might go," is future, as applied to the verb "go," though the preterite of the verb "may." For the purpose of tracing the source in this phraseology, it is of importance to observe that "may" and "might," which are different in their own tense, impress different characters on the future event which they are employed to introduce. Both of them express an uncertain or conditional futurity. But "may" signifies a state of greater preparation, and expresses a belief in the probability of the condition being obtained, and the consequent contingency taking place. "I may if you will," expresses greater readiness than "I might if you would." The latter phrase is either a hesitating way of intimating that we are partially prepared, on which account it would on some occasions be reckoned less polite; or signifies a hesitation, originating in our modified hopes respecting the condition, and then it is a more diffident manner of making a proposal. But the question recurs, why should the past tense be preferred for this uncertain mode of speaking of futurity? We should be happy to present a satisfactory solution of that problem. Although we had none to offer, we should have thought it unfair to decline stating the query. Perhaps this form of expression is used, because these uncertain expectations consist of images which possess the same sort of dimness with any object which retires to a distance in time or place, and consequently with an event which fades from the view by taking its place among ideas of distant recollection. Or, if this explanation is objected to as a refinement too subtile to have given origin to expressions so common, perhaps the choice of the past tense of the auxiliary on such occasions has proceeded from its signifying that the state of things preparatory for the future is discontinued: this want of extension to the present may conventionally be held equivalent to a less confident mode of representing a contingent futurity. But, though this explanation of the English phraseology now under review should be thought in some degree plausible, it might still be asked, How are such principles to be applied to the Latin subjunctive tenses? Do these tenses imply in their etymological structure all the force of the English auxiliaries? Did they possess that force in the intentions of the persons by whom they were first employed? Or are they mere general modes of stating a connection of ideas applicable to conditions and other subjunctions, as well as to conditional assertions? The difference betwixt these two methods of explaining them is perhaps merely verbal. If the subjunctive is an instrument intended to be applied indiscriminately to all connections of ideas, whether actual or hypothetical, the purpose fulfilled by it is the same, whether it consists in the want of some character belonging to the indicative, or in the possession of a superadded character, including the meaning of an additional sign. Even if it were acknowledged to be of subsequent invention, and on the whole more complicated in its form than the indicative; this is to be accounted for, not by its expressing more ideas, but by its later use, as applied to the purposes of human language. The English auxiliaries express something indefinite with regard to the events described; and the same thing is done by the subjunctive form of the Latin verb. But the variety of the English auxiliaries, as applied to translate the same Latin word, leads us to regard the Latin subjunctives as of less special meaning, and therefore partaking more of the character of general marks of annexation, which admit of being applied to a variety of purposes, the particulars of which are left to be inferred from the tenor of the discourse. If we knew the etymology of the ancient subjunctive forms, some light would be thrown on their history, but very little on their intrinsic nature. Words derived from the names of particular kinds of objects often become much more general; and, though they receive subsequent limited applications which render them again particular, they do not denote the same kinds of objects by which they were first suggested. The expedients adopted for varying general signs, and fitting them for expressing different particular meanings with precision, are entirely arbitrary, and often consist in an advantage taken of accidental original synonymes. This last stage of variation is that which has given the Latin language the form in which it is found in the writings of the classics. The varieties of phrase are not in general founded on corresponding differences in the direct etymological origin of the words. The indicative uses of the subjunctive mood therefore may on the whole be considered as elliptical.

The pluperfect subjunctive, when used indicatively, expresses a conditional assertion concerning the past. This is the meaning of it in the example already mentioned, *periisset*, "he would have perished." Sometimes it may be translated by "ought to have." Thus in the fourth book of the Æneid, after Dido's voluntary death, her sister says, *eadem me ad fata* VOCASSES, "You *ought to have* invited me to share your fate." This is a conditional preterite, and may be considered as implying "If this had been the character of past events, all would have been well." The past is subjoined to an implied regret, and resembles such an ellipsis as the following English phrase. "If I had but seen him before he died!"

The future subjunctive is justly considered as differing slightly in tense from the future indicative, by expressing the "future completion of an event." But it is not on that account deprived of the peculiar character of the subjunctive mood; nor can we think, with some, that it differs from the future indicative in tense alone. It is not used, in general, for the simple and unconditional assertion of this species of futurity. It is not probable, for instance, that it would be used for expressing the assertion in the following sentence: "As soon as you have finished your letter, I *shall have* finished mine." That the tense in this sentence may be literally expressed in Latin, the passive voice is preferred, as it supplies an indicative tense of this sort by the combination of the future indicative of the substantive verb with the past participle. *Quum literas tuas scripseris, meæ etiam* FINITÆ ERUNT. This combination is denominated in our grammars a future *subjunctive* of the passive voice. The cause of this denomination is, that it is similar in tense. It unquestionably belongs to the indicative mood, while the others coupled with it in our grammars are subjunctive. The future of the subjunctive is indeed like its other tenses used indicatively; but like these others it is limited to uncertain and hypothetical assertions.

The subjunctive mood of the verb is on the whole a generic form applied chiefly to two less general uses, viz. subjunction, and the assertion of uncertain or conditional connections betwixt different objects. The property which these two uses of the verb have in common is uncertainty. There is one use of this mood which we have not hitherto mentioned, as it did not require to be separately illustrated, to wit, interrogation; as in this phrase, *An sit quies scelerato?* This will be considered as an instance of subjunction by those who allow, what we shall afterwards more fully state, that an interrogative sentence implies the imperative of the verb "to tell." *Quis est* signifies *Dic mihi quis est*. From this it follows, as well as from the obvious nature of a question, that uncertainty is also involved in that application of the subjunctive. Its imperative application has been already stated to be an instance of subjunction by ellipsis.

In Dr Gregory's memoir *On the Theory of the Moods of Verbs*, contained in the 2d vol. of the Edinburgh Philosophical Transactions, there are some apposite observations on the application of the subjunctive mood to a great variety of phrases mutually analogous, which had occasioned some difficulty. That author considers the moods of the verb as formed for giving a direct representation of the feelings, intentions, or present actions of the speaker, and resolves them into a variety of affirmations in the first person singular. *Oro* or *jubeo* is, according to this theory, implied in the imperative; *dico*, in the indicative; *opto*, in the expression of wishes, and a variety of others on different occasions, as suited to the various applications of the subjunctive. From the great diversity of feelings and purposes which may actuate a speaker, he infers that the real moods are too numerous to be expressed by separate modifications of the verb without rendering language cumbersome and complicated; but that those which are most common are expressed in this manner, for the sake of giving a condensed force to the utterance of human thought.

The view which we have given of the moods of verbs, and of language in general, differs from the principles now mentioned. We have considered language as not originally directed to the object of expressing spontaneously and naturally our own thoughts. It executes our purposes, by arranging the signs of thought in that order which is in our opinion best fitted to influence another person; an object which may be sometimes most successfully accomplished by concealing our own sentiments. To express our mode of thinking is indeed a very frequent object of language, and naturally has certain contrivances adapted to it; but to tell that we are speaking or asserting, seems to constitute no part of its object in addition to the use of the signs fitted for performing that office. The author, therefore, acknowledges that his principles have not so full an application to the indicative as to the other moods.

With whatever degree of vehemence or delicacy men wish to express their feelings, they are provided with means adapted to their object. Significant gestures and tones independent of language may be employed. When it is thought proper to exhibit the same animation in the form of written language, syllabic imitations of involuntary exclamations are committed to writing, and are afterwards employed by rule. We sometimes execute the same purpose by placing our communicable ideas in such a point of view as tends to produce in others the feelings which occupy our own minds, sometimes by describing in more deliberate and explicit language the manner in which we are affected. Language is on other occasions fitted for expressing the feelings of the speaker by elliptical turns of phrase, in which more is at first meant than is verbally stated. These phrases are afterwards appropriated to the expression of specific feelings. Moods of the verb which were originally of a more general meaning may, by transpositions of words, or by an abruptness in the manner of their introduction, be subjected to such diversities as to become characteristic of the most vehement, the most rapid, or the most subtile modifications of sentiment. For example, instead of telling that we wish for the occurrence of a particular event, we may express the ardour of our wishes by the exclamation "oh." "Oh that he would return!" Or, without such an exclamation, we may say, "That he would return!" or, "That he would but return!" The Romans may be supposed to have at one time been in the habit of using the word *uti* in this manner, *Uti rediret!* But as this might have been ambiguous from being too general, and might be supposed by the hearer to signify some purpose entertained in the performance of another act, as, *uti rediret, veniam ei polliciti sunt*, another particle *nam* is introduced, to indicate that this kind of event is abruptly mentioned as an object of the wishes of the speaker. It may not be easy to shew why a particle equivalent to the English word "for" was preferred to any other; but, when habitually used in this connection, it becomes appropriate. It is thus that *utinam* becomes equivalent to "oh that," or "I wish that."

The Greeks have an optative mood adapted to the expression of wishes, though it appears not to be applied exclusively to that object.

The brevity and force thus created by means of the moods of verbs are effects of the contrivances of language which abound in all the different parts of speech. When a combination of ideas or an assemblage of thoughts or feelings becomes habitual, it receives an appropriate condensed expression. We complain of tediousness when an idea, which might have been expressed by a single word or a short phrase, is slowly brought out by means of a long series of words or of sentences. But when we have an unusual assemblage of ideas to express, no circumlocution is to be spared which may be necessary to give our language perspicuity, and the beauty of felicitous contrivance is often conspicuous in the invention of means for exhibiting thoughts, which servile imitators would either not have conceived, or not have attempted to express. Language is happily used, where those phrases and words which are rendered intelligible and appropriate by established usage are employed judiciously for expressing complicated ideas. They may be placed in a connection with each other fitted to create combinations which are still more complicated, and possess a character of novelty which is rendered necessary by the purpose of our discourse. In fine, the skill of a writer may occasionally be discovered by the use of simple signs, in such a fortunate succession as to the express, apparently by accident, some novel but well defined state of feeling and of thought. The expedients suited to these purposes are therefore not confined to the use of particular moods of the verb, and the act is not characteristic of their nature.

### 5. *The Infinitive Mood.*

We had occasion, in describing other parts of speech, to mention the *Infinitive* of the verb. We observed, that it is not an original word, nor the earliest form of the verb, but consists of the imperative in composition with a sign derived from some different source. In explaining the uses of the subjunctive mood we observed, that in the Latin language that mood with the introductory particle *ut* may have its place supplied by the infinitive. *Volebat ire* is equivalent to *volebat ut iret.* We shall now enquire more particularly into its nature and uses.

Both its etymology and application shew that it expresses merely the specific idea conveyed by the particular verb to which it belongs, in such a way that it can be used as a noun, by becoming the subject or predicate of a sentence, or part of either. It does not, like the indicative, appear to contain the copula, except when substituted for that mood by ellipsis, as it frequently is by Sallust and other authors in depicting scenes of bustling activity or striking interest. Hence it has by some been denied the properties of the verb, and considered as in all respects nothing more than an abstract noun. It is formed in Latin by adding to the radical letters of the verb, as existing in the imperative, the termination *re.* From *ama* we have *ama-re;* and from *doce, doce-re.*

This termination, being identical with the radical letters of *res* "a thing," seems to be exactly the same original sign, and in this application it retains the same meaning. *Ama* signifies "love;" *ama-re*, "love-thing," i.e. "love" considered as "a thing," or object of thought. In English the infinitive consists of the radical letters of the verb preceded by the word "to;" as "*to* love" and "*to* teach." Mr Tooke considers the infinitive as possessing the character proper to the verb, though he does not tell us in what this consists. He describes the word "to" as having the power to confer the verbal character on a noun. At the same time he considers it as originally the same with the verb "do," and as meaning "act," "effect," or "consummation." These suggestions are extremely obscure. It is not easy to conceive what influence the additional idea of "effect" or "consummation" could have, to impress the character of a verb on a word which is otherwise a noun. We must therefore leave the opinions of that author in the same ambiguous state in which we find them. On some occasions in the English language this prefixed word is dispensed with. As "we saw him *go* away," and "we bid him *write* to us when he arrived at the end of his journey." In whatever light the infinitive mood of the verb may be considered, we find that this form of it, as existing in the English language, has the same meaning and uses with the words formed by such terminations as the Latin *re*, and receiving the same appellation in other languages.

The following is the question which claims our present attention. Is the infinitive mood of the verb properly and in all respects a noun? Is *amare* "to love," for example, a word of the same signification and uses with *amor amoris* "love?"

We shall obtain the most advantageous view of the nature of this part of speech, by taking in detail a survey of the circumstances in which it resembles the noun, and those in which it deviates from it.

It resembles the noun in being used as a nominative to a verb; as in the following Latin sentence from Cicero, as well as in the translation of it into English: *Loquor de docto homine et erudito, cui* VIVERE *est* COGITARE. "I speak of a man of learning and erudition, for whom *to live* is *to think.*" It is also, like the noun, capable of being governed by an active verb; as *Oblitus est* SCRIBERE, "He has forgot *to write.*" On some rare occasions in the Latin language, an adjective is employed to agree with it as with a noun. Thus Cicero says, *Cum* VIVERE *ipsum turpe sit nobis;* also, *Totum hoc displicet* PHILOSOPHARI. Persius says, VELLE *suum cuique est.* Petronius, *Meum* INTELLIGERE *nullâ pecuniâ vendo.* In these instances *vivere* is used in the same manner as *vita*; *velle* as *voluntas; philosophari* as *philosophatio*, if such a noun existed; and *intelligere* is used as *intellectum*, the accusative of the noun *intellectus.* Sometimes it is employed as the genitive of a noun; thus Cicero says, *Tempus est* ABIRE, a phrase equivalent to *tempus est abeundi.* Sometimes as an ablative. Thus in Plautus, *Ego sum defessus* REPERIRE, *vos defessi* QUÆRERE.

In other respects, however, it differs from the noun. The concordance of an adjective with it in the manner now mentioned is a rare occurrence even in the Latin language, and does not take place in the English and others. The additional idea which the adjective would express is connected with the infinitive by a different sort of syntax. In Latin, *meum intellectum*, or *meam intelligentiam*, is more consonant to general usage than *meum intelligere.* We should not in that language say *bonum intelligere.* If *bonus* were employed, it would be along with *intellectus*, or some other noun; and, if the infinitive *intelligere* were employed, the additional idea would be conjoined by means of a part of speech which we have not yet considered, the adverb; in this instance, *benè intelligere.* In English we should not say, "my to understand," but "my understanding;" nor "a good to understand," but "a good understanding," or "to understand well."

When an agent is mentioned along with an action in the infinitive, it is not in the form of a noun in the genitive, as it would be if the act were expressed by a noun. We do not say *illius amare*, as we should say *illius amor*. Nor is it put in the nominative. Though we say *ille amat*, we do not say *ille amare*. The syntax of the infinitive is in this instance peculiar; the agent is put in the accusative: *Illum amare*. This arrangement does not arise from the regimen of a preceding word expressed or understood governing the noun in the accusative. The combination of the noun in this form with the infinitive sometimes constitutes a phrase which is used as a nominative to a verb. In the Greek language this combination is sometimes even used as a noun in different oblique cases in which it has an adjective agreeing with it. Thus Anacreon says,

Σὺν Τῼ δε ΠΙΝΕΙΝ ῾ΗΜΑΣ
Εὔδουσιν ἁι μέριμναι.

The accusative here only intimates that the noun and the infinitive occupy the place of a subjoined sentence. In English, when the phrase is to bo employed as a nominative to a verb, we use the noun preceded by the particle "for," which may be reckoned equivalent to an oblique case in Latin. We say, "*for a man to tell a lie* is a sign of cowardice." We sometimes find this differently expressed in low and provincial dialects. "To," for example, is employed instead of "for;" as, "*To you* to deceive me was unbecoming." At other times the noun in the objective case is used without any preposition, as, "But *him* to think that he was entitled to any credit was ridiculous."

When an *object acted on* is mentioned in connection with an act expressed by the infinitive, or when the name of an object referred to, and usually governed by a verb in some oblique case, is introduced, it is not put in the genitive as when it follows a noun signifying the same action. In this respect the infinitive retains the regimen of the verb to which it belongs. We say *amor uxoris*, for, "the love of one's wife," or, if the person entertaining this affection is already mentioned in the genitive, the object of it is introduced by a preposition in such a phrase as *amor illius erga uxorem*. But when the infinitive *amare* is used, it governs *uxorem* in the accusative. We say, *Illum amare uxorum*, "for him to love his wife." Sometimes an ambiguity might thus be created, because both the agent and the object are mentioned in the same case, and, on account of the common practice of inversion in the Latin language, the order in which the words are placed does not strictly follow that of their syntax. Hence the ambiguity of the famous response of the Pythian oracle to Pyrrhus, *Aio te Romanos vincere posse*, which admits of being translated, "I say that you can overcome the Romans," or "I say that the Romans can overcome you." In general, however, the connection renders the meaning of such sentences evident, and their perspicuity is assisted by the name of the agent being placed before the infinitive, or nearest to it, while the accusative signifying the object acted on either comes after, or is at a greater distance before it. The same thing takes place in the English language, although in it the infinitive differs a little in its mode of formation, as it consists of the prefixing of a separate word. When we use the noun "desire," we say, "the desire *of food*," *of money*," or "*of fame*." But "*to* desire *food*, *money*, or *fame*." The production of this mode of transition seems to us to be the great power conferred on a noun by the word "to" prefixed as the sign of the infinitive. In this therefore, according to Mr Tooke, the nature of a verb should consist. It might appear, however, that this is not common to all verbs, and therefore is not the characteristic circumstance which, when added to a noun, makes it a verb. In neuter and intransitive verbs it scarcely appears. Yet it is not always lost even in these. Every verb admits of a transition of discourse to some other ideas expressed by nouns, if not by direct regimen, yet through the medium of prepositions, and this is generally more or less altered when a word from being a noun receives either the form of assertion, so as to become a verb, or is transformed into that part of speech called the infinitive of the verb. Let us take, for example, the word "struggle," which is used both as a noun and as a verb. We say, "his struggles were strenuous and incessant." When we use it as a verb, we say, "he struggled with a powerful antagonist." We often also use such expressions as, "His struggles with his antagonist were obstinate." But in this last phrase we are conscious of a slight defect; and, although the brevity and manifest meaning of it may in general enable it to pass without censure, an accurate writer will prefer the introduction of a verb for the purpose of completing the series of words demanded by the syntax. It will be felt more strictly agreeable to the import of the different materials of language to say, "the struggles *which he maintained* with his antagonist were obstinate." It is also to be remembered, that even the least transitive verbs differ from nouns by having all qualifying ideas conjoined with them, not by adjectives but by adverbs, and that in this particular the infinitive mood follows the law of the verb; we say, "a *violent* struggle," but "to struggle *violently*." It is only in these peculiarities of transition, and in receiving adverbs instead of adjectives, that we can perceive any difference betwixt the infinitive of a verb and the corresponding noun. The former of these differences depends, in a great measure, on the character of particular verbs, and both of them seem too slight to confer on the infinitive the same rank with the asserting verb, and to divest it of the character of a noun. This is more especially the case when we consider that it is often used without an adverb, and without any such transition as has now been described, but is never independent of some character of syntax which is common to it with the noun. With this statement of the facts, we leave the argument to the consideration of our readers. We deprecate, in the mean time, any premature attempt to improve, in this or any other instance, the nomenclature of grammar.

The infinitive mood, in consequence of resembling in some particulars the noun, and in others the verb, is rendered fit for performing, in a manner peculiar to itself, the office of the subjunction of sentences to verbs. It may be made a question whether connections of words formed by means of it ought to be called sentences; but they certainly contain the meaning of sentences. We have already remarked that every noun may be resolved into a sentence, by means of a definition. But by the use of the infinitive, we have the parts of the sentence in a more distinct state than if they were all implied in a noun, though not so explicitly as in a definition, or even in a sentence formed by the subjunctive mood. It has thus a character intermediate betwixt the noun, with its regimen of genitives or the accompaniment of adjectives, and such subjoined sentences as have been already described. The same connection of ideas may be expressed by any one of the three following modes of diction.

1. By nouns alone, as in this sentence, "he wishes his son's *departure*."

2. By the infinitive mood, as when we say, "he wishes his son *to depart*."

3. Or by a sentence subjoined in the subjunctive, thus, "he wishes *that* his son *would depart*."

Here the verb "to wish" is that to which the other ideas are subjoined; and the verb "to depart" is that which is variously implied in the subjoined series of words.

The preference of one of these to another will sometimes be dictated by convenience, according as the intention of a writer is to study brevity, or to indulge in minuteness of detail; and sometimes there will be so little foundation for any particular preference, that the choice will be left to fancy, to habit, or to the love of variety. Sometimes a sentiment expressed in one of these modes in one language requires a different one when translated into another. *Credo te sapere* may be translated "I believe you to be wise;" but *dixi te sapere* cannot be translated "I said you to be wise;" the infinitive is here to be laid aside, and instead of it, a sentence must be subjoined by means of the word "that." "I said that you were wise."

We generally find it more eligible to use an infinitive than a noun, when we have occasion to connect with the meaning of the word any considerable variety of circumstances. We say "murder is a heinous crime;" but when we mention the agent and the object, we prefer using the infinitive mood, we say, "for a son *to murder* a parent is a heinous crime." This is a more complete expression than "the murder of a parent by a son." Indeed this last phrase evidently requires a verb or a participle to make it complete; thus, "the murder of a parent *committed* by a son, is a heinous crime;" and, as this makes the phrase verbose and tedious, it is better to say, "for a son to murder a parent is a heinous crime." In the Latin language, this idea would be most conveniently expressed by the subjunctive mood preceded by the particle *ut*. *Ut filius parentem interficiat nefas est*. It is but seldom that the mention of the agent is combined with the use of the infinitive, when the combined phrase is to be made the nominative to a verb. Such expressions as *filium interficere parentem nefas est*, are sometimes used, but they are inconvenient and ungraceful, and therefore not common.

The infinitive mood is varied in respect of tense. That form which is called the present infinitive is in reality of no tense. It is pure, absolute, and aoristic. It may be employed without the implication of time, and it admits of being applied equally to past, present, and future transactions. The remarks which we have made on that part of the *indicative* mood called its present tense, will suggest sufficient proofs of this fact; and the subjects are so nearly analogous, that it is unnecessary to bring forward particular illustrations of this point.

The infinitive in the past tense is, in the Latin language, fully expressed by the termination *isse*, which is nearly allied to the pluperfect subjunctive, a circumstance probably arising from the coincidence of their use as consisting in a subserviency to subjunction.

The future infinitive, both in Latin and in English, is formed by circumlocution. In Latin the general infinitive of the substantive verb is, for this purpose, conjoined with the future participle. *Iturum*, or *iturus esse*. In English it is constructed on similar principles. We say "to be about to go." We sometimes merely use the general aoristic infinitive after a verb which implies a reference to futurity, as "I expect him to go." In expressing such ideas, however, we frequently reject the infinitive as not well fitted for our purpose, and in its stead employ a sentence in the future indicative, subjoined by the word "that;" as I expect that he will go."

Similar principles are discovered in the formation of the tenses of the infinitive in the passive voice.

### 6. *The Gerund and Supine.*

The *Gerund* is a part of speech nearly resembling the infinitive, but tending more strongly to the noun, both in form and syntax. Like the noun, it is governed by prepositions, which the infinitive, at least in the Latin and English languages, is not. We say "much harm is done to the constitution *by drinking*." In Latin this idea is expressed by the ablative of the gerund (*potando*.) The infinitive is sometimes thus used without a preposition, as in a passage already quoted from Plautus, *Ego sum defessus reperire, vos defessi quærere*; but the gerund is, in almost every instance, better adapted to such purposes. Such passages contribute to show to what extent the infinitive may be used as a noun; but the infrequency of that mode of employing it, and the frequent use of the gerund, prove to us that differences in the forms of words, or parts of speech, often consist in a different extent of adaptation to particular purposes, and that the characters of some pass almost insensibly into those of others.

The gerund differs from the infinitive in not admitting the mention of the agent in equally close syntax. It does not even, like the noun, admit of the annexation of this or any other idea by a genitive or an adjective, nor has it any power analogous to that which the infinitive has of taking an accusative before it, to signify the agent. The gerund therefore is employed only when no mention of the agent is required, or when this is done by connecting it with some other word in the sentence, as when we say "*men* hurt themselves *by drinking*."

The gerund takes the regimen of the verb with respect to the nouns which it introduces. In Latin we say *potando vinum*; and in English, "by drinking wine." The same word may however be also used as a noun, and then it may take an adjective and govern the genitive; as "by *the* drinking *of* wine." The difference betwixt the word in "ing," in these two modes of employing it, is analagous to the difference betwixt the Latin gerund in *dum*, and the noun in *-tas*, or in *atio* or *itio*, formed from the verb. Instead of the preceding phrase, we may employ *potu*, or *potatione vini*. The Latin word called the gerund also admits of being used as a noun; we can say *potando vini*, as well as *potando vinum*.

The gerunds now mentioned have no accident of tense conjoined with them. We formerly observed, however, that the preterite form of the English verb, as used after the auxiliary "to have," has the nature of a preterite gerund. "Gone" is the name of an act completed. In the phrase "I have gone," it occupies the place of a noun governed in the accusative. In verbs of the transitive kind, while it is thus governed, it governs in its turn another noun, in the same manner as the other parts of the verb to which it belongs. We say "I have *given* them my promise." This is the nature of the word separately considered; but it is never used as a gerund in any other connection, and therefore grammarians have neglected to ascertain its proper character.

The word called a *supine* in the Latin language is, in structure and use, similar to the gerund, though not possessing all its inflections, and more limited in its application.

## Sect. XII. *Interrogation.*

Interrogation is a part of the object of language, performed by means of the verb, which remains to be considered. We have mentioned it (at p. 7.) in enumerating the forms of imperative influence which mankind, by means of language, exert on one another. Its peculiar object is, to obtain information from the person addressed. Mr Harris considers it as a modification of the use of the verb, and constituting a distinct mood, although the verb when thus applied should not possess a distinct form. It is a direct request, and therefore implies the imperative in a very prominent degree. "What is your name?" is another mode of saying "tell me your name." Interrogative words and interrogative arrangements of words are abbreviations implying the subaudition of the imperative of the verb "to tell." "Who is there?" means "tell me the person who is there."

Interrogative words implying a request for the particular mention of one circumstance that must be *selected* as true, from many others that are imaginable, have a close etymological connection with the relative, and sometimes consist of it unaltered. *Quis* in Latin is different from *qui*, but is evidently derived from it, and the variation which it receives is intended to intimate that the imperative of the verb "to tell" is understood; or rather it is so altered as to express this imperative distinctly and fully. In the Italian language, we have an instance of the employment of a different sort of word; "what do you want?" is expressed by *cosa volete?* which literally translated is "thing you want." But on most other occasions, in every language, the interrogative words are more or less allied to the relative. From *qui* in Latin, we have *quis? qualis? quando? quo? quorsum?* and from "who," and "which," in English, the words "when?" "where?" and "whence?" are evidently derived.

There are other questions which may be denominated *alternative* in their nature, because the speaker supposes two opposite statements, one of which must be true and the other false. A subject and a predicate are connected in a question, and the only reply that it admits of is, either an assertion of a connection betwixt the subject and this predicate, or betwixt it and a predicate which is completely the reverse. This may be also done by single words of affirmation or negation, rendered completely significant by their reference to the question. Interrogations of all kinds, however, imply the meaning of the imperative of the verb "to tell." The words of which they consist are a sort of subjoined sentences to this imperative, and are in some degree elliptical in their first creation, though generally rendered precise by receiving a peculiar form.

## CHAP. VII.

### *Of Adverbs.*

The term *Adverb* is considered by Mr Tooke as expressive of no character by which a part of speech can be distinguished. He considers the adoption of it as an artifice by means of which, under the colour of scientific order, grammarians have brought together a variety of words, originating in abbreviations and corruptions, and possessing in no other respect any common property. In this opinion we cannot acquiesce, although we are sensible that some confusion has arisen from the unskilfulness of grammarians in ranking among adverbs some words which ought to have been included under a different head.

Adverbs are words expressly formed for the purpose of subjoining an idea to that which is contained in an adjective or a verb. They are all capable of being annexed to verbs, and some of them to no other part of speech. From this circumstance the whole class has derived its designation. They never express an idea in so close subjunction as a noun governed by a verb in the accusative; they rather resemble nouns which are governed in the ablative, or phrases consisting of a noun with a governing preposition. They sometimes are employed to qualify the character of an idea expressed by an adjective or a verb. At other times they superadd some circumstance of relationship to objects which are capable of being separately conceived.

We cannot concur with those recent grammarians, who consider as instances of corruption the formation of adverbs by means of alterations made in the forms of words belonging to different parts of speech. They are words skilfully devised for fulfilling a definite object. They do not, as has been supposed, always arise from abbreviation. Although they are capable of being expressed by a plurality of words, this property is common to them with all parts of speech. Some of them are evidently abbreviations, while others have marks of being used as single words previously to any phrases into which they can be resolved. We have not even any demonstrative evidence that all of them are derivatives, and that none are original words.

Adverbs are divided into different species. Some express intensity, remission, or other modifications of attributes expressed by adjectives and verbs. Such are the adverbs "very" and "much;" as "very good" "much better," "much obliged;" also their comparative and superlative forms, as "more" and "most." The words "slightly," "little" "less," and "least," are of a similar nature. Some have considered the comparative and superlative degrees of nouns as condensed combinations of adjectives in their positive state with the adverbs "more" and "most," because they can be resolved into phrases thus constructed. "Richer" and "richest," are "more rich" and "most rich." But these adverbs may in their turn be resolved into other phrases containing adjectives. "More" is "in a greater degree," and "most" "in the greatest degree;" and, from the first consonant being common to them with the positive adjectives *magnus*, *multus*, "many," and "much," and their terminations being characterised by the consonants *r* and *st*, it appears evident that "more" and "most" are derivatives. The Latin word *maximè* is evidently derived from *maximus*, in the same manner as a great variety of adverbs is derived from adjectives.

Adverbs expressing modifications of qualities are generally derived from adjectives. Such are adverbs in *è* and *iter* in Latin, as *longè ingenuè*, *breviter*, *feliciter*. In English they are formed by the addition of the termination "ly," as in "shortly," "considerably," "wonderfully." This termination seems, as Mr Tooke remarks, to owe its origin to the word "like," of which it is an alteration, or, as he terms it, a corruption. It is sometimes used as an adjective termination in composition with a substantive, as in "princely," "kingly," which mean "prince-like" and "king-like." The adoption of it for distinguishing the adverb is entirely conventional, and the most profound investigation of its meaning will not lead us to a satisfactory conclusion on the nature of this part of speech. Yet the use made of this termination, and the nature of the adverb, are sufficiently apparent. They imply a notification that the idea expressed by the compound word is to be annexed in syntax, not to a substantive noun, but to an adjective or a verb. They are also capable of being attached to other adverbs; as "very nobly," "surprisingly well," "too uniformly."

The adverbs just mentioned are called *adverbs of manner*. Some of them merely express a general reference, and have the same relation to the words called demonstrative pronouns which others have to different adjectives.

Such are the adverbs "thus," "so," and "as." In Lancashire, instead of "thus" and "so," it is common to say "i' this'n," and "i' that'n."

There are numeral adverbs as well as adjectives. Such are "once," "twice," and "thrice." These belong to the cardinal numbers, as expressing repetition. There are also adverbs which signify a mere reference to repetition, such as "first," "secondly," and "thirdly," and belong to the ordinal.

There are adverbs of local situation, as "here," "there;" and of local aspect, as "hence," "thence," "hither," "thither," "upward," "forward."

Adverbs of time, as "now," "formerly," "soon," "afterwards," "immediately."

It is unnecessary to enlarge on the nature of these words, or to point out the phrases into which they are resolvable, and of which they often are abbreviations.

The adverbs of *Affirmation* and *Negation* have been reckoned different in their nature from all the others. When the subject, the predicate, and the copula, are arranged in the order of assertion, no separate word is necessary to affirmation; but sometimes an adverb is conjoined, to call the attention of the mind with greater emphasis to the truth of the assertion. Such are the adverbs "indeed," "truly," and "certainly." If a question is asked which admits of an answer by the simple affirmation or negation, the answers in the affirmative may be given in English by such adverbs as "certainly," "even so;" or in Latin by *etiam*, *imo*, or *utique*. Sometimes a peculiar word, and one which is never used as an adverb in a sentence, is applied to this object. The English word "yes," is of this kind. "Yes," is considered by Mr Tooke as derived from *ay-es* "have" or "enjoy," and meaning "have or entertain that belief." The English "yea," the German *ja*, and the corresponding words in the northern languages, are derived from a similar source. It is therefore to be considered not as an adverb, but as an abbreviation for a sentence. The adverb "certainly," and others equivalent to it, become by ellipsis contractions for the same sentence. If we keep out of view the etymological origin of the words used on such occasions, and consider them all as containing an equally full expression of the meaning of the speaker, we must reckon them abbreviations for sentences; but wherever they are introduced into the body of a sentence, they are adverbs possessing the same properties as other words of that class. They signify that the assertions to which they are applied are not hypothetical, but in conformity to the nature of things.

The negative adverb expresses the absence of this conformity. The same word is in some languages either used singly as an answer to a question, or annexed to a verb in the formation of a sentence. The Latin words *minimè*, *nequaquam*, and *non*, are used in both of these ways. But in English the word is on these occasions subjected to a slight change. The adverb is "not." The negative answer is "no." This last is said to be of prior date, and derived from a verb signifying "I deny," or "I am averse;" but, whatever its etymological origin may be, it is, like the word "yes," a contraction for a sentence, with this difference, that the sentence for which it stands implies the force of the adverb "not," and thus reverses the meaning. "Not" has the same general character with the other adverbs: it modifies the verb, and thus forms part of the predicate.

A negative sentence is the reverse of the corresponding affirmation. Yet there is no general difference of character betwixt affirmations and negations. Affirmations are often as directly opposite to each other as to negations. "He is without," and "he is within," are directly contrary. Many assertions can be made equally well in the negative and in the affirmative form. "He is at home" is an affirmative sentence, and the same idea is expressed by these negations, "He is not from home," and "He is no where but at home."

## CHAP. VIII.

### *Of Prepositions.*

Differences of opinion have been entertained on the nature of *Prepositions*. It is easy to give a character which will apply to them all; but it has been found difficult to give one which will apply to them exclusively. Mr Tooke has been considered by some as solving every difficulty, by pronouncing them abbreviations of nouns or verbs. This author shews that many of them are of the same nature with some of those words which are called conjunctions, and considers that circumstance as proving the inaccuracy of this instance of grammatical distinction. In so far as *the idea expressed* has been represented as a ground of distinction, this author is correct. But when we abandon that system, and take the circumstances of syntax as the foundation of our classifications of words, we shall find that some distinctions which were formerly improperly accounted for are referable to satisfactory data.

The classification of the short words called particles appears to us defective, and we shall in the present instance introduce a slight variation from the common usages of grammarians. We shall apply the term preposition to a more extensive genus than our predecessors have done, by including under it some words hitherto called conjunctions. Those words which are usually called prepositions, we distinguish by the appellation of *Nominal prepositions*, because they are introductory to nouns; and the others by that of *Sentential prepositions*, because they are introductory to sentences.

### Sect. I. *Nominal Prepositions.*

Nominal *prepositions* have been described by many grammarians as "words which signify the mutual relations of objects." But these relations are equally expressed by every part of speech. Mr Ruddiman with greater propriety describes the preposition as "An indeclinable part of speech signifying the relation of one *substantive* to another." We prefer saying that it signifies "a relation subsisting betwixt the idea expressed by one substantive noun and that expressed by another." It is to be observed that, with the exception of the preposition "of" in English, and some rare expressions already alluded to under the head of the genitive case, a verb, adjective, or participle, is interposed between the first of the nouns and the preposition. The preposition "of" is as frequently employed immediately after a noun in English as the genitive case is in Latin; but such phrases as "Newcastle-*on*-Tyne," and "Ashton-*under*-line," are in very small number. The prepositions "on," "under," and all the others except "of," subjoin a noun to an adjective, a participle, or a verb; as "fit *for* use," "good *at* singing," "depending *on* his fidelity," "connected *with* the government." "He has gone *from* home, *along* the road, *to* a distant place."

Mr Tooke has shewn great learning and ingenuity in proving that the prepositions, both in ancient and modern languages, are derived from nouns or verbs. *Chez* he derives from *casa*, "a house." *Avec* from *avez que*, "you have that:" *Sens* in French, and *senza* in Italian, from *assenza* "absence:" The Latin *sine* from *sit ne*, i. e. *ne sit*, "let it not be:" The Italian *fuori*, the Spanish *affuera*, the French *hors*, (formerly *fors*,) from the Latin *foris*; and this from the Greek word θυρα, in the Doric dialect φορα, "a door or gate." "Through" is derived from a Teutonic word *thuruh*, signifying "a door or passage." *Ad* he derives from the past participle of the verb *agere*, by these steps of transmutation, *agitum*, *agtum*, *agd*, *ad*. He considers the English "to" as the same word with the verb "do;" and "till" as derived from "to while." "For" comes from a Gothic word signifying "a cause;" "of" from *afora*, "progeny;" "by" from *be-on*, "to be;" "with" from *withan*, "to join;" "betwixt" from the imperative "be," and *twos*, the Gothic word for "two." "Before," "behind," "besides," are from the same imperative, conjoined with nouns which are either still separately used, or have left familiar traces in different forms. "Beneath" is from an old word *neath*, signifying "bottom;" "under" from *on* and *neder*; "beyond" from *geond*, which has the same meaning with "gone" or "past." The termination "ward," which is used both in forming adverbs and prepositions, is from the Saxon verb *weardian*, "to look at," which also gives origin to the word "regard." "Athwart" comes from *thweorian*, "to wrest or twist;" "among" is from *gemengan*, "to mix;" "along" means "on long," i. e. "on length;" "round" and "around" come from a word signifying "a circle;" "near" from *neahg*, "neighbouring;" "instead" is "in station," or "in place;" "down" is from *dufen*, "to dive or dip;" "up," "upon," "over," "above," he derives from *ufa*, "high." The same sort of investigation has been with considerable success applied to the Greek prepositions by Mr Bonar, in the 5th volume of the Transactions of the Royal Society of Edinburgh, and by Professor Dunbar in a separate work on the subject.

The grammatical system founded on these etymologies is in a great measure the contrivance of Mr Tooke. Some of his etymologies have been called in question by Mr Bonar and others. The author of the article Grammar in Dr Rees's *Cyclopædia* attempts to controvert the greater part of them in support of a different system, in which he traces the modern languages of Europe to an Oriental origin. Some of Mr Tooke's etymologies however are unquestionable; and it is of great importance to observe, that the author has shewn that all prepositions are resolvable, *with regard to their meaning*, into nouns or verbs. The same ideas may be expressed by all these parts of speech. This property is independent of any opinion that may be formed regarding their particular etymology. "From," for example, may have its place supplied by the noun "beginning." "The figs came from Turkey," means "The figs came *beginning* Turkey." "The lamp fell from the ceiling," "The lamp fell *beginning* the ceiling. "The lamp hangs from the ceiling," "The lamp hangs *beginning* the ceiling."

Mr Tooke's opinion was, that prepositions represent objects in the same manner as nouns. This is denied by other authors, who proceed on the presumption that nouns are the names of *things*, but prepositions the names of the *relations* of things. And some have derided the absurdity of pronouncing things and their relations to be the same. It might however be maintained that, as variety is essential to the existence of human knowledge, its objects wholly consist in relations. If there should be any difficulty in conceding that point, it ought to be remembered, even in a grammatical view, that the relations of things may be expressed by nouns as well as by prepositions, and that therefore no distinction betwixt these two parts of speech can be founded on such data. Mr Tooke, however, is not content with observing this coincidence betwixt nouns and prepositions. He considers prepositions as invariably derived from *concrete* nouns, or verbs containing these, and insists that they are the names of substantial material objects. The preposition "through," for example, being according to him derived from a word signifying "a door," carries along with it the full meaning of that concrete noun. This statement has been supposed to favour the system of materialism, and perhaps it was so intended; but it is in itself too inaccurate, or at least imperfect, to lead to any general conclusion. If the whole meaning of the concrete noun is retained in the prepositions thus derived, it is only in the form of allusion. A language is not pure and perfect till the allusion itself disappears, and till the word is employed to express an appropriate and well-defined degree of generality, independently of the concomitant ideas contained in the subject from the name of which it has been borrowed. "Through" expresses only one property of a door, and a property in which it resembles many other objects which have different names. This preposition is indeed equivalent to a noun, but it is to a more general one than that which suggested the term. The noun to which it is nearly equivalent is "passage," or "medium."

It is from its properties in syntax that the preposition must take its rank among the parts of speech. In this respect it deviates from the noun. When, instead of the preposition, we employ simply a substantive noun, as in the examples formerly mentioned, in which the noun "beginning" was substituted for the preposition "from," the sentence labours under an awkward chasm. The meaning may be fully understood, but it appears to be imperfectly expressed. There seems to be as great a deficiency as if in an affirmative sentence we should omit the copula, saying, like a lisping child, or an unpractised foreigner, "That man good," instead of "that man is good." In order to complete the syntax, we must either use an additional word along with the noun thus substituted, or supply its place by a different part of speech. The force of those Latin prepositions which govern the accusative is, on the whole more completely expressed by a word which has the regimen of an active verb. This character will apply to all the prepositions of the English language, as they all govern the noun in the same form. Those Latin prepositions which govern the ablative must be considered as less transitive in their regimen. (See our observations on the Ablative Case, at p. 23.)

The part of speech to which the preposition is most nearly allied in the mode in which it is introduced, will differ according to the sort of words to which it is immediately subjoined. When it is subjoined to a verb, the verb will govern it nearly in the same manner as it governs the gerund of another verb in the ablative. *Trans* will be represented by *transeundo*; *per* by *perforando*, or *permeando*. The English preposition "from" might be represented by the Latin gerund *linquendo*; the Latin *a*, *ab*, or *abs*, by *abeundo*. The prepositions imply no such specification as is signified by any of the verbs with which, for the sake of pointing out the properties of their syntax, we have here combined them. It was necessary to make gerunds by combining them with verbs, and thus appearing to add to the ideas which they express rather than to explain them, because we have no verb exactly corresponding to the simple preposition. The preposition itself is the gerund, though indeclinable.

If the preposition is introduced by the substantive verb alone as the first word of the predicate, it will possess the syntax of a participle agreeing with the nominative which precedes. *Sub* will have the regimen of *subjacens* or *subjunctus*. *In* will approach to the participle *habitans* or *in-*

*clusus*, though more general in the idea which it conveys. "Out of," when used in such a sentence as "He is out of town," will also have the power of a participle, though we cannot name any word in that form to which, with respect to generality, it makes any approach. This cannot always be expected. If the office of a preposition were to be performed with equal advantage by the gerund or participle of a verb in present use, there would be in some respects no occasion for the prepositions themselves.

Here we trace the peculiarities of this part of speech. It is usually more general than any other to which it is allied. It is marked by a peculiar brevity, and by the absence of inflexion. Without the formality of significant terminations, prepositions possess all their force. They thus correspond to the rapidity of human thought, and to the subordinate rank of the ideas which they convey. They have been called the pegs and nails of language. This account of them is severely censured by Mr Tooke, and is inaccurate when intended to intimate that they differ from other words in not expressing ideas. Yet it is certainly true that the ideas which they express might often be left to be inferred from the other words of the sentence. They are not the central ideas in discourse. The preposition *secundum*, "according to," implies all the ideas expressed by the noun "harmony" or "agreement;" the word "from" those expressed by the noun "beginning;" "above" those of the noun "top;" "below" those of the noun "bottom." But such ideas are never interesting on account of any general properties of their own. We never have occasion to write dissertations on "tops," "mediums," "beginnings," "endings," "outsides," or "insides." Yet the frequent recurrence and consequent familiarity of these ideas, together with their subordinate character, render it desirable for us to express them with rapidity, by endowing them with all possible brevity of form. Words possessing this character render language copious and minute without incumbrance. They are the Ε'πεα πτερεεντα, the winged words, of discourse. Whether we consider them as always derived from other parts of speech of greater length, which a large proportion of them undoubtedly is, or suppose it possible that they have occasionally consisted of syllables thrown in at random, and afterwards adhered to as significant, in the same manner as almost all original words must have been produced, we see, in their general form and application, their excellent adaptation to the completion of language.

## Sect. II. *Sentential Prepositions.*

The *Sentential Preposition* is a sort of words generally numbered among conjunctions, and forming in elementary grammars more than one half of that list. But the conjunctions, as thus classified, are not susceptible of any common definition; and this proceeds not merely from their coincidence in use with words of a different kind, but from their dissimilarity to one another. That this disadvantage may be diminished, if not entirely remedied, we here give a separate consideration to those words which have the power of introducing subjoined sentences in the same manner as the words called prepositions have with respect to nouns. We denominate them *sentential prepositions*, in contradistinction to the others, to which we have given the designation of *nominal*. In some instances the same word serves for a preposition of both kinds. "After" is a nominal preposition in the phrase "after dinner," and a sentential preposition in the phrase "after we have dined." In other instances the word employed as a nominal preposition undergoes some slight alteration, or receives some addition, to distinguish its application as a sentential preposition. The Latin *cum*, ("with,") sometimes retains the same form when used for subjoining a sentence, and sometimes is transformed into *quum*. *Ante* and *post* are converted into *antequam* and *postquam*.

The nature of the general sentential preposition "that" in English, and *quod* and *ut* in Latin, has been already discussed. *Quam* is another, like these, of very general meaning. It is sometimes translated "as," sometimes "than." It then performs the part of a relative, and has the same relation to an antecedent adverb which the relative noun has to the noun antecedent. *Quam* has the same relation to *tam* as *qui* has to *ille*. *Tanquam*, from *tam* and *quam*, may be called a sentential preposition, but it differs from *quam* in being more particular, as including the antecedent adverb. Of this last kind are also the sentential prepositions *antequam* and *postquam*. *Antè* and *post* are used adverbially, and the Roman authors often disjoin them from the subsequent *quam;* as, Ante *autem huc venerat* quam *sperâssem*. It might appear that *quam* should be considered as giving the subjoined sentence the character of a noun, and the word *ante* or *post* as a preposition governing or introducing it in that state. It is however more agreeable to the analogy of language to consider *ante* and *post* as adverbs, and the compound words *antequam* and *postquam* as synonymous with *anteaquam* and *posteaquam*, formed from the adverbs *antea* and *postea*. Adverbs in general might be resolved into nouns in the ablative case; and a special sentential preposition, or one which implies the meaning of an antecedent adverb, would, on this principle, be resolved into the ablative of an antecedent noun and that of the relative. *Antequam* is equivalent to *tempore* ANTERIORE *illi tempori* QUO. *Ut* is also used as a relative; *sic* is often its antecedent when it introduces the indicative mood, and *ita* when it introduces the subjunctive. *Ut* has sometimes in itself the force of *sicut* or of *ita ut*, and, when no antecedent adverb is expressed, may always be considered as implying by ellipsis the meaning of one. The sentential prepositions *dum* and *quum* have the same relatien to *tum;* "when," "while," and "where," to the adverbs "then" and "there." The resemblance and near relation subsisting betwixt "when," and the adverb "then," have led many grammarians to give to both the common designation of adverbs. *Postquam*, *antequam*, and other analogous words, have also been denominated adverbs; and thus the whole of this part of grammar has been involved in confusion: but we shall see the difference clearly if we recollect that the words now mentioned are not attached to verbs to modify their meaning, or exhibit in themselves any concomitant circumstance, but to introduce a subjoined sentence. The word "as" is used both for an antecedent adverb, and a sentential preposition. It is an adverb in the phrases "*as* good," "*as* soon," and a sentential preposition after the adverb "so," "He did not come so soon *as* I expected." All special sentential prepositions might be resolved by an analysis similar to that which we have given of *ut* and *antequam*. We have not antecedents in the form of adverbs for them all, but we may express them by ablatives of nouns or of gerunds. *Si*, "if," implies the meaning of *ea conditione*, *eo casu*, or *supponendo*. *Quanquam*, *etiamsi*, *etsi*, "though," "although," (words of nearly the same meaning with *si*, and differing slightly in the occasions of their application,) imply the force of *concesso* or *concedendo*.

It is in fine to be observed, that the special sentential preposition and the sentence subjoined by it, taken as a whole, occupy the place of an adverb, or of a noun in the ablative case. In some instances we find single words in this form equivalent to such sentences. *Citò* is equivalent to *priusquam multum temporis preterierit*. In the following sentence, "He was appointed to the office *till the propriety of the continuance of that measure should be ascertained;*" the whole subjoined ideas marked in italics may be fully expressed by the single adverb "provisionally." When *ita* is used without any subjoined regimen, it is an adverb implying a reference to some assertion previously made, or some connection of ideas exhibited at the instant of speaking: When it is employed as the antecedent to *ut*, with a subjoined sentence, the whole sentence along with the *ita* and *ut* occupy the place of an adverb, or the ablative of a noun.

The following is Mr Tooke's account of the etymology of some English words belonging to this part of speech. "If" is from *Gif*, the imperative of *Gifan* "to give." The old synonyme "an," from *Anan* "to grant." "Unless," from *Onlesan* "to dismiss." "Though," from *Thafigan* or *thafian*, to "allow." "Without," from *Wyrthanutan*, to "be out." "Lest," from *Lesan*, "to dismiss." "Since," from the participle of *Seon*, "to see." "As" is *es*, a German word for "it," "that," or "which."

Some words are used as sentential prepositions which still retain the form of gerunds or participles; as "supposing," "provided," "providing that," "granting that." "Seeing," was formerly used in the same manner.

## CHAP. IX.

### *Of Conjunctions and Miscellaneous Particles.*

*Conjunctions* connect words or sentences on equal terms, without regimen or subjunction. They continue the syntax of the introducing word to that which they introduce. General words of this description are not numerous, and the purposes to which they are applied do not admit of great variety. One kind of them may be termed *Conjunctions of union*, as they unite the meanings of the words which they connect. Such are the English word "and," and the Latin *et*, *ac*, *atque*. Another kind may be termed *Conjunctions of alternation*, as *aut* and *vel* in Latin, and "or" in English. The negative "nor" is a conjunction combined with a negation. It might appear in its etymology the reverse of "or," but in meaning it is the reverse of "and." It is equivalent to "and not." In Latin this is also its etymology. It is not *non vel* or *ne vel*, but *nec* from *ne ac*, and *neque* from *ne* and *que*.

Sometimes the first of the nouns or verbs connected by conjunctions is preceded by a peculiar word. "Both" is used to precede words connected by "and;" "either" those connected by "or;" and "neither" those connected by "nor." It is natural to ask to what head "both," "either," and "neither" are to be referred. In the English language, their etymology might strongly lead a grammarian to refer them to the class of adjectives when they precede nouns, and thus make them equivalent to *ambo*, *uter*, and *neuter*. When they precede verbs, they might be reckoned adverbs, and in English would be equivalent to adverbs formed by adding the termination "ly" to the adjective, as if we said "bothly," eitherly," neitherly." They perform the office of an adverb referring to concomitance. In Latin the same word is used both as the preceding and the conjoining word. Et *ille et alter;* Et *venit et vidit.* It will be found, on the whole, that conjunctions are near akin to adjectives and adverbs. They are necessarily frequent in the use of language, and therefore have received an abbreviated form.

Some miscellaneous particles may be called *special conjunctions*, as including a more particular character of mutual relation betwixt the ideas contained in the words or sentences which they connect. Such are the words "also," "farther," "moreover," "but," "likewise," "yet," "notwithstanding," however."

## CHAP. X.

### *Of Interjections.*

The term *Interjection* is applied to those words which express by short exclamation certain overpowering emotions of mind. Such as *'Αι αι! Heu! Atat! Proh!* "Ah!" "Oh!" "Alas!"

This part of speech is treated by Mr Tooke with great contempt, as a brutish inarticulate sound which has as little to do with speech as the neighing of a horse, the barking of a dog, coughing, groaning, shrieking, or any other involuntary convulsion with oral sound. These words, however, though at first involuntary, are afterwards uttered from design. A man desirous of impressing another with a particular passion, first contrives to excite it in his own mind, and then utters the sound by which it is expressed. Hence corresponding syllables are committed to writing in works which depict human passions and manners. They belong to language, as language must include every sound addressed by one man to another, from the highest to the lowest state of mental cultivation. Interjections may be considered as a mixture of involuntary expression with social discourse. In the use of this part of speech, man is seen to rise from the character of an animal impelled by passion to that of a reflecting being, who displays intelligence and address in influencing his fellow creatures.

Sometimes words belonging to other parts of speech, and expressing definite ideas, are introduced abruptly to express emotion, and numbered among interjections; as "Amazing!" "Wonderful!" "Prodigious!" "Shocking!" "Horrible!" "Mercy!" "Pitiful!" "Woe's me!" Whether we call such exclamations as these interjections, or abbreviations by ellipsis, is of little importance. Their meaning is never ambiguous.

In the introductory part of this article we described language as essentially imperative; and the slightest reflection will shew, that interjections, in so far as they partake of the nature of social discourse, possess an imperative character.

---

Books of merit on universal grammar are but few. But numerous observations on the subject are to be found in all good and complete grammars of particular languages, and in the larger Dictionaries. Some parts of it are also occasionally discussed in books of metaphysics. The principal English and French works on this subject are the following: Monboddo's *Treatise on the Origin and Progress of Language*; Harris's *Hermes*; Beauzée's *Grammaire Générale*; *Grammaire Générale et Raisonnée*, par M. M. de Port Royal; Condillac's *Grammaire* in his *Cours d'etudes*; Tooke's *Diversions of Purley*; Beddoes *on the Nature of Demonstrative Evidence*; Pickbourne's *Dissertation on the English Verb*; Mr Dunbar's *Analysis of the Greek Verb*; Dr Gregory *on the Theory of the Moods of Verbs in the* 2d vol. of the *Transactions of the Royal Society of Edinburgh*; Mr. Bonar's *Essay on the Greek Prepositions*, in the 5th vol. of the same work; Dr. Jamieson's *Hermes Scythicus*; Beattie's *Essay on the Theory of Language*; Hutton's *Dissertation on the Theory of Language*; Dr Adam Smith's *Essay on Language*, (published with his *Theory of Moral Sentiments*); Mr Stewart's *Philosophical Essays*, Part I. Essay 5th; and the article *Grammar* in the *Encyclopædia Britannica*, and that of Dr Rees.*

* The Editor is indebted for this valuable article on Grammar to Henry Dewar, M. D. F. R. S. E.

GRANADA, a celebrated city in Spain, and capital of the province of that name, is pleasantly situated on two small hills, at the extremity of a beautiful and extensive plain. It was built by the Moors in the tenth century, and was finally reduced by the Spanish armies in 1492, after a siege of more than twelve months. At that period it is said to have covered a space three leagues in circumference, and to have contained 400,000 inhabitants, a statement unquestionably far above the truth. Its walls were defended by more than a thousand towers; and it was farther protected by two fortresses, on the summits of the two adjoining hills, each of which was capable of containing 40,000 men. These fortresses still remain, but the walls and gates of the city are demolished, and many of its finest structures in a state of decay. It nevertheless exhibits evident proofs of its former magnificence; and its appearance from a distance is described as peculiarly majestic. The plain before it is above 30 leagues in circumference, and about 1200 miles above the level of the sea, but so completely inclosed by mountains of stupendous height, as to have all the appearance of a delicious valley. It is watered by five rivers, and intersected by numerous rivulets and canals; covered with the richest meadows, forests of oak, plantations of orange trees, and sugar cane, fields of corn and flax, orchards of fruit-trees, and all kinds of vegetables; bounded on the north by the lofty Sierra Nevada, with the mountains of Elvira, and on the other side by successive amphitheatres of hills, agreeably planted with vines, olive, mulberry, lemon, and orange trees. It contains within its circuit not less than 52 towns; and in its centre appears the Soto de Roma, which is a beautiful wood of elms, white poplars, and ash trees, full of game, especially pheasants, more than a league in length, and half a league in breadth, and formerly the retreat of the Moorish kings. At the termination of this fertile plain, the city of Granada is perceived from a considerable distance, extending in the form of a half moon from the river, along the gradual ascent of a hill, its streets rising above each other, exhibiting a profusion of turrets and guilded cupolas; the summit of the whole crowned by the palace of the Alhambra, and the back ground composed of the majestic Sierra Nevada, covered with snow. But the splendid illusions, created by this distant view, are sadly dissipated by a nearer inspection of its fallen grandeur. It was formerly divided into four quarters, which may still be considered as distinctly marked, namely, the quarter of Alhambra, which principally contains that immense citadel on the mountain of the sun, and where the splendid palace of the Moorish kings is still in existence, and in a state of sufficient repair to impress the spectator with the most lively idea of its original beauties; the quarter of Albayzin, a kind of suburb on the rising ground, separated from the town by a rampart, and containing about 4000 houses; the quarter of Antiquerula, which has the appearance of another suburb built upon the plain, was peopled by the settlers from Antequera, and is principally occupied by dyers and silk-weavers; and the quarter of Granada which covers the commencement of the plain, and a part of the valley between the two mountains, and is the best built and best inhabited part of the town. The river Darro runs through the middle of the city, and empties itself into the Xenil, which passes near the walls. The extent of the whole town is much the same as it was in the time of the Moors, but it is thinly inhabited in proportion to its buildings; and the present population is only about 60,000. The streets are generally narrow, and the houses very inferior in their appearance to those of many other cities in Spain. Even those which surround the market-place are very despicable, few of the upper apartments having glass in the windows, and the shops below being very indifferently supplied with goods. But there are many fine buildings, handsome squares, extensive gardens, and beautiful fountains in different parts of the city. The El Campo is a large square at the entrance of the town, on the road from Antequera, and is partly occupied by an hospital, which is a large and handsome building. The Plaza Mayor in the middle of the town is very spacious; and is used for public shows, particularly the bull-fights. The Biva Rambla, a handsome area, 400 feet by 200, is embellished by an elegant jasper fountain, and has on one side the Alcaxeria, and on the other the Chancery; the latter of which has a very handsome front, ornamented with alabaster columns, and a range of windows with gilt balconies; and the former, an immense edifice without ornament, formerly the bazar of the Moors, still contains about 200 shops: these shops are so very small, that the owner, sitting in the centre, is able to reach whatever his customers may require, without rising from his seat. The cathedral is a very splendid but irregular building. It has a handsome dome resting on 12 arches, supported by 12 pilasters; and against these columns are placed the statues of the twelve apostles, in gilt bronze, as large as life. The vault is full of paintings, and two rows of gilded balconies run round it above the arcades. In this church are some of the best pictures and statues by the celebrated Spanish artist Alonzo Cano, and his pupil Pedro de Mena. The palace of the archbishop stands close to the cathedral, and is a very extensive mansion, and of a handsome appearance. But the most interesting and splendid object in Granada is the Alhambra, the ancient fortress or palace of the Moorish kings, described in a former article: (See Alhambra.) Though this noble structure is fast hastening to decay, and likely to become in a few years a heap of ruins, it is still viewed by travellers with the strongest sensations of wonder and delight. In a higher situation on an opposite hill, is another palace, called the Generaliffe, which was used as a retreat in the intense heats of summer. The rooms are floored with marble, and have streams of the clearest water rushing through them. It is surrounded by gardens, groves and orchards, planted with orange, lemon, and cypress trees, and provided with a multiplicity of transparent pools and crystal fountains. Most of the houses have fountains and baths in their courts, which, besides supplying water for domestic uses, moderate by their coolness the extreme heat of the climate in the summer season. In imitation of the Moors, the present inhabitants spread an awning over these courts to keep off the sun, and live there all the summer, eating their meals and receiving their visitors amidst its refreshing coolness. The environs of the city are delightful, and the shady walks on the banks of the Xenil, with others more wild and romantic on the Darro, afford the most refreshing and pleasing retreats. The sides of the hills around the city abound with caves resembling the trogledyte habitations in Abyssinia. They were originally employed as granaries for corn, but are now inhabited by gipsies, who are very numerous in the south of Spain, and are said to bear a great resemblance to the same class of people in England. Granada contains an university and an academy for mathematics, but they have no library, few masters, and scarcely any students. There is a royal manufactory for saltpetre and gun-powder; and several for woollen cloths and serges, which are said to employ about 7000 persons, and to consume 460,000 pounds of wool annually. Silk stuffs, such as velvets, sattins, and taffetas of a very durable quality, are made in the city, and a considerable quantity of ribbons, in the manufacture of which the spring shuttle used at Coventry is generally adopted, the only kind of machinery observed in the manufactories of the place. See

Jacob's *Travels in Spain*; Townsend's *Travels in Spain;* Laborde's *View of Spain;* and Murphy's splendid work, entitled, the *Arabian Antiquities of Spain*, Lond. 1815. (*q.*)

GRANADA, a province of Spain, sometimes called Upper Andalusia, is bounded on the east and south by Murcia and the Mediterranean, and on the west and north by Andalusia. It is situated between 36° 20′ and 38° North Latitude, and between 5° 5′ and 1° 30′ West Longitude from Greenwich. It is of a very irregular figure, approaching to the shape of a pyramid, with its base to the east on the kingdom of Murcia, and its apex to the south-west, towards the straits of Gibraltar. It is 58 leagues in length from the east to the south-east; and in breadth, in some places 8, in others 18, and at its base 28. The principal towns are Granada, the capital, already described, Malaga, Almeria, and Amunecar, three sea-ports on the Mediterranean; Guadix, Motrel, Morbella, Velez-Malaga, Baza, Vera, Ronda, Loxa, Santa-Fe, Huesca, Antequera, and Alhama. Its rivers are the Verde, Xenil, Las Feguas, Guadalentia, Guadavar, Guadalmeja, Rio de Almeria, Rio Frio, Guadelmerina, Darro, Guadix, Bravata, Marchan, &c.

The Moors having acquired possession of Spain, after the bloody battle of Xeres in 711, in which Roderigo, the last of the Gothic princes, was slain, Granada became a part of their empire in the south of the peninsula; and, in 1013, was chosen by Almanzor as the royal residence, instead of Cordova. In 1051, the family of Almanzor were deprived of the sovereignty by Joseph ben Taschphen, King of Morocco, who filled the throne with dignity and splendour. After his death, the kingdom was divided among a number of pretenders; but, in 1146, was again united under a prince of the family of the Almohades. Mahomed the First, one of the greatest of the Moorish princes, laid the foundation of a new dynasty in 1232, and raised the kingdom of Granada to its greatest degree of prosperity. While he kept on foot a powerful army for the defence of his dominions, he was equally attentive to promote the welfare of his subjects by the arts of peace. He regulated the revenues, administered justice, cultivated science, endowed hospitals, and laid the foundation of the Alhambra, the glory of Mahommedan Spain. Mahomed the Second succeeded his father, and was distinguished, above all the monarchs of his race, as the protector of science, and the patron of arts and commerce. His court was the resort of astronomers, physicians, philosophers, orators, and poets; and his own compositions in verse are celebrated by Arabian writers for their epigrammatic humour. He was succeeded in 1302, by his son of the same name, who resembled him in his love of literature, and his patronage of the fine arts; but, while he was engaged in war with the King of Arragon, an insurrection in his capital transferred the crown to his brother Almasser, a young prince of 25 years of age, celebrated for his progress in mathematical and astronomical learning; but who, yielding to the turbulent dispositions of his subjects, was in his turn supplanted, in 1314, by Ismael, Prince of Malaga. The kingdom of Granada, hard pressed by the Christian states in the north of Spain, and thus torn by a succession of intestine commotions, was fast approaching to its fall. Its sovereign Albohassen, availing himself of the discontents created in Castile by the accession of Ferdinand and Isabella, marched a hostile army into their dominions in 1482. Ferdinand, having procured a truce of three years, and quieted his rebellious subjects, became the aggressor in his turn; and aided by the dissensions among the Moorish chiefs, pushed his conquests with such rapid success, that in the course of two years, he had reduced the power of Abo Abdeli, the eldest son of Albohassen, within the city and plain of Granada. Having occupied the surrounding country with his troops, and built the city of Santa-Fé, he was preparing to invest the Moorish capital, when the besieged prince, more afraid of his subjects than of the enemy, proposed to capitulate, and submitted to the power of Ferdinand. In defiance of the terms expressly stipulated for the protection and toleration of the vanquished, the Moors were finally banished to the sterile regions of their ancestors; and their empire in Spain completely terminated in the year 1492. But for a considerable period after the conquest of Granada, a few scattered bands, who had taken refuge in the mountains, maintained an unavailing struggle with their conquerors, displaying the most heroic spirit in their sufferings, and unshaken constancy to their chiefs. Under the sway of the Mahommedan princes, which comprehends a period of nearly eight centuries, the kingdom of Granada was the seat of opulence, arts, and learning, while the other states of Europe, under the spiritual domination of Rome, were sunk in the deepest mental barbarism. The Omniades in Spain, following the example of Almamon, the seventh caliph of the Abassides, exerted themselves so sedulously in the advancement of knowledge, that they are said to have collected 600,000 volumes, and to have established 70 public libraries in the cities under their dominion. The Arabian writers enumerate, in 1126, 150 authors natives of Cordova, 52 of Almeria, 76 of Murcia, and 53 of Malaga, besides those of Seville, Valencia, and Granada, where the spirit of literature was preserved in full vigour nearly four centuries. In this last mentioned city, where it principally flourished, there were at that time two universities, two royal colleges, and a public library, stored with the productions of the best Greek and Arabic writers. The love of learning was so general in Granada, that, in spite of the prohibitions of Mahomed, it extended to the female sex; and we find recorded the names of the poetess Naschina, the historian Mosada, and the mathematician Leila. Their physicians, though imperfectly acquainted with anatomy, as their religion prohibited all dissections of the human frame, acquired great celebrity. Botany was one of their favourite studies; and they made some progress in the operations of chemistry. They chiefly excelled in the various branches of mathematics, namely, astronomy, arithmetic, geometry, trigonometry, and optics; but they were little acquainted with physics, and, though they were instrumental in preserving many Greek authors, they were as little acquainted as the nations of Christendom at that period, with the classical authors of Greece and Rome. Among the Arabians, in short, in the south of Spain, human genius is said to have produced more prodigies in a few centuries, than it has done in the history of ages in all the rest of the world. All the great modern discoveries, paper, printing, the mariner's compass, glass, gunpowder, &c. are affirmed to have been there anticipated and again forgotten; and in the exercise of fancy and invention they are considered as having far surpassed all former and succeeding ages. Agriculture formed the principal occupation of the Saracens in Granada; and, while it was stimulated by the demands of an extensive population, it was improved by the aids of science. They were particularly attentive to the application of manure, which they preserved in pits, that none of the salts might be lost; and they carried the practice of irrigation to a very great extent. But, as their bigotry forbade the sale of their superfluous grain to the neighbouring nations, they pursued its cultivation no farther than was requisite for their own subsistence; and directed much of their attention to the culture of fruits, which generally formed their principal aliment. To them Spain is indebted for the introduction of an infinite variety of fruits, and of its best horticultural productions, for the sugar-cane also, and the cotton-tree. Their commerce was not less extensive, and the luxuries of India were brought from Alexandria to Malaga at an early period. The silks of India, and the porcelains of China, were soon imitated, and even excelled by the Moors. They were skilled in the manufacture of woollen, cotton, and flax, but, above all, in the art of dyeing of leather. They made some progress in working mines, especially of lead and iron; and their articles of steel, particularly the swords of Granada, were preferred to all others in Spain. In their architectural plans and ornaments, they were deficient in taste; but their joiners and inlayers of wood worked with the utmost nicety; and they painted and gilded their stucco work with singular skill. Upon the banishment of this ingenious people, the arts and sciences departed with them; the magnificence, commerce, and manufactures of Granada rapidly decayed; and the indolence, poverty, and barbarism, which succeeded in their place, continue, in no small degree, to overspread the face of the most highly gifted region in the world.

Granada is beautifully diversified with majestic mountains, extensive plains, and delightful vallies. A chain of mountains, named the Alpuxarres, extends through the province from west to east. The loftiest points of the whole range are those of the Sierra Nevada, near the city of Granada, one of which, called Mulhacen, is 12,762 feet above the level of the sea; and all above 9915 feet are covered with perpetual snow. The mountains towards the south gradually decline in height, till at the Sierra de Gador, near Almeria, where they rise to the elevation of 7800 feet. At this extremity near Macael is the celebrated rock called Filabres, which is four miles in circumference, two thousand feet in height, and which consists of one entire and solid piece of white marble. The secondary mountains are of various kinds; but many are composed of marble of different colours, black, white, red, and flesh colour. About two leagues from Granada, on the banks of the Xenil, is a quarry of green serpentine beautifully veined, and capable of receiving a fine polish. There are many sorts of alabaster in the mountains which environ the city, some of which are as brilliant and transparent as oriental cornelians. There are also quarries of jasper, and a variety of precious stones. In the mountains of this province are several mines of silver, copper, and lead, some of which were formerly worked by the Moors. Gold is found in the sands of the river Darro; but of late the quantity has been small. Mineral waters, both cold and hot springs, are very abundant in the province; but few of them have been analysed: They are chiefly chalybeates, and sulphureous. But one of the most remarkable circumstances in the mountains of Granada is the quantity of bones, of men and other animals, found on their summits, especially at Concud, where there is a hill entirely composed of them, lying under a stratum of limestone.

The climate of Granada is cold in the mountainous districts; extremely hot and sultry in the vallies; but it is tempered in the plains by the coolness of the waters, which are conveyed in all directions. The country is exposed to a number of winds, particularly on the coast; one of which especially, called Solano, is attended with the most pernicious effects. It is a hot wind, which blows from Africa, dries up the plants as soon as it touches them, affects the body with the feelings of strong fever, and throws the mind into a state little better than madness. Murders and assassinations are observed to be most frequent during its prevalence.

In this province agriculture is in a more flourishing state than in any other district in the south of Spain; and the Vega of Granada, already described, is the finest and richest plain in the kingdom. The principal mode employed for aiding the crops is the irrigation of the soil. Streams are conveyed along the upper side of every field by means of embankments, in which sluices are cut, which convey the water into small gutters; and these are allowed to run at short intervals, so as to flood the whole field with ease in the hot season. Great attention is paid to the preservation of manure, which, according to the old Moorish practice, is collected in large pits, well rammed, to prevent leaking; and, when once well rotted, is distributed over the land, in a state almost liquid. It is not applied, however, to the production of corn, but is used in the gardens, the melon grounds, and the mulberry plantations. Yet, without any manure, and by the mere assistance of irrigation, the most abundant crops of grain are raised, especially of wheat, barley, and maize. On land capable of being properly watered, the annual produce of wheat is said to be fifty bushels per acre. Great quantities of rice are cultivated in the lower grounds near the rivers, and subject to floods; and frequently a crop of hemp, or flax, is taken from the land before the rice is sown. But the Spanish farmers pay more attention to the breeding and fattening of cattle, than to the cultivation of grain or fruits. They make no hay; but the grass grows most abundantly in winter, when the cattle are fed in the uplands; and after harvest, which is generally in June, the stubble fields furnish subsistence to the flocks and herds. The flax and hemp are very cheap; and the latter, having a remarkably strong fibre, is thought to make the best sail cloth. There are very extensive plantations of mulberry trees, which are cultivated solely for the sake of the leaves, as the food of the silk worm. The white mulberry, grafted on the wild stock, is considered as the best for that purpose, and as making the worms yield a finer silk than the red or black species: The tops are cut off to increase the quantity of leaves. As much silk is annually raised in the plain of Granada as furnishes employment to 1500 persons. The manufactures in the city alone are calculated to require a supply of 100,000lbs. It is estimated, that 1500 worms produce about one pound of silk; and it is found, that a mulberry tree, of ten years of age, will scarcely supply food for as many of these insects as yield seven pounds. The mountains round the city of Granada are well calculated for vines, but so little attention is paid to their cultivation, that the wine produced from them is of a very inferior kind, and generally acquires a disagreeable taste from the sheep skins with tarred seams in which it is brought from the vineyards; but, in other parts of the province, excellent wines are made, especially the Tierno, Moscatel, and Malaga. The grapes often grow in bunches of eight, ten, and even fourteen pounds weight, and great quantities are dried in the sun for exportation. Olive trees are numerous; but oil is not produced in sufficient quantity for the consumption of the inhabitants. Sugar canes are cultivated in many parts, but especially around Malaga; and are as large and juicy as those of the West Indies.

The commerce of Granada with the other provinces, consists chiefly in exchanging corn, wine, and dried fruits, for oil and silk. Its trade with foreign countries is carried on from the ports of Almeria and Malaga, (see ALMERIA and MALAGA,) and consists in exports of wine, dried fruits, oil, anchovies, lemons, almonds, lead, kali, sumach; and in imports of cloths, ironware, mercery, lace, &c.

The inhabitants of this province, like the Andalusians in general, are considered as the Gascons of Spain, vain, talkative, boastful, and licentious. The women are represented as sufficiently seducing, handsome in their figure, and peculiarly attractive as dancers. The language is mixed with so many Arabic words, and the pronunciation so guttural and vitiated, that a Castilian often finds it difficult to understand the speech of an Andalusian. See the works referred to under the preceding article. (*q*)

GRANADA, NEW, a division of Spanish America, lying between 2° and 8° of North Latitude; is bounded on the north and east by Caraccas and Cumana, on the west by Popayan, and on the south by Peru. It extends in length about 300 miles, and nearly as much in breadth. It is so far elevated above the level of the sea, that, though approaching almost to the equator, its climate is remarkably temperate. Its vales and level districts are not inferior in fertility to the richest spots of America. Its mountainous tracts abound in mines of gold, silver, lead, copper, and in precious stones of various kinds. Its forests afford a variety of excellent timber, adapted particularly for ship-building. Its principal towns are Bogota or Santa Fé de Bogota, the seat of government, and the see of an archbishop, situated nearly in 4° North Latitude, and containing 40,000 inhabitants; Flonda, a pleasant little town on the river Magdalena, about 60 miles north-west of the capital, the principal port for the commerce of the interior provinces, and containing about 10,000 inhabitants; Merida, a considerable manufacturing town in 8° 11′ north latitude, situated in a well-watered valley, about 20 leagues south of Lake Maracaiba, and containing 11,000 inhabitants; Neyva, 107 miles south-west of the capital; Maraquita, 59 miles north-west; St. Miguel, 94 miles north-east; Caguan, south of Neyva and Tunia in 5½° North Latitude; all small settlements, rather in a declining state. There are likewise several missionary stations, especially towards the south of the province, called Los Llanos, and several villages of the Indians. Antioquia, perhaps rather a separate province, is also generally comprehended in that of New Granada. It is situated towards the west, bounded by Carthagena on the north, by Popayan on the south, and on the west by Choca. It is mountainous, and abounding in mines; temperate, well watered, and rich in pastures. Its capital, of the same name, in the valley of Nori, is situated in 7° 14′ North Latitude.

A few manufactures of cotton cloths, carpets, counterpanes, and woollens, chiefly for the purposes of internal consumption, are carried on in the province. Several of its native productions, especially chocolate, tobacco, and cotton, all of excellent quality, might be collected in great abundance for exportation; and the river Magdalena, which runs through the province into the Atlantic, and is navigable as far as Florida, 160 leagues from its mouth, affords a commodious outlet to the European markets. But agriculture and trade are said to have greatly declined of late years in the province; and its present unsettled state, struggling for independence of the mother country, though likely to issue at length in its prosperity, must obviously be extremely unfavourable to every kind of cultivation or commerce. Its chief support is derived from the produce of its gold mines. These indeed can scarcely be called mines, as the metal is not generally procured by digging into the earth, but is mingled with the soil near the surface, from which it is separated by repeated washings. This work is commonly performed by Negro slaves, who cannot bear the chill air of the mines, but are more able than the Indians to support the labours of the field. In some districts, the metal is found in large grains; and on some spots, particularly near Pamplona, single labourers have collected in one day a quantity equivalent to 1000 pesos. One of the governors of Santa Fé procured a mass of pure gold estimated to be worth 740*l.*, which was deposited in the royal cabinet of Madrid as the finest and largest specimen ever found in the New World.

Granada, or Santa Fé, as it is sometimes called, gives name to an extensive viceroyalty, which is sometimes confounded with the province, properly so denominated. This kingdom of New Granada was originally established in 1547, and was governed by a royal audience, with a captain-general as president. In 1718, it was formed into a viceroyalty, which was suppressed in 1724, and finally restored in 1740. It comprises the provinces of Carthagena, Panama, Santa Martha, Maracaibo, Porto Bello, Antiognia, Choca, Granada Proper, Veragua, Mariquita, Rio de la Hacha, Giron, Neyva, and the Llanos, which form the northern division, under the jurisdiction of the royal audience at Santa Fé; and the southern districts, Jaen de Bracamoros, Loja, Cuenza, Macas, Riobamba, Popayan, Quito, Guayaquil, &c. which are under the jurisdiction of a governor and royal audience at Quito, who are subordinate to the viceroy of New Granada. This extensive territory, when first subjected to Spain in 1536, was more populous, and its inhabitants more civilized, than any other portion of America; but the amount of its whole population is now calculated by M. Humboldt only at 1,800,000. Nothing is wanting for its prosperity, but the revival of industry and commerce; and nothing prevents it from enjoying these benefits, but the impolitic restrictions and oppressive system of its European rulers. See Robertson's *History of America*, vol. iii.; Playfair's *Geography*, vol. vi.; Pinkerton's *Geography*, vol. iii.; and Humbolt's *Account of New Spain*. (*q*)

GRANGE, JOSEPH-LOUIS LA,* a celebrated mathematician and natural philosopher, was born at Turin, on the 25th of November, 1736. He was the son of Joseph Louis la Grange, treasurer of war, and of Marie-Therese Gros, only daughter of a rich physician of Cambiano.

His father was rich, and had made an advantageous marriage: but was ruined by hazardous undertakings. Let us not, however, lament the situation of M. la Grange. He himself viewed it as the first cause of all the good fortune that afterwards befel him. "Had I been in possession of a fortune," said he, "I should not probably have studied mathematics." In what other situation would he have found advantages that could enter into comparison with those of a tranquil and studious life, with that splendid series of discoveries in a branch of science considered as the most difficult, and with that personal respectability which was continually increasing to the very last period of his life?

His taste for mathematics did not appear at first. He was passionately devoted to Cicero and Virgil, before he could read Archimedes and Newton. He then became an enthusiastic admirer of the geometry of the ancients, which he preferred to the modern analysis. A memoir which the celebrated Halley had composed long before, to demonstrate the superiority of the analytic method, had the glory of converting him, and of teaching him his true destiny. He devoted himself to this new study with the same success that he had in the synthesis, and which was so decided, that at the age of 16 he was professor of mathematics in the Royal Military School. The extreme youth of a professor is a great advantage to him when he has shown

* This excellent life of La Grange is taken, with a few slight abridgments, from the eloge of the Chevalier Delambre, with whose kind permission it is here published. As we have not been able to get a copy of the original eloge, we have been obliged to make use of the translation in Dr Thomson's *Annals of Philosophy*, vol. iii. ED.

extraordinary abilities, and when his pupils are no longer children. All the pupils of M. la Grange were older than himself, and were not the less attentive to his lectures on that account. He distinguished some of them, whom he made his friends.

From this association sprung the academy of Turin, which in 1759 published a first volume, entitled Acts of a private Society. We see there the young La Grange directing the philosophical researches of the physician Cigna, and the labours of the Chevalier de Saluces. He furnished to Foncenex the analytical part of his memoirs, leaving to him the task of developing the reasoning upon which the formulæ depended. In these memoirs, which do not bear his name, we observe that purely analytical method, which afterwards characterised his great productions. He had discovered a new theory of the lever. It constitutes the third part of a memoir, which was very successful. Foncenex, in recompense, was placed at the head of the Marine, which the king of Sardinia formed at that time. The two first parts have the same style, and seem written by the same person. Do they likewise belong to La Grange? He never expressly laid claim to them; but what may throw some light on the real author is, that Foncenex soon ceased to enrich the volumes of the new academy, and that Montucla, ignorant of what La Grange revealed to us during the latter part of his life, is astonished that Foncenex interrupted those researches which might have given him a great reputation.

M. la Grange, while he abandoned to his friend insulated theorems, published at the same time, under his own name, theories which he promised to develope further. Thus after having given new formulæ of the *maximum* and *minimum* in all cases, after having shown the insufficiency of the known methods, he announces that he will treat this subject, which he considered as important, in a work which he was preparing, in which, would be deduced from the same principles all the mechanical properties of bodies, whether solid or fluid. Thus at the age of 23 he had laid the foundation of the great works, which have commanded the admiration of philosophers.

In the same volume he reduces under the differential calculus the theory of recurrent series and the doctrine of chances; which before that time had only been treated by indirect methods. He established them upon more natural and general principles.

Newton had undertaken to submit the motions of fluids to calculation. He had made researches on the propagation of sound; but his principles were insufficient, and his suppositions inconsistent with each other. La Grange demonstrates this. He founds his new researches on the known laws of dynamics, and, by considering only in the air the particles which are in a straight line, he reduces the problem to that of vibrating cords, respecting which the greatest mathematicians differed in opinion. He shows that their calculations are insufficient to decide the question. He undertakes a general solution by an analysis equally new and interesting, which enables him to resolve at once an indefinite number of equations, and which embraces even discontinued functions. He establishes on more solid grounds the theory of the mixture of simple and regular vibrations of Daniel Bernoulli. He shows the limits within which this theory is exact, and beyond which it becomes faulty. Then he comes to the construction given by Euler, a construction true in itself, although its first author had arrived at it by calculations which were not quite rigorous. He answers the objections of D'Alembert. He demonstrates that whatever figure is given to the cord, the duration of the oscillations is always the same: a truth derived from experiment, which D'Alembert considered as very difficult, if not impossible, to demonstrate. He passes to the propagation of sound, treats of simple and compound echos, of the mixture of sounds, of the possibility of their spreading in the same space without interfering with each other. He demonstrates rigorously the generation of harmonious sounds. Finally, he announces that his intention is to destroy the prejudices of those who still doubt whether the mathematics can ever throw a real light upon physics.

We have given this long account of that memoir, because it is the first by which M. la Grange became known. If the analytical reasoning in it be of the most transcendent kind, the object at least has something sensible. He recals names and facts which are well known to most people. What is surprising is, that such a first essay should be the production of a young man, who took possession of a subject treated by Newton, Taylor, Bernoulli, D'Alembert, and Euler. He appears all at once in the midst of these great mathematicians as their equal, as a judge, who, in order to put an end to a difficult dispute, points out how far each of them is in the right, and how far they have deceived themselves; determines the dispute between them, corrects their errors, and gives them the true solution, which they had perceived without knowing it to be so.

Euler saw the merit of the new method, and took it for the object of his profoundest meditations. D'Alembert did not yield the point in dispute. In his private letters, as well as in his printed memoirs, he proposed numerous objections, to which La Grange afterwards answered. But these objections may give rise to this question: How comes it that, in a science in which every one admits the merit of exactness, geniuses of the first order take different sides, and continue to dispute for a long time? The reason is, that in problems of this kind, the solutions of which cannot be subjected to the proof of experiment, besides the part of the calculation which is subjected to rigorous laws, and respecting which it is not possible to entertain two opinions, there is always a metaphysical part which leaves doubt and obscurity. It is because in the calculations themselves, mathematicians are often content with pointing out the way in which the demonstration may be made; they suppress the developments, which are not always so superfluous as they think. The care of filling up these blanks would require a labour which the author alone would have the courage to accomplish. Even he himself, drawn on by his subject and by the habits which he has acquired, allows himself to leap over the intermediate ideas. He defines his definitive equation, instead of arriving at it step by step with an attention that would prevent every mistake. Hence it happens that more timid calculators sometimes point out mistakes in the calculations of an Euler, a D'Alembert, a La Grange. Hence it happens that men of very great genius do not at first agree, from not having studied each other with sufficient attention to understand each other's meaning.

The first answer of Euler was to make La Grange an associate of the Berlin academy. When he announced to him this nomination on the 20th of October, 1759, he said, "Your solution of the problem of isoperimeters leaves nothing to desire; and I am happy that this subject, with which I was almost alone occupied since the first attempts, has been carried by you to the highest degree of perfection. The importance of the matter has induced me to draw up, with your assistance, an analytical solution of it. But I shall not publish it till you yourself have published the sequel of your researches, that I may not deprive you of any part of the glory which is your due."

If these delicate proceedings, and the testimonies of the highest esteem, were very flattering to a young man of 24 years of age, they do no less honour to the great man, who at that time swayed the sceptre of mathematics, and who thus accurately estimated the merit of a work that announced to him a successor.

But these praises are to be found in a letter. It may be supposed that the great and good Euler has indulged in some of those exaggerations which the epistolary style permits. Let us see then how he has expressed himself in the dissertation which his letter announced. It begins as follows:

"After having fatigued myself for a long time and to no purpose, in endeavouring to find this integral, what was my astonishment when I learnt that in the Turin Memoirs the problem was resolved with as much facility as felicity! This fine discovery produced in me so much the more admiration, as it is very different from the methods which I had given, and far surpasses them all in simplicity."

It is thus that Euler begins the memoir, in which he explains with his usual clearness the foundation of the method of his young rival, and the theory of the new calculus, which he called the *calculus of variations*.

To make the motives of this admiration which Euler bestowed with so much frankness better understood, it will not be useless to go back to the origin of the researches of La Grange, such as he stated them himself two days before his death.

The first attempts to determine the *maximum* and *minimum* in all indefinite integral formulæ, were made upon the occasion of the curve of swiftest descent, and the isoperimeters of Bernoulli. Euler had brought them to a general method, in an original work, in which the profoundest knowledge of the calculus is conspicuous. But however ingenious his method was, it had not all the simplicity which one would wish to see in a work of pure analysis. The author admitted this himself. He allowed the necessity of a demonstration independent of geometry. He appeared to doubt the resources of analysis, and terminated his work by saying, "If my principle be not sufficiently demonstrated, yet as it is conformable to truth, I have no doubt that, by means of a rigid metaphysical explanation, it may be put in the clearest light, and I leave that task to the metaphysicians."

This appeal, to which the metaphysicians paid no attention, was listened to by La Grange, and excited his emulation. In a short time the young man found the solution of which Euler had despaired. *He found it by analysis.* And in giving an account of the way in which he had been led to that discovery, he said expressly, and as it were in answer to Euler's doubt, that he regarded it not as a metaphysical principle, but as a necessary result of the laws of mechanics, as a simple corollary from a more general law, which he afterwards made the foundation of his *Mechanique Analytique.* (See that work, page 189 of the first edition.)

This noble emulation, which excited him to triumph over difficulties considered as insurmountable, and to rectify or complete theories remaining imperfect, appears to have always directed M. la Grange in the choice of his subjects.

D'Alembert had considered it as impossible to subject to calculation the motions of a fluid inclosed in a vessel, unless this vessel had a certain figure. La Grange demonstrates the contrary; except in the case when the fluid divides itself into different masses. But even then we may determine the places where the fluid divides itself into different portions, and ascertain the motion of each as if it were alone.

D'Alembert had thought that in a fluid mass, such as the earth may have been at its origin, it was not necessary for the different beds to be on a level. La Grange shows that the equations of D'Alembert are themselves equations of beds on a level.

In combating D'Alembert with all the delicacy due to a mathematician of his rank, he often employs very beautiful theorems, for which he was indebted to his adversary. D'Alembert on his side added to the researches of La Grange. "Your problem appeared to me so beautiful," says he in a lettter to La Grange, "that I have sought for another solution of it. I have found a simpler method of arriving at your elegant formula." These examples, which it would be easy to multiply, prove with what politeness these celebrated rivals corresponded, who, opposing each other without intermission, whether conquerors or conquered, constantly found in their discussion reasons for esteeming each other more, and furnished to their antagonist occasions which might lead them to new triumphs.

The academy of sciences of Paris had proposed, as the subject of a prize, the theory of the libration of the moon. That is to say, they demanded the cause why the moon, in revolving round the earth, always turns the same face to it, some variations excepted, observed by astronomers, and of which Cassini had first explained the phenomena. The point was to calculate all the phenomena, and to deduce them from the principle of universal gravitation. Such a subject was an appeal to the genius of La Grange, an opportunity furnished to apply his analytical principles and discoveries. The attempt of D'Alembert was not disappointed. The memoir of La Grange is one of his finest pieces. We see in it the first development of his ideas, and the germ of his *Mecanique Analytique.* D'Alembert wrote to him: "I have read with as much pleasure as advantage your excellent paper on the Libration, so worthy of the prize which it obtained."

This success encouraged the academy to propose, as a prize, the theory of the satellites of Jupiter. Euler, Clairaut, and D'Alembert had employed themselves about the problem of three bodies, as connected with the lunar motions. Bailly then applied the theory of Clairaut to the problem of the satellites, and it had led him to very interesting results. But this theory was insufficient. The earth has only one moon, while Jupiter has four, which ought continually to act upon each other, and alter their positions in their revolutions. The problem was that of six bodies. La Grange attacked the difficulty and overcame it, demonstrated the cause of the inequalities observed by astronomers, and pointed out some others too feeble to be ascertained by observations. The shortness of the time allowed, and the immensity of the calculations, both analytical and numerical, did not permit him to exhaust the subject entirely in a first memoir. He was sensible of this himself, and promised further results, which his other labours always prevented him from giving. Twenty-four years after, M. La Place took up that difficult theory, and made important discoveries in it, which completed it, and put it in the power of astronomers to banish empiricism from their tables.

About the same time a problem of quite a different kind attracted the attention of M. la Grange. Fermat, one of the greatest mathematicians of his time, had left very remarkable theorems respecting the properties of numbers, which he probably discovered by induction. He had promised the demonstrations of them; but at his death no trace of them could be found. Whether he had suppressed them as insufficient, or from some other cause, cannot now be ascertained. These theorems perhaps may appear more curious than useful. But it is well known that difficulty constitutes a strong attraction for all men, especially for mathematicians. Without such a motive would they have attached so much importance to the problems of the brachystrochonon, of the isoperimeters, and of the orthogonal trajectories? Certainly not. They wished to create the science of calculation, and to perfect methods which could not fail some day of finding useful applications. With this view, they attached themselves to the first question which required new resources. The system of the world discovered by Newton was a most fortunate event for them. Never could the transcendant calculus find a subject more worthy or more rich. Whatever progress is made in it, the first discoverer will always retain his rank. Accordingly, M. la Grange, who cites him often as the greatest genius that ever existed, adds also, "and the most fortunate. We do not find every day a system of the world to establish." It has required 100 years of labours and discoveries to raise the edifice of which Newton laid the foundation. But every thing is ascribed to him, and we suppose him to have traversed the whole country upon which he merely entered.

Many mathematicians doubtless employed themselves on the theorems of Fermat; but none had been successful. Euler alone had penetrated into that difficult road in which M. Legendre and M. Gauss afterwards signalized themselves. M. la Grange, in demonstrating or rectifying some opinions of Euler, resolved a problem which appears to be the key of all the others; and from which he deduced a useful result; namely, the complete resolution of equations of the second degree, with two indeterminates, which must be whole numbers.

This memoir, printed like the preceding, among those of the Turin Academy, is notwithstanding dated B rlin, the 20th September 1768. This date points out to us one of the few events which render the life of La Grange not entirely a detail of his writings.

His stay at Turin was not agreeable to him. He saw no person there who cultivated the mathematics with success. He was impatient to see the philosophers of Paris, with whom he corresponded. M. de Caraccioli, with whom he lived in the greatest intimacy, was appointed ambassador to London, and was to pass through Paris on his way, where he intended to spend some time. He proposed this journey to M. la Grange, who consented to it with joy, and who was received as he had a right to expect by D'Alembert, Clairaut, Condorcet, Fontaine, Nollet, Marie, and the other philosophers. Falling dangerously ill after a dinner in the Italian style given him by Nollet, he was not able to accompany his friend to London, who had received sudden orders to repair to his post, and who was obliged to leave him in a furnished lodging, under the care of a confidential person charged to provide every thing.

This incident changed his projects. He thought only of returning to Turin. He devoted himself to the mathematics with new ardour, when he understood that the Academy of Berlin was threatened with the loss of Euler, who thought of returning to Petersburgh. D'Alembert speaks of this project of Euler, in a letter to Voltaire, dated the 3d March 1766: "I shall be sorry for it," says he; "he is a man by no means amusing, but a very great mathematician." It was of little consequence to D'Alembert, whether this man, *by no means amusing*, went seven degrees nearer the pole. He could read the works of the great mathematician as well in the Petersburgh Memoirs as in those of Berlin. What troubled D'Alembert was the fear of seeing himself called upon to fill his place, and the difficulty of giving an answer to offers which he was determined not to accept. Frederick in fact offered him again the place of president of his Academy, which he had kept in reserve for him ever since the death of Maupertuis. D'Alembert suggested the idea of putting La Grange in the place of Euler; and, if we believe the author of the *Secret History of the Court of Berlin*, (vol. ii. p. 414,) Euler had already pointed out La Grange as the only man capable of filling his place. In fact, it was natural that Euler, who wished to obtain permission to leave Berlin, and D'Alembert, who wanted a pretext not to go there, should both of them, without any communication, have cast their eyes on the man who was best fitted to maintain the eclat, which the labours of Euler had thrown round the Berlin Academy.

La Grange was pitched upon. He received a pension of 1500 Prussian crowns, about 250*l*., with the title of Director of the Academy for the Physico-mathematical Sciences. We may be surprised that Euler and La Grange, put successively in the place of Maupertuis, received only the half of his salary, which the king offered entire to D'Alembert. The reason is, that this prince, who at his leisure hours cultivated poetry and the arts, had no idea of the sciences, though he considered himself obliged to protect them as a king. He had very little respect for the mathematics, against which he wrote three pages in verse, and sent them to D'Alembert himself, who deferred writing an answer till the termination of the siege of Schweidnitz; because he thought it would be too much to have both Austria and the mathematics on his hands at once. Notwithstanding the prodigious reputation of Euler, we see, from the king's correspondence with Voltaire, that he gave him no other appellation than his *narrow-minded geometer, whose ears were not capable of feeling the delicacy of poetry*. To which Voltaire replies: *We are a small number of adepts who know one another: the rest are profane.* We see that Voltaire, who had written so well in praise of Newton, endeavours in this place to flatter Frederick. He enters out of complaisance into the ideas of this prince, who wished to put at the head of his academy, a man who had at least some pretensions to literature. Fearing that a mathematician would not take sufficient interest in the direction of literary labours, and that a man of literature would have been still worse placed at the head of a society composed in part of philosophers, of whose language he was ignorant; on that account he divided the situation, and put two persons in it, that it might be completely filled.

M. la Grange took possession of his situation on the 6th of November 1766. He was well received by the king; but soon perceived that the Germans do not like to see foreigners occupy situations in their country. He applied to the study of their language. He devoted himself entirely to mathematics, and did not find himself in the way of any person, because he demanded nothing, and he soon obliged the Germans to give him their esteem. "The king," said he himself, "treated me well; I thought that he preferred me to Euler, who was something of a devotee, while I took no part in the disputes about worship, and did not contradict the opinion of any one." This prudent reserve, if it deprived him of the advantages of an honourable familiarity, which would have been attended with some inconveniences, left him the whole of his time for mathematical labours, which hitherto had brought him nothing but compliments the most flattering and the most unanimous. This concert of praises was only once interrupted during the whole of his life.

A French mathematician, who to much sagacity united a still greater degree of selfishness, and scarcely gave himself the trouble to study the works of others, accused

M. la Grange of *having gone astray in the new route that he had traced, from not having well understood the theory of it.* He reproached him with *having deceived himself in his assertions and calculations.* La Grange in reply expresses some astonishment at these harsh expressions, to which he was so little accustomed. He expected at least to have seen them founded on some reasons either good or bad; but he discovered nothing of the kind. He shews that the solution proposed by Fontaine was incomplete and illusory in certain respects. Fontaine had boasted that he had taught mathematicians the conditions which render possible the integration of differential equations with three variables. La Grange shewed him, by several citations, that these conditions were known to mathematicians long before Fontaine was capable of teaching them. He does not deny that Fontaine discovered these theorems himself; "at least I am persuaded," says he, "that he was as capable of finding them as any person whatever."

It was with this delicacy and moderation that he answered the aggressor. Condorcet, in his *eloge* of Fontaine, is obliged to avow that, on this occasion, his friend deviated from that politeness which ought never to be dispensed with, but which perhaps he thought less necessary with illustrious adversaries, whose glory did not stand in need of these little delicacies. Every one can estimate the value of that apology, especially when applied to a man who, by his own acknowledgment, studied the vanity of others, that he might have an opportunity of wounding it. We must at least acknowledge, that he, who saw himself attacked in that manner when he was in the right, and who knew how to maintain politeness with an adversary who had himself dispensed with it, acquired a double advantage over him, besides victoriously repelling his imprudent attack.

It will not be expected that we should follow M. la Grange in the important researches with which he filled the Berlin Memoirs; and even some volumes of the Memoirs of the Turin Academy, which was indebted to him for its existence. All the space that can be devoted to this biographical account would not be sufficient even to convey an imperfect idea of the immense series of his labours, which have given so much value to the Memoirs of the Berlin Academy, while it had the inestimable advantage of being directed by M. la Grange. Some of these Memoirs are of such extent and importance, that they might pass for a great separate work, yet they constitute a part only of what these twenty years enabled him to produce. He had composed his *Mecanique Analytique*, but he wanted to have it printed at Paris, where he expected that his formulæ would be given with more care and fidelity. On the other hand, it was running too great a risk to intrust the manuscript into the hands of a traveller, who might not be aware of the whole of its value. M. la Grange made a copy of it, which M. Duchatelet undertook to deliver to the Abbé Marie, with whom he was intimately connected. Marie fulfilled with honour the confidence placed in him. His first care was to find a bookseller who would undertake to publish it; and, what it will be difficult to believe at this time, he could not find one. The newer the methods in it were, and the more sublime the theory, the fewer readers would be found capable of appreciating it; hence, without entertaining any doubts of the merit of the work, the booksellers were excusable in hesitating to print a book, the sale of which would probably be confined to a small number of mathematicians, disseminated through Europe. Desain, who was the most enterprising of all those to whom application was made, would not undertake to publish it, till Marie entered into a formal engagement to take all the copies of the edition which were not sold by a given time. To this first service, Marie added another, of which M. la Grange was not less sensible; he procured him an editor worthy of superintending the publication of such a work. M. Legendre devoted the whole of his time to the troublesome task of correcting the press, and was repaid by the sentiment of veneration for the author with which he was penetrated; and by the thanks which he received from him in a letter which I have had in my possession, and which M. la Grange had filled with expressions of his esteem and his gratitude.

The book was not yet published when the author came to settle in Paris. Several causes determined him to take this step; but we must not give credit to all that have been stated. The death of Frederick had occasioned great changes in Prussia, and still greater were to be apprehended. Philosophers were no longer so much respected as formerly. It was natural for M. la Grange again to feel that desire which had formerly conducted him to Paris. These causes, together with the publication of the *Mecanique Analytique*, were sufficient. It is not necessary to add other causes, which several publications that made their appearance in Germany, and particularly the anonymous historian of the court of Berlin, have noticed. We never, during a residence of 25 years in France, heard M. la Grange prefer the slightest complaint against the minister, who is accused in that publication of having disgusted him by a treatment full of haughtiness and contempt, which, out of respect for himself, it was impossible for M. la Grange to overlook. We might suspect that M. la Grange had sufficient generosity to forget or pardon bad treatment, which he punished in the only way worthy of himself, by leaving the country where his merit was overlooked; but when he was directly questioned on that subject by a member of the Institute, (M. Burckhardt,) he only gave negative answers, and assigned no other motives than the misfortunes which it was thought were about to fall upon Prussia. M. de Hertzberg was dead, and M. de la Grange, a senator and count of the French empire, could have no interest in concealing the truth. Hence we must consider his own statement as affording the only true reasons.

The historian, therefore, whom we have quoted, has been ill informed. But the spirit of calumny and satire, which has so justly rendered his work suspected, ought not to prevent us from extracting from it the lines, in which he explains, with that energy which is peculiarly his own, his opinion, which is that of all Europe, when he does justice to M. la Grange.

"I think," says he, (*Hist. Sec. de la Cour de Berlin*, 1789, tom. ii. page 173) "that there is at this moment an acquisition worthy of the king of France, the illustrious La Grange, the greatest mathematician who has appeared since Newton, and who in every point of view is the man that has the most astonished me;—La Grange, the wisest, and perhaps the only practical philosopher that ever existed, meritorious by his undisturbable wisdom, his manners, his conduct; the object of the most tender respect of the small number of men with whom he associates:—La Grange is misunderstood; every thing leads him to leave a country where nothing can excuse the crime of being a foreigner, and where in fact he is merely tolerated. Prince Cardito de Laffredo, Neapolitan minister at Copenhagen, offered him the most flattering conditions on the part of his sovereign. The Grand Duke, the king of Sardinia, invited him eagerly; but all their proposals would be easily obliterated by ours. I am very eager to see this proposal made, because I consider it as noble, and because I tenderly love the man who is the object of it. I have induced M. la

Grange not to accept immediately the proposals made to him, and to wait till he receives ours."

The author whom we quote appears to fear the opposition of M. Breteuil; but, according to M. la Grange himself, it was the Abbé Marie who proposed it to M. Breteuil, who on all occasions anticipated the desires of the Academy of Sciences, presented the demand to Louis XVI. and induced him to agree to it.

The successor of Fredorick, although he did not much interest himself in the sciences, made some difficulty in allowing a philosopher to depart whom his prodecessor had invited, and whom he honoured with his particular esteem. After some delay, M. la Grange obtained liberty to depart. It was stipulated that he should still give some memoirs to the Berlin Academy. The volumes of 1792, 1793, and 1803, show that he faithfully kept his promise.

It was in 1787, that M. la Grange came to Paris to take his seat in the Academy of Sciences, of which he had been a foreign member for fifteen years. To give him the right of voting in all their deliberations, this title was changed into that of *veteran pensionary*. His new associates shewed themselves happy and proud in possessing him. The queen treated him with regard, and considered him as a German. He had been recommended to her from Vienna. He obtained a lodging in the Louvre, where he lived happy till the Revolution.

The satisfaction which he enjoyed did not show itself outwardly. Always affable and kind when interrogated, he himself spoke but little, and appeared absent and melancholy. Often in companies which must have been suitable to his taste, among the most distinguished men of all countries who met at the house of the illustrious Lavoisier, I have seen him dreaming, as it were, with his head against a window, where however nothing attracted his attention. He remained a stranger to what was passing around him. He acknowledged himself that his enthusiasm was gone, that he had lost his taste for mathematics. When informed that a mathematician was employed at such a task, "so much the better," he would say; "I had begun it, now it will be unnecessary for me to finish it." But he merely changed the object of his studies. Metaphysics, the history of human nature, that of different religions, the general theory of languages, medicine, botany, divided his leisure hours. When the conversation turned upon subjects with which it was supposed he was unacquainted, we were struck by an unexpected observation, a fine thought, a profound view, which excited long reflections. Surrounded by chemists who were reforming the theory and even the language of the science, he made himself acquainted with their discoveries, which gave to facts formerly isolated that connection which distinguishes the different parts of mathematics. He undertook to make himself acquainted with this branch of knowledge, which formerly appeared to him so obscure, but which he found on trial *as easy as algebra*. People have been surprised at this comparison, and have thought that it could come from no one else than La Grange. It appears to us as simple as just; but it must be taken in its true sense. Algebra, which presents so many insoluble problems, so many difficulties against which La Grange himself struggled in vain, could not in that sense appear to him an easy study. But he compares the new elements of chemistry with those of algebra. They constituted a body, they were intelligible, they offered more certainty; they resembled algebra, which in the part of it that is complete presents nothing difficult to concieve, no truth to which we may not arrive by the most palpable reasoning. The commencement of the science of chemistry appeared to him to offer the same advantages, perhaps with somewhat less stability and certainty; but, like algebra, it has no doubt also its difficulties, its paradoxes, which will require, to explain them, much sagacity, reflection, and time. It has likewise its problems which never will be resolved.

In this philosophic repose he continued till the Revolution, without adding any thing to his mathematical discoveries, or even opening his *Mecanique Analytique*, which had been published for two years.

The Revolution gave philosophers an opportunity of making a great and difficult innovation; the establishment of a system of weights and measures founded on nature, and perfectly analogous to our scale of numbers. La Grange was one of the commissioners whom the Academy charged with that task. He was one of its keenest promoters. He wished to see the decimal system in all its purity. He was provoked at the complaisance of Borda, who got quarters of the *metre* made. He thought the objection of little importance which was drawn against the system from the small number of divisors that its base afforded. He regretted that it was not a prime number, as 11, which would have given the same denominator to all the fractions. This idea perhaps will be regarded as one of those exaggerations, which are hazarded by men of the best understandings, in the heat of dispute. But he mentioned the number 11 merely to get rid of the number 12, which more intrepid innovators would have wished to substitute, in place of the number 10, that constitutes the base of the whole of our numeration.

When the Academy was suppressed, the commission charged with the establishment of the new system was retained for a time. Three months had scarcely elapsed when, in order to purify that commission, the names of Lavoisier, Borda, La Place, Coulomb, Brisson, and Delambre, were struck out. La Grange was retained. In quality of president, he informed me, in a long letter full of kindness, that I should recieve official information of my removal. As soon as he saw me on my return to Paris, he expressed to me his regret at the dismissal of so many associates. "I do not know," said he, "why they have retained me." But unless the suppression had been total, it could scarcely have extended to him. The more losses the commission had sustained, of the more importance was it not to deprive it of the consideration attached to the name of La Grange. Besides, he was known to be wholly devoted to the sciences; he had no place either in the civil department or the administration. The moderation of his character had prevented him from expressing what he could not but think in secret; but I shall never forget the conversation which I had with him at that period. It was the day after the atrocious and absurd sentence, contrary to every thing like justice, had thrown all lovers of the sciences into mourning, by cutting off the most illustrious philosopher in Europe. "It has cost them but a moment," said he, "to cut off that head, and a hundred years perhaps will not be sufficient to produce another like it." Some months before we had had a similar conversation in the cabinet of Lavoisier, on account of the death of the unfortunate Bailly. We lamented together the dreadful consequences of the dangerous experiment which the French had attempted. All these chimerical projects of amelioration appeared to him very equivocal proofs of the greatness of the human mind. "If you wish to see it truly great," added he, "enter into the cabinet of Newton, employed in decomposing light, or in explaining the system of the world."

Already for some time he had regretted not having listened to the advice of his friends, who at the commencement of our troubles had recommended him to seek an asylum, which it would have been so easy for him to find. As long as the revolution seemed only to threaten the pension which he enjoyed in France, he had neglected that consideration, out of curiosity to be upon the spot of one of those great convulsions which it is always more prudent to observe at a distance. "It was your own choice," said he several times to himself, when he entrusted me with his regret. It was to no purpose that a special decree of the Constituent Assembly had ensured the payment of his pension. The decree was of no value, because the depreciation of the paper currency was sufficient to render it illusory. He had been named member of the *Board of Consultation*, appointed to examine and reward useful inventions. He had been appointed one of the administrators of the Mint. This commission offered him few objects to fix his attention, and could in no degree remove his apprehensions. It was again proposed to draw him to Berlin, and to restore him to his former situation. He had agreed to the proposal. Herault de Sechelles, to whom he had applied for a passport, offered him, for the greater security, a mission to Prussia. Madame La Grange would not consent to quit her country. This repugnance, which at that time he considered as a misfortune, was to him a source of fortune and of new glory.

The Normal School, of which he was named professor, but which had only an ephemeral existence, scarcely gave him time to explain his ideas respecting the foundation of arithmetic and algebra, and their application to geometry.

The Polytechnic School, the result of a happier idea, had likewise a more durable success: and among the best effects which it produced, we may place that of having restored La Grange to Analysis. It was there that he had an opportunity of developing those ideas, the germ of which was to be found in two memoirs that he had published in 1772, and the object of which was to explain the true metaphysics of the differential and integral calculus. To render these happy developements more easily understood, the professor associated himself with his pupils. It was then that he composed his Analytical Functions, and his Lectures on that Calculus, of which he published several editions.

It was then likewise that he published his treatise on the numerical solution of equations, with notes on several points of the theory of algebraic equations.

It is said that Archimedes, whose great reputation, at least with the historians, is founded upon the machines of all kinds, by means of which he retarded the taking of Syracuse, despised these mechanical inventions, on which he wrote nothing, and placed importance only in his works of pure theory. We may sometimes conceive, that the great mathematicians of our age entertained the same sentiments with Archimedes. They consider a problem as solved when it presents no analytical difficulty, when nothing remains to be done but differentiations, substitutions and reductions, operations which require merely patience, and a certain dexterity derived from practice. Satisfied with having removed all the real difficulties, they concern themselves perhaps too little with the embarrassments which they leave to the calculator, and with the long labour necessary in order to make use of their formula, even after it has been suitably reduced. M. la Grange had more than once attempted to abridge the usual calculations.

The general resolution of algebraic equations is subject to difficulties which are considered as insurmountable; but in practice every determinate problem brings us to an equation, all the co-efficients of which are given in numbers. It would be sufficient, therefore, to have a sure method of finding all the roots of such an equation which is called *numerical*. This was the object which M. la Grange proposed to himself. He analyses all the known methods, and shews their uncertainty and insufficiency. He reduces the problem to the determination of a quantity smaller than the smallest difference between the roots. This is something. We cannot too much admire the analytical skill displayed throughout the whole work. But notwithstanding all the resources of the genius of M. la Grange, we cannot conceal that the labour of his method is exceedingly great, and calculators will doubtless continue to prefer methods less direct indeed, but more expeditious. The author resumed this subject no less than four times. It is to be feared, that a commodious and general solution will never be discovered, or at least it must be sought for by other means. The author seems to have acknowledged this himself, as he recommends the method of M. Budan as the most convenient and elegant for resolving equations whose roots are all real.

The desire of multiplying useful applications induced him to undertake a new edition of the *Mecanique Analytique*. His project was to develope the most useful parts of it. He laboured at it with all the ardour and intellectual power which he could have applied at any period of his life. But this application occasioned a degree of fatigue, which threw him into a fainting fit. He was found in that state by Madame La Grange. His head in falling had struck against the corner of a table, and this shock had not restored him to his senses. This was a warning to take more care of himself. He thought so at first; but he was too anxious to finish his work. The first volume had appeared some time before his death. It had been followed by a new edition of his *Fonctions Analytiques*. So much labour exhausted him. Towards the end of March a fever came on, he lost his appetite, his sleep was uneasy, and his waking was accompanied by alarming swoonings. He perceived his danger; but, preserving his undisturbable serenity, he studied what passed within him, and, as if he were assisting at a great and uncommon experiment, he bestowed all his attention on it. His remarks have not been lost. Friendship conducted to his house on the 8th of April, in the morning, MM. Lacepede, Monge, and Chaptal, who took care to write down the principal points of a conversation which was his last. (We have scrupulously followed these notes, and the passages under inverted commas are faithfully copied from the manuscript of M. Chaptal.)

"He received them with tenderness and cordiality. I was very ill, my friends, (said he,) the day before yesterday; I perceived myself dying, my body became weaker, my moral and physical powers were gradually declining; I observed with pleasure the gradual diminution of my strength, and I arrived at the point without pain, without regret, and by a very gentle declivity. Death is not to be feared, and when it comes without violence, it is a last function, which is neither painful nor disagreeable." Then he explained to them his ideas respecting life, the seat of which he considered as spread over the whole body, in every organ and all parts of the machine, which in his case became equally feebler in every part by the same degrees. "A little longer, and there would have been no functions, death would have overspread the whole body, for death is merely the absolute repose of the body; I wished to die," added he with greater force, "I found a pleasure in it; but my wife did not wish it. I should have preferred at that time a wife less kind, less eager to restore my strength, and who would have allowed me gently to have finished my career. I have performed my task. I have acquired some celebrity in the mathematics, I have hated nobody, I have done no ill; it is now proper to finish."

As he was very animated, especially at these last words, his friends, notwithstanding the interest with which they listened to him, proposed to retire. He retained them, began to relate to them the history of his life, of his labours, of his success, of his residence at Berlin, where he had often told us what he had seen near a king; of his arrival at Paris, the tranquillity he had enjoyed at first, the anxiety occasioned to him by the Revolution, and how he had been finally rewarded by a powerful monarch, capable of appreciating his worth.

He had neither been ambitious of riches nor honour; but he had received both with respectful gratitude, and rejoiced at the acquisition for the advantage of the sciences.

La Grange had not lost all hope of cure; he believed only that his convalescence would be tedious. He offered, when he recovered his strength, to go and dine at M. Lacepede's country house with MM. Monge and Chaptal, and proposed to give them details respecting his life which could be found nowhere else. These details are irretrievably lost. We do not even know to what he alluded, nor what he could have added to the second volume of the *Mecanique Analytique*, which was then in the press. We have just learned that the Countess la Grange has put into the hands of M. Prony the complete manuscript of the second volume, in which will be found important additions, and sections entirely written anew. By the care of an editor so skilful, and so devoted to the memory of the author, the philosophical world is sure of obtaining with the greatest accuracy and dispatch what is wanting to complete the work, and perhaps even memoirs entirely new.

"During this conversation, which lasted more than two hours, his memory often failed him; he made vain efforts to recover names and dates, but his discourse was always connected, full of strong thoughts and bold expressions." This exercise of his faculties wasted the whole remains of his strength. Scarcely had his friends left him, when he fell into a fainting fit, and he died two days after, on the 10th of April, 1813, at three quarters past nine o'clock in the morning.*

M. la Grange was of a delicate but good complexion. His tranquillity, his moderation, and austere and frugal regimen, from which he rarely deviated, prolonged his life to the age of 77 years, two months, and ten days. He was twice married: first at Berlin, in order to be on a footing with the rest of the academicians, none of whom were bachelors. He brought from Turin one of his relations. He married her, and lost her after a long illness, during which he had bestowed on her the most tender and unremitted care. When he afterwards married, in France, Mademoiselle Lemonnier, daughter of the celebrated astronomer of that name, he said to us, "I had no children by my first marriage; I do not know if I shall have them by my second; but I scarcely desire them." What he principally wished was an amiable companion, whose society might afford him some amusement during the intervals of his studies, and in this respect he was very successful. Madame la Grange, daughter, grand-daughter, and neice, of members of the Academy of Sciences, was deserving of the name which he gave her. This advantage in her eyes making up for the difference of their ages, she soon felt for him the tenderest regard. He was so grateful that he could scarcely bear to be separated from her, and it was on her account alone that he felt any regret at relinquishing this life; and he was often heard to say, that of all his good fortune, that which he prized the most was, having obtained a companion so tender and attached to him. During the ten days which his illness lasted, she never quitted him for a moment, and was constantly employed in recruiting his strength and prolonging his existence.

He loved retirement; but did not insist upon his young wife following his example. On her account he went out more frequently, and indeed his high situations obliged him to shew himself in the world. It was often apparent that he continued the meditations in public which he had begun in his cabinet. It has been said that he was not insensible to the charms of music. In fact, in a numerous company he was not displeased at a concert. On one of those occasions I asked him what he thought of the music: "I love it," says he, "because it leaves me to myself. I listen to it during the first three measures, but I hear no more of it; I give myself up to reflection, nothing interrupts me, and in this way I have solved many a difficult problem." Hence the finest music must have been that during which he was inspired with the finest of his thoughts.

Though he had a venerable figure, he would never allow his portrait to be drawn. More than once, by a very excusable piece of address, persons have been introduced during the meeting of the Institute, to take a sketch of him without his knowledge. An artist sent by the Academy of Turin drew in this manner the outline, from which was constructed the bust that was exhibited for some months in the hall of the Institute, and is at present in the library. A cast was taken of him after his death; and some time before, while he slept, a picture of him was taken, which is said to resemble him very much.

Gentle and even timid in conversation, he took a pleasure in asking questions, either to draw out others, or to add their reflections to his own vast knowledge. When he spoke, it was always in a tone of doubt, and his first words usually were, *I do not know*. He respected the opinions of others, and was very far from laying down his own as a rule. Yet it was not easy to make him change them. Sometimes he even defended them with a degree of heat, which continued to increase till he was sensible of some alteration in himself; then he immediately resumed his usual tranquillity. One day, after a discussion of this kind, M. la Grange having left the room, Borda remaining alone with me, allowed these words to escape him: "I am sorry to say it of a man like M. la Grange, but I do not know a more obstinate person." If Borda had gone away first, La Grange might have said to me as much of our associate, who was a man of excellent sense and considerable wit; but who, like La Grange, did not easily abandon those opinions which he had adopted after a mature examination.

A gentle and good-natured irony was often remarkable in the tone of his voice; but I never saw any person hurt at it; because it was necessary to have well understood every thing that went before, to perceive the true intention of it.

Among all the master-pieces which we owe to his ge-

* The body of La Grange was deposited in the Pantheon, beside those of a number of unknown senators. We copied the following inscription from his stone tomb.

Joseph Louis La Grange<br>
Senateur, Comté de L'Empire,<br>

nius, his *Mecanique* is certainly the most remarkable and the most important. The *Fonctions Analytiques* hold only the second place, notwithstanding the fruitfulness of the principal idea, and the beauty of the developments. A notation less commodious, and calculations more embarrassing, though more luminous, will prevent mathematicians from employing, except in certain difficult and doubtful cases, his symbols and names. It is sufficient that he has proved the legitimacy of the more expeditious processes of the differential and integral calculus. He has himself followed the ordinary notation in the second edition of his *Mecanique*.

This great work is entirely founded on the calculus of variations, of which he was the inventor. The whole flows from a single formula, and from a principle known before his time; but the whole utility of which was far from suspected. This sublime composition includes all his other preceding labours which could be connected with it. It is distinguished likewise by the philosophical spirit which reigns from one end of it to the other. It is likewise the best history of that part of the science,—a history which could only have been written by a man perfectly master of his subject, and superior to all his predecessors, whose works he analyses. It forms a most interesting piece of reading, even to him who is not capable of appreciating all the details. Such a reader will at least find the intimate connection of all the principles on which the greatest mathematicians have founded their researches into mechanics. He will there see the geometrical law of the celestial motions deduced from simple mechanical and analytical considerations. From these problems, which serve to calculate the true system of the world, the author passes to questions more difficult, more complicated, and which belong to another order of things. These researches are only objects of pure curiosity, as the author announces, but they show the extent of his resources. Finally, we see there his new theory of the variations of arbitrary constant quantities of the motion of the planets, which had appeared with so much eclat in the *Memoirs of the Institute*, where it had shown that the author, at the age of 75, had not sunk from the rank which he had filled for so long a time in the opinion of all mathematicians."

GRANGEMOUTH. See Borrowstoness and Stirlingshire.

GRANITE. See Mineralogy.

GRANSON, or Grandson, is the name of a small town in the canton of the Pays de Vaud. It is situated on the western bank of the lake of Neufchatel, about a mile from the foot of Mount Jura, which here bears the name of Thevenon. In approaching this town from Yverdun, it appears finely situated above the lake, and is particularly distinguished by its lofty chateau crowned with five or six towers. At the entrance to the town there is an old church, which does not appear to be used. The road passes through an arch surmounted with a tower and spire. The number of houses in 1814, when we passed through it, was 100. The opposite bank of the lake of Neufchatel is a lofty ridge, finely wooded, with the grand range of the eastern Alps towering above it.

Granson is celebrated in the history of Switzerland, for the great battle which the Swiss gained over Charles the Bold, Duke of Burgundy, on the 3d of March 1476. The Duke's army, which was 6000 strong, occupied Granson, and the villages of Possine, Corsalette, Giez, Vallieres, and Tuileries, and was defended on the right by the lake, and on the left by Mount Arnou, and on the east by the Thevenon, and by entrenchments on every other point. The battle began near Concise and the Chartreuse of Lalance, and terminated in the complete defeat of the Duke of Burgundy, who lost all his baggage and jewels.

One of his diamonds, which was the largest then known, was found by a Swiss soldier, and sold for a florin to the curate of Montagny. This diamond was afterwards sold to Pope Julius II. for 20,000 ducats. Other two diamonds were found by the Swiss, one of which now forms part of the imperial treasury of Vienna, and the other belongs to the crown of France.

GRANTHAM, a town of England in Lincolnshire, is situated on the river Witham, near the ancient Roman road, called Ermine Street. The town, which is neat and clean, and contains many excellent houses, consists of four principal streets, called Westgate, Watergate, Castlegate, and Swinegate. The church, which is elegantly built of stone, consists of a nave, with spacious north and south aisles. It is lighted with handsome painted windows, and has been celebrated for the elegance of its spire, which consists of a quadrangular tower, containing three stories. At each angle of the parapet is an hexangular crocketted pinnacle, over which rises an octagonal spire, ornamented with crockets in the angles, and at these several distances encircled with windows having triangular heads. The height of the tower to the battlements is 135 feet, and from that to the top of the vane 138, making a total height of 273 feet. The nave, including the chancel and side aisles, is 116 feet long inside, and 80 feet broad. The church contains several handsome marble monuments. The front, which is octangular, is deemed a handsome specimen of ancient sculpture. The crypt under the aisle is used as a charnel-house, which contains great numbers of bleached sculls and bones The vestry has been fitted up to receive the library of the Rev. Dr Newcome, a native of Grantham, who bequeathed it for the use of the town and neighbourhood.

The guildhall was rebuilt in 1787, and contains a large apartment for an assembly-room. The free-school was founded by Richard Fox, Bishop of Winchester, and in the present school-house Sir Isaac Newton studied the classics for several years. Without the Spittlegate is the Grantham Spa, a mild chalybeate, containing a small portion of aërated iron.

A canal has some time ago been cut from Grantham to the river Trent, a distance of 30 miles, with a fall of 148 feet to the river Trent. In 1798, 114,734*l.* had been expended on the undertaking, and the tonange then amounted to 4381*l.* Corn and coals are the principal articles which it conveys. There is a race-course in the neighbourhood of Grantham, where races are held annually.

The following is the population of the borough and parish, according to the census of 1811.

| | |
|---|---|
| Number of inhabited houses | 673 |
| Do. of families | 776 |
| Do. employed in agriculture | 61 |
| Do. in trade and manufactures | 430 |
| Males | 1677 |
| Females | 1969 |
| Total population | 3646 |

GRANTOWN. See Moravshire.

GRAPHOMETER, is a name sometimes given to instruments similar to goniometers, or to particular modifications of the theodolite. See Goniometer.

GRATZ, or Graz, is the name of an ancient town in the duchy of Styria, situated on the river Muehre. The town of Gratz is well built, the streets spacious and well laid out, and the houses, which are almost all of stone, are neat and commodious. The town, properly so called, is very small, and is surrounded with walls, ditches, and fortifications; but the suburbs are very large, and have lately increased with rapidity. The suburbs lie round the town like distinct villages, and are intermingled with gardens and vineyards. The citadel is situated within the town, on a very steep hill, about 600 or 700 feet above the level of the river, and has a well communicating with the Muehre. It was once a place of considerable strength; but it has been so much neglected, that in the year 1797, it offered no resistance upon the approach of the French. One of the principal objects of interest at Gratz is the imperial mausoleum of Ferdinand II. who was born in this town in 1578. The architecture is not in the best style; but its interior is richly ornamented with sculpture. The life of the Emperor Leopold is represented on the roof, in several emblematic paintings. On the top of the mausoleum is an observatory, which was once well furnished with astronomical instruments. The emperor's second son John Charles, and Mary Anne, Duchess of Bavaria, his consort, are buried along with Ferdinand in the circular chapel in the lower part of the mausoleum.

The assembly-room and the theatre, which are both under one roof, form a very extensive building. The arsenal, the house of the states, and the private residences of the Count Sauran, Loibel, and Wermbrand, are the other buildings deserving of notice. The castle, which was formerly the residence of the Dukes of Styria, is now the dwelling of the governors, and the seat of the regency. The house in which Bonaparte resided is very spacious, and is now shown as one of the curiosities of the town. Gratz is the see of a bishop, who generally resides at it about eight months in the year.

At no great distance from the town are several handsome villages, and the intermediate space between them and the suburbs is covered by country houses, large and small, farm houses, and detached cottages, so that the whole of this tract, when seen from the citadel, forms a rich and pleasing picture, and not only occupies a plain of above 18 square miles, but encroaches even upon the neighbouring hills. These hills are of a moderate height, and are partly covered with wood, and partly occupied with fields, vineyards, and meadows, up to their very summits. The population of Gratz has been stated in some statistical tables at 40,000; but it probably does not exceed 33,000. The population of the circle of Gratz, one of the five circles of Styria, is 296,424. East Longitude, according to accurate observations, 15° 27′ 15″, North Latitude 47° 4′ 9″. See Styria.

GRASSES. See Agriculture *Index*.

GRAVE-Harmonics, in Music. See Harmonics, *Grave* and *Acute*.

Grave *Intervals*, according to Maxwell and Liston, are such as are lessened by the major comma; they are marked with the grave accent (\`), and are usually called by us, *Comma-deficient* intervals.

The Grave *Diesis* of Liston, $\mathcal{E}' = \mathcal{E} - c = 10\Sigma + m$, is the *Minor* Comma, which see.

The Grave *Limma* of Liston, $S' = S - c, = 36\Sigma + f + 3m$, is the Semitone *Minor*, which see.

The Grave *Tone* of Liston, (p. 14.) $T' = T - c, = 93\Sigma + 2f + 8m$, is the Tone *Minor*, which see.

Grave *Fourth* of Holden, or bearing fourth, has the ratio $\frac{16}{21}$, $= 240.06077\Sigma + 5f + 20m$; and is the *Lesser false* Fourth of the trumpet, which see.

Grave *Semitone* of Holden, or deficient semitone of the same author, (p. 341.) has the ratio $\frac{20}{21}$, $= 43.052904\Sigma + f + 4m$; its common log. $= .9788107,0093$; it is $+ 43.234017 \times \Sigma, = 3.92754 \times c, = .070389 \times$ VIII. M. Feyton mentions it as his *Semitone* E E♯, and it is the *Semitone* of Ptolemy's Diatonicum molle.

GRAVEL. See Medicine.

GRAVER. See Engraving.

GRAVESEND, is a town of England, in the county of Kent, built on a gentle declivity, on the banks of the Thames. It consists of several narrow streets, the best of which are the one on the great London road, and another at right angles to it, leading to the river. The church, which is dedicated to St George, was erected near the river between 1731 and 1733. It is built of brick, with stone quoins and cornices, and consists of a spacious nave and chancel, &c. The town-hall was erected in 1764, and has a poultry market below it. It is supported by six columns in front, and three arches behind. A neat little theatre, with a brick front and wooden sides, and a small projecting wooden portico, surmounted by a bust of Shakespeare, was built in 1808; and a handsome chapel in 1812, on the north side of the London road. A new wharf and crane were erected in 1767, and two batteries of 16 guns each have more recently been built, for the defence of the town. There is here a small manufactory for cables and ropes, and a yard for ship-building. Most of the outward bound ships are supplied with live and dead stock at Gravesend, and also with vegetables, for the cultivation of which about 80 acres of ground are appropriated. The town is often crowded with seamen and strangers, from the great quantity of shipping that usually lie at anchor in the channel near the town; and in summer many visitors are attracted by the accommodations of a new bathing-house, which was built by subscription in 1796. About 18 or 20 Gravesend smacks are employed in the cod and haddock fishing.

According to the population return for 1811, Gravesend parish contains

GRAY, Thomas, an eminent English poet, was born at Cornhill in London, on the 20th of December 1716. His father, Philip Gray, was a money scrivener of the city. His mother, whose maiden name was Dorothy Antrobus, was, owing to the bad usage of her husband, obliged to apply to an eminent civilian for his advice as to a separation from him. Our poet, their fifth child, owed his life to the affectionate courage of his mother, who, by opening a vein with her own hand, removed a paroxysm which attacked him in his childhood. To this parent's exertions he was also indebted for his education; so that, considering the unhappiness of her life, and the gratitude which her son owed her, we can easily conceive the truth of what Mason tells us, that Gray always mentioned his mother's name with a sigh. Gray was educated at Eton, under the protection of Mr Antrobus, his maternal uncle, who was a fellow of Peterhouse, Cambridge. At that university, Gray was admitted a pensioner in his 19th year. During his first four years residence there, he seems to have withdrawn himself from the severity of mathematical studies, while his enquiries centered in classical and modern literature.*

In 1738, he removed to the Inner Temple; but laid aside his legal studies to accompany Horace Walpole on a tour through France and Italy. An unhappy difference, however, with the blame of which Walpole has candidly charged himself, parted the travellers at Reggio, and their broken friendship, in spite of a formal reconciliation, seems never to have been entirely cemented. Gray returned to London in 1741, in the same year in which his father died. His mother, with a very small fortune, had retired to live with her sister at Stoke, near Windsor. Mr Gray, therefore, found his patrimony too small to enable him to prosecute the study of the law; and though his mother and aunt would undoubtedly have contributed all in their power to assist him, he could not brook the idea of becoming a burthen to them. Yet such was his delicacy, that he could not peremptorily declare to his relations his resolution of abandoning his profession: he therefore pretended only to change the line of it, and accordingly he went to Cambridge, where he took a bachelor's degree in civil law. In the same year in which he graduated, (1742) he lost his friend West, with whom his friendship had commenced at Eton, and had continued with unabated warmth after they had gone to different universities. The sorrow which the death of this amiable young man left upon our poet's mind, and the tenderness with which he honoured his memory, form one of the most interesting traits of his character.†

On his second return to Cambridge, he applied himself for about six years with the most intense assiduity to the perusal of Greek authors, and made himself a consummate scholar and critic in that language. In 1747, he appeared for the first time as an author, by the publication of his Ode on the prospect of Eton College, of which it would seem that at first little notice was taken. His Ode to Spring had been already written at Cambridge; and soon after the publication just mentioned, he sent to Dr Wharton of Durham, his poem on the Alliance of Education and Government, which he never pursued much farther. In 1749, he finished his Elegy, which he had begun seven years before, and which when published obtained immediate popularity.

In 1754 and 1755, he appears to have written his beautiful lines on the Pleasures arising from Vicissitude, his Ode on the Progress of Poetry, the Bard, and probably some of those fragments with which he seems to have amused himself, without much design of completion. About this period, he complains of listlessness and depression of spirits, which prevented his application to poetry; and from this time we may trace the course of that hereditary disease in his constitution, which the temperance and regularity of a whole life could not subdue. Next year, he left Peterhouse at Cambridge, where he had resided above twenty years, on account of some incivilities which he met with, and which Mason thus mentions. Two or three young men of fortune, who lived on the same staircase, had for some time intentionally disturbed him with their riots, and carried their ill behaviour so far as to awaken him at midnight. After having borne a considerable time with their insults, Gray complained to the governing part of the Society, and not thinking that his remonstrance was sufficiently attended to, quitted the College. He now removed to Pembroke Hall, which he describes "as an era in a life so barren in events as his"

In the July of 1757, he took his Odes to London to be published. "I found Gray (says H. Walpole) in town last week. He brought his two Odes to be printed. I snatched them out of Dodsley's hands, and they are to be the first fruits of my press." Although the genius of Gray was now in its firm and mature age, and though his poetical reputation was deservedly high, it is plain that these Odes were not favourably received. "His friends (he says) write to him that they do not succeed." Yet there were some better judges who admired them. Garrick wrote lines in their praise; and Warburton, while he bestowed his honest applause on them, shewed his indignation at those who condemned without being able to understand them. In this year Cibber died, and the laureateship was offered by the Duke of Devonshire, then Lord Chamberlain, to Gray, with a remarkable and honourable privilege to hold it as a mere sinecure. This offer he respectfully declined; and in a letter to Mr Mason, he gives some of his reasons for declining it. "The office itself (he says) has always humbled the possessor hitherto:—if he were a poor writer, by making him more conspicuous; and if he were a good one, by setting him at war with the little fry of his own profession: for there are poets little enough even to envy a poet laureat." In 1758, Gray describes himself "as composing for his own amusement the little book, which he calls a Catalogue of the Antiquities, Houses, &c. in England and Wales."‡ About this time, the study of architecture seems to have employed much of his time, in which his proficiency (as in every branch of study which he pursued) was accurate and deep. Early in the next year the British Museum was opened to the public, and he went to London to read and transcribe the MSS. which were there collected from the Cottonian and Harleian libraries. A folio volume of his transcripts was left among his papers. No other remarkable date occurs in the peaceful tenor of our poet's days, till in 1762, the professorship of modern history being vacant, by the advice of his friends, he applied to Lord Bute for the place, through the medium of Sir Henry Erskine. He was refused, and the professorship was given to another; and "so (says Gray) I have made my fortune like Sir Francis Wronghead."

In the summer of 1765, he took a journey into Scotland to improve his health, which was then weak, and to gratify his curiosity with the romantic scenery of the north. He went through Edinburgh and Perth to Glammis castle, the residence of Lord Strathmore, where he stayed some time. Thence he took a short excursion into the Highlands, crossing Perthshire by Loch Tay, and pursuing the road from Dunkeld to Inverness, as far as the pass of Killikrankie. Then returning to Dunkeld, he travelled on the Stirling road to Edinburgh. In Scotland, his general shyness to men of letters was felt and complained of; but he formed an acquaintance with Dr Beattie, which was kept up by subsequent correspondence. The university of Aberdeen was disposed to confer on him the degree of Doctor of Laws; but he refused it, lest it should seem a slight to his own university. At Dr Beattie's desire, a new edition of his poems was published by Foulis at Glasgow, whilst Dodsley at the same time was printing them in London. In both these editions the long story was omitted, and some Welch and Norwegian fragments inserted in their place.

* His productions during that period, were some Latin verses, entitled *Luna Habitabilis*, inserted in the *Musæ Etonenses*; a poem on the marriage of the Prince of Wales; and a Sapphic Ode to his friend West, both in Latin. A latin version of a passage of the *Pastor Fido*, and Fragments of Translations from Italius and Tasso.

† Richard West was the son of the Lord Chancellor of Ireland, and grandson by the mother's side of the famous Bishop Burnet.

‡ It was printed and distributed among his friends by Mr Mason after his death.

To his Odes, Gray now found it necessary to add some notes; "partly," he says, "from justice, to acknowledge a debt when I had borrowed any thing; partly from ill temper, just to tell the gentle reader, that Edward I. was not Oliver Cromwell, nor Queen Elizabeth the witch of Endor."

In 1768, the professorship of modern history became again vacant, and the Duke of Grafton, then in power, at the request of Mr Stonehewer, bestowed it on Gray. Soon after the Duke of Grafton was elected to the chancellorship of the university, and Gray wrote the Ode, that was set to music, on the occasion of his installation. "He thought it better that gratitude should sing than expectation." When this ceremony was past, he went on a tour to the lakes of Westmoreland and Cumberland, from which his letters are written in a style of the most picturesque description. "He that reads his epistolary narrative," says Dr Johnson, "wishes that to travel, and to tell his travels, had been more of his employment."

In the April of 1770, he complains much of a depression of spirits, and talks of an intended tour into Wales, which took place in autumn; but not a single letter is preserved in Mr Mason's book on this journey.

In May 1771, he wrote to his friend Dr Wharton, just sketching the outline of his tour in Wales, and some of the adjacent country. This is the last letter that remains in Mr. Mason's collection. He there complains of an incurable cough, of spirits habitually low, and of the uneasiness which the thought of the duties of his profession gave him, which, Mr. Mason says, he had now a determined resolution to resign.* He mentions also different plans of amusement and travel which he had projected, but which unfortunately were not to be accomplished. Within a few days after the date of this letter he removed to London, where his health more and more declined. His physician, Dr Gisborne, advised free air, and he went to Kensington. There he in some degree revived, and returned to Cambridge, intending to go from that place to Old Park, near Durham, the residence of his friend Dr Wharton. On the 24th of July, however, while at dinner in the college hall, he was seized with an attack of the gout in his stomach. The violence of the disease resisted all the powers of medicine. On the 29th he was seized with convulsions, which returned more violently on the 30th, and he expired on the evening of that day, in the 55th year of his age, sensible almost to the last, aware of his danger, and expressing no visible concern at the thought of his approaching death. His friend, Mr Mason, was at that time absent; and the care of his funeral devolved on the other executor, Dr Brown, the president of Pembroke hall, who saw him buried, as he desired, by the side of his mother, in the churchyard of Stoke.

Gray, independently of his poetical character, sustained that of a first-rate scholar. He was perhaps (says the Rev. Mr Temple, in the summary of his character) the most learned man in Europe. He knew every branch of history, natural and civil; had read all the original historians of England, France, and Italy; and was a great antiquarian. His skill in zoology was accurate; and in an interleaved copy of Linnæus which he had left behind, he had not only concentrated what other writers had written, but had altered the style of the Swedish naturalist into classical Latin.† Botany, which he had studied in early life, was also an amusement of his later years. In architecture he was eminently skilled; and in heraldry a complete master. To these accomplishments must be added his exquisite and scientific taste in painting and music. Walpole, in his History of Painters; Bentham, in his History of Ely; Pennant, in his Antiquities of London; and Ross, in his edition of Cicero's Familiar Epistles, were all respectively indebted to the learning of Gray.

As a man, the only blemish in his fine character seems to have been an excessive and half-affected delicacy. His genius as a poet is not of the most extensive, but of the highest cast. He is the only English poet who has divested elegiac poetry of its tædium; placed its sombrous images in a light of picturesque fancy; and given a tone of stedfast though subdued romantic feeling to the plain reflections of truth. Respecting his lyric poetry, the suffrages of criticism are certainly more divided. While by some his Odes have been extolled as the model of lyric poetry, they are esteemed by another school of taste to abound in over-wrought refinements, and obscurity of language. Our limits preclude dissertation; yet whatever justice there may be in the charge of obscurity which attaches to his Odes, the grandeur of thought, and the harmony of versification, which pervade them, will for ever support their general merit, and their rank in the first rate productions of our language, and the muse of England will be for ever acknowledged to have expressed

A Pindar's raptures in the lyre of Gray.

GRAZING. See AGRICULTURE.

GREAT INTERVALS, in music, are the same with *major* or *greater* intervals, and are marked with the large Roman numerals; as I. II. III. IV. &c. See MAJOR *Intervals*. But Mr Holden has used this term in a different way. See his *Great* SIXTH, and *Great* THIRD (*ϱ*)

GREAT OCTAVE of the German theoretical writers on music, is that octave (or septave rather) which begins with C on the second leger line below the bass stave, and ends with B on the second line of that stave, or the *mi* of Guido. To this septave they exclusively apply the capital letters C, D, E, F, G, A, B, in their tablature or literal notation; and in the next octave above, the letters c, d, e, f, g, a, b are used. See SMALL OCTAVE, ONCE-MARKED, TWICE-MARKED, &c. *Octaves*; and Dr Callcott's *Musical Grammar*, Art. 34. (*ϱ*)

GREAT SCALE of M. Overend, approved by Dr Boyce, is a musical curiosity preserved in the library of the Royal Institution in London, in the Overend Manuscripts, vol. ii. pp. 113—133, 143—149, &c. It contains 86 notes within the octave, and was thought by the indefatigable musicians above named, to be capable of unravelling all the mysteries of the various ancient Greek scales of music, as Dr Pepusch had explained them diatonically, or by the use of the prime integers, 1, 2, 3, and 5 only, in their ratios; but to the various systems of those, who, according to Dr Wallis, used the higher primes 7, 11, 13, 17, 19, &c. in the ratios, and in consequence have *decimals* of schismas, or Σ's in our notation; or of those, who divided the major *tone*, or the minor *fourth*, into *aliquot parts*, for obtaining their intervals or degrees, this great scale has no near relation. See CHROMATICUM, DIATONICUM, GENERA, and GREEK *Music*. (*ϱ*)

* He had held his professorship of history nearly three years, without having begun to execute the duties of it, which consist of two parts; one, the teaching of modern languages; the other, the reading of lectures on modern history. The former he was allowed to execute by deputies; but the latter he was to commence in person, by reading a public lecture in the schools once at least in every term. He was at liberty to chuse his language, and chose the Latin, which Mr Mason thought somewhat injudicious; and although we do not find that he proceeded farther than to draw up a part of his introductory lecture, he projected a plan of very great extent, which, from his indolence and ill health, he would not in all probability have been able to execute. His death, however, prevented the trial.

† It is a circumstance not generally known, that he translated the Linnæan genera, or characters of insects, into elegant Latin hexameters.

# GREECE,

THE most celebrated country of antiquity, was of very inconsiderable extent, and scarcely equalled in size the half of England. It is comprehended between 36° and 41° of North Latitude; and is bounded on all sides by the sea, except on the north, where it borders upon Epirus and Macedonia. Thessaly, its most northern province, is an extensive and fertile vale, completely surrounded by lofty mountains; by Olympus on the north; by Ossa on the east; by Pindus on the west; and on the south by Oeta, at the foot of which lies the famous pass of Thermopylæ. The tract extending from the borders of Thessaly and Epirus, to the Corinthian isthmus, contains the provinces of Acarnania, on the east frontier of which runs the river Achelous; Ætolia, bounded on the south by the sea, but defended on every other side by mountains almost impassable; Doris, wholly a mountainous country; Locris and Phocis, both of small extent, but full of fertile plains; Bœotia, a well watered vale, bounded, except on the north-east, by the mountains Parnassus, Helicon, Cithæron, and Parnes; and Attica, a rocky and barren country, producing little grain or pasture, but yielding a variety of fruits, particularly figs and olives. The isthmus of Corinth, a mountainous ridge, at one place only five miles in breadth, leads farther south to the peninsula of Peloponnesus, which contains Achaia, a narrow strip of country on the northern coast, bounded on its inland frontier by a ridge of mountains, running along its whole extent from Corinth to Dyme; Argolis, a remarkably fruitful valley, included between two mountainous branches, stretching from Cyllene, the most northern of the Arcadian summits, and terminating, the one in the gulf of Argos, and the other at the promontory of Scylla; Elis, or Eleia, watered by the rivers Peneus and Alphcus, and less mountainous than the other provinces in Peloponnesus; Arcadia, the central state, consisting of a cluster of lofty mountains, the principal of which are Taygetus and Zarex; Messenia, the most level district in the peninsula, the best adapted for tillage, and most fruitful in general produce; and Laconia, traversed by two branches of the Taygetus and Zarex, between which runs the river Eurotas, watering several very fertile but not extensive vales.

The general aspect of Greece is rugged, but its climate is highly propitious; and both the summer heat and winter cold are preserved by the surrounding seas in an equable state of temperature. Some of its mountains contain valuable metals; others are composed of the finest marble; and many are covered to a great extent with a variety of useful timber. Its central plains produce corn, oil, and wine; its valleys afford the richest pasturage; and its long winding coast abounds with excellent harbours. The great variety in its surface gives occasion to considerable diversity both of produce and of climate in every season of the year. It has been remarked, as a peculiar feature in the topography of the most ancient cities of Greece, that every metropolis possessed its citadel and its plain; the former as a place of refuge in war, and the latter as a source of agriculture in peace. The most remarkable of its towns were,—in THESSALY, Gomphi, Metropolis, and Scotussa, north of the river Peneus; Atrax, Larissa, the city of Achilles; Magnesia, and Aphetæ the port of the Argonauts; Heraclea, named from Hercules, who is said to have thrown himself into the pile on the summit of Oeta, in its vicinity; Lamca and Hypata, on the banks of the Sperchens; Thaumaci, Halos, and Pthia, the country of the Myrmidones, Demetrias, Pheræ, Pharsalia, on the banks of the river Enipeus.—In ACARNANIA, Amphilochicum, Stratus, and Actium, at the bottom of the Ambraeian Gulf.—In ÆTOLIA, Chalydon, Chalcis, on the river Evenus; Thermæ, Lysmachia, Canope, Naupactus, Erythræ, and Antirrhium.—In DORIS, Cytinium, and three smaller towns of little note.—In LOCRIS, Amphissa, Opus, Cnemis, Narix, the native country of Ajax, Thronium, Nicæa.—In PHOCIS, Delphi, accounted the centre of Greece; Elatea, on the river Cephissus; Crissa, and Anticyra.—In BŒOTIA, Thebes, near the river Asopus; Platæa, Leuctra, Orchomenos, Haliartus, Coronea, Cheronea, Lebadia, Thespiæ; Ascra, the birth-place of Hesiod; Aulis, Delium, and Tanagra.—In ATTICA, Athens, with its harbour Piræus; Phalereus and Munichia, Marathon, Phylæ, and Decelia.—In MEGARIS, Megara, Eleusis, and Nycæa.—In ACHAIA, Corinth, Sicyon, Patræ, Ægium, Dyme, and Pallene.—In ARGOLIS, Argos, on the river Inachus; Mycenæ, the city of Agamemnon; Epidaurus, Nemea, and Tiryns.—In ELIS, Elis, on the river Peneus; Olympia, and Pisa.—In ARCADIA, Megolopolis, Tegea, Mantinea, and Pallantium.—In MESSENIA, Messene, Stenyclarus, and Pylos, the city of Nestor.—In LACONIA, Sparta, on the river Eurotas; Gythium, Selasia, Helos, Amyclæ.

It has been customary with most writers on the subject of Greece, to distribute its history into distinct periods or epochs; but few authors happen to agree in fixing upon the same points of division. If we proceed upon the principle of marking the degree of credibility in its records, there will then be only two portions to be contrasted; the one the period of uncertain, and the other that of authentic history.

The *first*, "the period of uncertain history," extends from the earliest accounts of the country, to the commencement of the first war with Persia, in the year B. C. 490; a period very variously computed, but, according to the lowest estimate,* comprising a space of nearly 700 years. Of this large portion of time, there are no documents really deserving the name of history; and the accounts which have been given of its events, were drawn up by writers who lived long posterior to the transactions of which they treat, and were compiled from scattered records and fragments, of which there are no sufficient data to ascertain the authenticity. Of this period, however, there may be specified four distinct subdivisions, which are marked by some peculiar historical features. The first, reaching from the earliest accounts of Greece to the commencement of the Trojan war, B. C. 900; a period of 200 or 300 years, and which, without scruple, may be termed "the fabulous age." The second, reaching from the expedition against Troy to the death of Homer, B. C. about 800; a period of at least 100 years, generally called "the heroic age," of which the only history is contained in the poems of the Iliad and Odyssey. The third, reaching from the death of Homer to the death of Lycurgus, B. C. about 700; a period of another 100 years, which may be denominated "the era of revolutions," and

* The Chronology of Sir Isaac Newton.

of which scarcely any species of history exists. The fourth, reaching from the time of Lycurgus to the first invasion of Greece by Persia, B. C. 490; a period of 210 years, which may be termed "the era of traditionary history," possessing a considerable degree of credibility.

The *second*, "the period of authentic history," extends from the first invasion of Greece by the Persians, B. C. 490, to its final subjugation by the Romans, B. C. 146; a period of 341 years, the history of which, luminous and connected beyond that of any other portion of Pagan antiquity, has been recorded by writers of the greatest ability, who were contemporary with the events which they relate, and in which many of them bore a distinguished part. These writers were all Greeks, and some degree of national partiality may be suspected to have guided their narrations; but their number, and their connection with different states, renders them in some measure checks upon one another. This period, also, may be subdivided into four portions, distinguished rather by political than historical characteristics. The first, reaching from the Persian invasion, B. C. 490, to the commencement of the Peloponnesian war, B. C. 430; a period of 60 years, the era of Grecian unanimity and triumphs. The second, reaching from the beginning of the Peloponnesian war, to the accession of Philip of Macedon, B. C. 360; a period of 70 years, the era of civil wars and intestine commotions among the states of Greece. The third, reaching from the accession of Philip to the death of Alexander the Great, B. C. 323; a period of 37 years, distinguished by the entire ascendency of Greece over Persia, and its own partial subjection to the foreign dominion of Macedonia. The fourth reaching from the death of Alexander, to the final subjugation of the Grecian states by the Romans, B. C. 146; a period of 177 years, during the greater part of which the destinies of Greece were directed by foreign influence, and were placed successively under the protection of Macedonia, Egypt, and Rome.

The early history of Greece, like that of most other countries, is involved in obscurity and fable. Its original inhabitants, generally considered as the descendants of Javan, son of Japhet, appear to have led a migratory and savage life, sheltering themselves in caves and huts, feeding upon acorns, clothing themselves with skins, and gradually associating in small bodies for their mutual support against the wild beasts of the woods and mountains, by which they were every where surrounded. Many different wandering hordes, of whom the Greek writers give no satisfactory account, seem to have successively overrun the country; sometimes mixing with the ancient inhabitants, and sometimes driving them from their possessions. These, in their turn, expelled and plundered others; and a state of petty piratical warfare characterised the first ages of every Grecian settlement. These plundering excursions became so general, that all the shores, both of the continent and the islands, are said to have been deserted, and the lands cultivated only at a considerable distance from the sea. From this state of barbarism, the inhabitants of Greece began to emerge at an earlier period than those of any other country in Europe; and this advantage they seemed to have owed entirely to their communication with the civilized nations of the East. Its islands were visited by the Phenician navigators, who introduced the knowledge of the precious metals. A people, named Pelasgi, apparently from Asia, extended their dominion over all the northern parts of the country; and various contemporary colonies from Egypt, (of whose migration the cause is not known, but for which the supposition of some political revolution may easily account,) appear to have founded the principal Grecian states. The island of Crete, which seems to have been occupied, and its inhabitants enslaved by some of these adventurers, first attained a considerable degree of civilization under Minos, above 1000 years before the Christian era;* and became the general foundation of legislation and jurisprudence to the other settlements. Of these, Sicyon and Argos are considered as the most ancient, and as having been founded nearly at the same time, about 80 years before the reign of Minos, and 1080 before the Christian era.

Sicyon, till a very late period, had little influence in the affairs of Greece; and its early history is as uninteresting as it is uncertain. Ægialeus is mentioned as its first king; but the list of his successors rests on no authority, and is not worthy of being transcribed. It seems to have been soon eclipsed by the neighbouring state of Corinth, which was noted, even in the days of Homer, for its commercial wealth. Among its early princes are numbered Sisyphus, Glaucus, and Bellerophon, whose exploits present a subject for poetry rather than materials for history. But the city of Argos, if not actually the oldest in Greece, was the first that acquired political eminence; and was founded by Inachus, or by his son Phoroneus, who is considered as having been the contemporary and brother of Ægialeus, the first king of Sicyon. Io, the daughter of one of the Argive princes, having been carried away to Egypt, her descendant Danaus, afterwards arriving at Argos, claimed the sovereignty, and extending his power over the whole of Peloponnesus, the inhabitants (called Pelasgi before his arrival) received from him the name of Danai. Perseus, one of his descendants, and the first Grecian who is celebrated as a warrior, founded the city of Mycenæ, which became for some time the capital of Argolis; but soon afterwards lost its pre-eminence. Contemporary with Perseus was Pelops, son of Tantalus, king of Phrygia, who, being driven from his native land by unsuccessful war, came with immense treasures into Greece; and, being accompanied by a band of Achaians from Thessaly, established himself in Laconia. Marrying Hippodameia, daughter of the chief of Pisa, he succeeded to the sovereignty of that territory; and, by his numerous family connections, as well as able conduct, acquired so much influence throughout the peninsula, that it derived from him the name of Peloponnesus. His daughter Astydameia was united in marriage with Sthenelus, the son of Perseus; and their son Eurystheus was the prince so often mentioned in Grecian fable as the rival and persecutor of his kinsman Hercules. Pursuing the children and adherents of that deceased hero into Attica, he was slain in battle, and succeeded in the sovereignty of Argos by his uncle Atreus, who uniting in his person the claims of both the houses of Perseus and Pelops, extended his authority over all Peloponnesus, and transmitted the Argian sceptre in its greatest glory to his son or grandson Agamemnon. Lacedemon, or Sparta, concerning the origin of which there is no certain memorial, had now become distinguished under its sovereign Tyndareus, whose sons Castor and Pollux died in the prime of life, and whose daughters, Clytemnestra and Helen, were given in marriage to Agamemnon and his brother Menelaus. Through these princesses, the domains of Tyndareus fell to the two sons of Atreus; and Menelaus was invested with the immediate command of the Lacedemonian territory.

Of the provinces without the peninsula, Thessaly (next to Crete, the most ancient scene of Grecian story,) first became celebrated for the wisdom of its princes, who extended their sway at an early period as far as the Corinthian

* The chronology of Sir Isaac Newton is here followed.

Isthmus. In that country, always famous for its horses, the Centaurs were first known, who are supposed to have been a band of foreign adventurers of superior attainments to the more southern Greeks of their time. From a port in Thessaly, sailed the expedition of the Argonauts under Jason, who may be considered as merely the leader of one of the most considerable piratical expeditions which had hitherto been undertaken. Bœotia, though a country originally subject to earthquakes and inundations, yet, from its great fertility, attracted at an early period the attention of adventurers; and a Phenician colony under Cadmus is understood to have founded its principal city of Thebes. The numerous fabulous stories relating to its history, comprehending the adventures of Bacchus, Amphion, Amphitryon, Hercules, Laius, Œdipus, Eteocles, and Polynices, serve at least to prove that it must soon have become a flourishing and powerful state; and the war, which it sustained against seven united potentates, the subject of the *Thebaid* by Statius, presents the first instance of a political league, and a regular warfare, recorded in the annals of Greece. Ætolia, though not inferior to the adjoining countries in early civilization, and though sufficiently celebrated in the histories of its heroes Tydeus, Meleager, and others, yet, from the dangers of its seas, being much excluded from the intercourse of more civilized nations, made little comparative progress in political improvement, and for several centuries, even after the Trojan war, had little communication with the rest of Greece. Phocis, Doris, and Locris, also afford no materials for history at this early period; and the only remaining state, whose origin is worthy of being narrated from tradition, is that of Attica. The first king of this country is said by some to have been Ogyges, whose name, however, is not mentioned by the older Greek historians, and who is conjectured at the utmost to have been only the leader of a band of Bœotians, who, having been driven from their own country by an inundation, had taken refuge in the adjoining districts of Attica. The first, at least, who introduced regular government and the arts of civilization among the Athenians, was Cecrops, the leader of a colony from Egypt, who introduced the worship of the goddess Athena, or Minerva; and thus gave a name, if not also a beginning, to the city of Athens. He is considered as the founder of the celebrated court of Areopagus; and, in consequence of his wise institutions, aided by the natural security of the country from invasion, strangers were attracted, population increased, and civilization made more rapid progress than in any other province of Greece. Of his successors, little is recorded even by tradition, till the time of Ægeus, contemporary with Minos, King of Crete, and the father of the renowned Theseus, whose romantic history bears no inconsiderable resemblance to that of the Gothic knight-errants, and whose wise measures as king of Athens laid the foundation of its future greatness. By the united influence of persuasion and authority, he consolidated, in one well-regulated government, the independent districts in Attica, and endeavoured to secure the stability of his improvements, by procuring the approbation of the Delphic oracle. Though well entitled, by his political regulations, to be ranked among the most illustrious patriots of ancient times, he is nevertheless represented, in his future history, as having forfeited the esteem of his subjects, and having at last died in exile. After him the sovereignty of Attica was held by Menestheus, a descendant of the royal family, and the leader of the Athenian troops in the Trojan war.

These petty states, each of which was governed by its respective sovereign, and all of them independent of one another, were continually at war among themselves, and exposed to the incursions of foreign barbarians. To obviate these evils, and to secure, as far as possible, the general tranquillity, an assembly was formed of deputies from the different countries of Greece. whose business it was to decide all disputes between the states of which the association was composed, and to concert measures of defence against their common enemies. This was called the council of the Amphictyons, from its supposed founder Amphictyon, one of the sons of Deucalion, and king of Attica; but its original constitution, and the period of its commencement, cannot be satisfactorily ascertained. It is supposed by Sir Isaac Newton to have commenced about a century before the Trojan war. Besides its primary object of establishing a kind of national law among the Greeks, its attention was principally occupied in managing the concerns of the Delphian oracle. But, though its decrees were respected, its power was not very efficacious. It contributed to restrain the violence of wars, but was not able to prevent their frequent occurrence. It derived its greatest consequence from the increasing fame of the oracle at Delphi; and the superintendence of the religious institutions of Greece became ultimately its principal office. It is not mentioned by Homer; but its existence seems to be implied in the ready union of the Grecian states against Troy. See Amphictyons, Cadmus, &c.

Frequent piratical excursions appear to have been carried on between the inhabitants of the eastern and western coasts of the Ægean Sea; and the rape of Helen by Paris, the son of Priam, may be considered, according to Herodotus, as an act of retaliation for some similar injury received from the Greeks by the Trojan people. An outrage, however, so nearly affecting one of the greatest princes of Greece, and aggravated by a breach of the rights of hospitality, was considered as demanding the united vengeance of the Grecian chiefs; and the hope of returning home enriched with the spoils of Asia, presented no small incentive to the expedition. The extensive influence also of Agamemnon king of Argos, and brother of the injured Menelaus, urged on the general confederacy; and, under his supreme command, the chosen warriors of every Grecian state, from the southern extremity of Peloponnesus to the northern regions of Thessaly, assembled at the port of Aulis in Bœotia. The fleet, consisting of 1200 open vessels, conveyed to the Trojan coast an army of 100,000 men, who speedily compelled the enemy to take refuge within the walls of their city; but, unable to surmount its strong and well defended fortifications, they attempted its reduction by excluding every kind of succour and supplies. Obliged, however, to detach large bodies from their army to procure subsistence for themselves, they were unable to prevent the Trojans from again taking the field, and receiving every requisite relief to their wants. In this way the siege was prolonged for the space of ten years: and even at the last, the house of Priam was not overthrown without the aid of stratagem and treachery. But, while the allied Greeks triumphed over Troy, it was to each of them a victory dearly purchased. Few of the princes, who witnessed the successful termination of their expedition, were permitted to enjoy, in their native country, the renown and repose which their exertions had earned; but, having made no provision for the administration of their affairs during their absence, were either murdered at their return by some usurper of their power, or compelled to reimbark with their adherents, in quest of distant settlements. The Athenian state, which seems to have made the nearest approach to a settled government, suffered least by the absence of the commander of their army; and regular magistrates supplied the place of their chief. In this city, Orestes, the son of Agamemnon, obtained an asylum; and, after remaining seven years in exile, found means to avenge his father's death, and to recover the throne of Argos, which he held with great power and reputation till his death. See ACHILLES, AGAMEMNON, AJAX, HOMER, TROY, &c.

Here terminates the history contained in the writings of Homer, who seems to indicate, that the concluding events which he records were within the reach of his own memory; and whose works, in fact, contain almost the only materials for an account of the heroic age. He affords at least the best and most authentic view of the political and domestic state of the Greek people, during the period which preceded his death; and to his poems we may refer for a description of the religion, government, arts, and manners of the early Greeks. The ancient Pelasgian inhabitants of Greece are said by Herodotus to have prayed and sacrificed to gods, to whom they gave no name or distinguishing appellation; and the works of Hesiod still more clearly prove that they drew their first notions on the subject of religion from Oriental traditions. Their future system of polytheism seems to have been imported by the Egyptian colonists; but to the principal divinities thus introduced, their own lively fancy soon added a multitude of other imaginary beings, presiding over every mountain and river, every season and production; and these were arranged by Hesiod and Homer into a kind of system of the most extravagant and inexplicable description. There is neither omnipotence nor omnipresence among the attributes which the last mentioned poet ascribes even to the father of the gods; neither perfect goodness nor perfect happiness in the heaven, which he assigns as their residence. An incomprehensible power, denominated Fate, is represented as directing all events; and it seems to have been the principal office of Jupiter to superintend the execution of its decrees. Idolatry, as denoting the worship of visible objects, was at this period unknown; and even temples appear to have been rare. Prayers were addressed as to invisible deities; and sacrifices, the only duty which they seem to have been considered as expecting from their worshippers, were offered upon altars erected in the open air. A few crimes are sometimes denounced as exposing to the vengeance of the gods, but morality in general finds very little support in the religion of this period. Soothsayers, who professed to foresee future events, were sufficiently numerous; but fixed oracles had not yet attained any extensive celebrity. The salutary doctrine of the immortality of the soul, and a future state of rewards and punishments, was taught in those days; but the ridiculous absurdities, with which it was clothed, tended, when men had learned to despise the fables, to throw contempt also upon the momentous truth which they had veiled. The form of government was monarchical, and in some degree hereditary; but the authority of the kings was extremely limited, and always controuled by established customs. It was the universal prerogative of the prince to exercise the judicial power, to superintend the institutions of religion, to command the armies, and to direct the ordinary business of the community; but, in any extraordinary or very important measure, he was required to consult, not only a council of the principal men, but also an assembly of the people; and a high degree of personal strength and accomplishments seems to have been always necessary to maintain his authority.

It is generally admitted that letters were introduced into Greece from Phœnicia by Cadmus, the founder of Thebes, at the lowest calculation 1045 years before Christ; but it is equally ascertained, that the use of writing had not become common till more than 400 years after his time; and nothing, in the whole history of the ancient Greeks, is more difficult to be explained than the high state of excellence, which the language had attained in the days of Hesiod and Homer, while so little of it could have been reduced to writing. In the absence of letters, poetry seems to have been invented, or at least to have been originally employed for the assistance of memory. Laws, among the early Greeks, were always promulgated in verse, and frequently sung in public. Morality was taught, and history related in the same manner. All, who wished either to instruct or amuse their fellow-citizens, were thus necessarily poets; and they who possessed so important a talent, were considered as sacred characters, favoured and inspired by the gods. The first poetry of the Greeks was uniformly accompanied mith music, and both stringed and wind instruments are mentioned by Homer. But, there are no means of ascertaining its peculiar features; and, however powerful may have been its effects, it appears to have been extremely simple and inartificial in its composition. Their agriculture appears to have been carried on with considerable regularity; and the practice of manuring, as well as ploughing and sowing, is expressly mentioned by Homer. Wine was made from the vine, and oil from the olive; but the principal source of wealth was found in pasturage; and cattle were made, in place of coin, the usual measure of the value of commodities. Commerce was chiefly carried on by an exchange of articles; and the foreign trade of the Grecian cities was principally in the hands of the Phenicians. There were Greeks, indeed, in the days of Homer, who pursued a kind of coasting traffic among themselves; but the profession of a merchant for gain was not held in much estimation, and was less respected than even that of pirate. Their navigation was very imperfect; and they used oars more frequently than sails. Their ships had no decks; and the largest that went to Troy, contained only 120 men. Anchors were unknown; and the vessels, when in port, were either moored to large stones on the shore, or were actually drawn out of the water upon the beach. The early Greeks, in short, were rather boatmen than seamen; and, indeed, to this day, the skill of the navigator is of little avail in their narrow and tempestuous seas. They had little knowledge of astronomy; and marked the length of the year by 12 revolutions of the moon, reckoning the months to consist of 29 and 30 days alternately. But, in progress of time, they learned to fix the seasons more correctly by the rising and setting of the stars; and had arranged them in constellations, much in the same manner, and with the same names as at the present day. They considered internal diseases as inflicted by the immediate hand of the Deity, and as therefore beyond the reach of human skill. Their medical art was thus restricted to the practice of surgery, which was held in high esteem; but which seems to have extended no farther than the extraction of a weapon, or any other extraneous body, from a wound, and the application of a few simples to stop a hæmorrhage, or to assuage inflammation. Their architecture was more improved than most other arts; and Homer speaks of houses built of polished stone, with large and numerous apartments. Other mechanic arts were not exercised as distinct trades; and even princes were frequently their own carpenters. Ornamental works, however, in metals, wood, &c. were not uncommon in those days; but the greater part of the trinkets and more luxurious utensils in use among the early Greeks appear to have been procured from the Phenician merchants. Their principal study, and most constant practice, was the art of war; and they seem to have improved considerably upon that tumultuary warfare, which is generally practised among barbarous nations. Their infantry were commonly heavily armed with helmet, breastplates, greaves, and shield; and were regularly drawn up in close ranks or phalanxes, marching in steady silence under their respective leaders. Cavalry were not yet employed in their battles; but chariots were generally used by the chiefs, as the means of conveying them more rapidly along the line, and of annoying more effectually a flying army. The skirmishing of the commanders, however, in front of the troops, and their mixing with the soldiers in the heat of the fight, left little room for the exercise of generalship; and their fashion of stopping in the midst of the action to strip the slain, sufficiently marks their want of military discipline and skill. They encamped with much regularity, sleeping under their cloaks, or sheltering themselves with huts; and generally fortified their post, when exposed to the attack of a powerful enemy; but, though a small guard might be placed at an outpost, they were unacquainted with the important precaution of stationing and relieving a line of sentinels. In the frequency of war, courage was regarded as the highest virtue; and the manners of the early Greeks were decidedly barbarous. Quarter was rarely granted to a fallen enemy; and the capture of a city was succeeded by the massacre of all the men who were able to bear arms, and by the captivity of the women and children. The spirit of hospitality, however, was generally diffused, and tended often to alleviate the miseries of military devastation. Women appear, as well as men, to have united the highest rank with the humblest occupations, but evidently enjoyed a greater degree of influence and freedom, than has been usual in subsequent ages among oriental nations. There has been supposed to exist, a striking resemblance between the manners and sentiments of the Greeks in the heroic age, and those of the Gothic nations of Europe, except that the latter displayed more generosity in war, and gentleness towards the female sex, than their ancient prototypes.

The period immediately succeeding the Trojan war, affords few lights to history, and is even involved in deeper obscurity than the heroic age. Supposing Homer to have lived within a century, or rather half a century of the Trojan war, his works may be allowed to supply a tolerable record of the previous events best authenticated by tradition, and of the most important occurrences which took place during his own life. His history terminates with the accession of Orestes to the throne of Argos; and total darkness thenceforth rests upon the historian's path, relieved only by a few uncertain glimmerings, till the first Persian invasion of Greece. About 80 years after the destruction of Troy, a great revolution took place, which dissipated ancient traditions, stopped the progress of civilization, and changed the governments, and even the population, of most of the Grecian states. The descendants and partizans of the celebrated Hercules had found a refuge in Doris from the persecutions of Eurystheus; but had never ceased to prefer their claims to the kingdom of Argos, and even to the dominion of all Peloponnesus. Twice had they attempted, without success, to make their way through the isthmus. But, at length, the great grand-son of Hyllus, the oldest son of Hercules, crossed the Corinthian gulf with a powerful armament, and speedily overran the whole peninsula, with the exception of Arcadia and Achaia, where Tisamenus, son of Orestes, made a resolute and successful stand. All the rest of the conquered country was divided among the princes of the Heraclides, and their allies from Doris and Ætolia; and the greater part of the old inhabitants either emigrated from the oppressions to which they were subjected, or were reduced by the invaders to a state of servitude. A new distinction of the Grecian people was the consequence of this revolution. The Pelasgian name, which had prevailed on the continent, and the Lelegian in the islands, had, at an early period, but for reasons not clearly ascertained, given place to the Æolian and Ionian; the latter designation being applied principally to Attica with its colonies, and the former to all the rest of Greece, both within and without the peninsula. Out of these two, four distinctions of the Grecian people arose, after the irruption of the Heraclides. In all the immediate establishments and distant colonies of these invaders, the Doric name and dialect prevailed. The Athenians rose to such pre-eminence, as to give rise to a new designation, namely, the Attic. Excepting them and the Megarians, who retained the Doric name, all the other Greeks, without the isthmus, claimed Æolic origin; and the Ionian name and dialect was retained only by those Ionians who had migrated to Asia and the islands. Except in the rugged province of Arcadia, nothing remained unaltered; and the Dorian invaders brought every thing back to that ruder state, in which they had lived among their native mountains. Disputes soon arose among these allied princes, respecting the partition of the conquered countries. Internal dissensions, occasioned by their turbulent subjects, were continually raging in their respective governments. The enterprising Arcadians seldom suffered them to rest from external hostilities. And, by all these concurring causes, Peloponnesus was rapidly falling back into that state of anarchy and barbarism, in which it had been before the time of Pelops and Hercules. Nothing tended so effectually to resist this tendency to disunion and turbulence, as the revival and regular establishment of the public games, by Iphitus, sovereign of Elis. These athletic games, as is evident from the writings of Homer, had been occasionally celebrated, under the superintendence of different princes; and at the funerals of eminent men, many traditions prevailed, that Eleia in Peloponnesus had frequently been the chosen scene of these contests, and the resort of princes from various parts of Greece. Iphitus, therefore, having procured a favourable response from the oracle at Delphi, established a regular festival for that purpose, to be held every four years at Olympia, in the territory of Elis. Solemn sacrifices were to be offered to Jupiter and Hercules, and games celebrated in honour of these divinities. In these games, all Greeks were free to partake; and, for a certain period, before their commencement, as well as after their conclusion, a general armistice was ordained to take place. The territory of Eleia, particularly, was to be at all times counted sacred, and secured from every hostile encroachment. This Olympian meeting, instituted about half a century after the return of the Heraclides, served as a common capital to the Grecian people, and contributed more effectually than could possibly have been anticipated, to the advancement of arts, science, and civilization, in all the different states. A general revolution in the government of every state, began about the same period to take place, from causes very imperfectly known. The republican spirit, which seems to have existed in all of them, even under their early monarchical constitutions, acquired so much strength, that, in a few ages, monarchy was every where abolished, and the name of tyrant applied to all who attempted its support, even under the mildest form. For a sketch of the peculiar political institutions, and separate history of the several states of Greece, we must refer to their respective names, which form distinct articles in this work, especially to ATHENS and LACEDEMON; and shall, at present, restrict our attention to those more extensive events which affected the Grecian people in general. The first important occurrence of this description, which communicated a new and powerful spring to the genius of the Greeks, and greatly influenced their future progress in every path of art and science, was the unparalleled struggle, which they so long and successfully maintained with the whole power of the Persian empire. See OLYMPIC GAMES.

In the reign of Darius, the son of Hystaspes, the power of the Persian arms was extended on every side of that vast empire. All was subdued to the west, as far as Macedonia. Amyntas, the king of that country, acknowledged subjection to the Persian monarch; and the Grecian islands soon began to feel his ambitious and overwhelming influence. Cyprus, Samos, Lesbios, Chios, and most other islands on the Asiatic coast, were either persuaded or compelled to admit his supremacy. Most of them, according to the uniform policy of the Persians, were nevertheless allowed to retain their own magistrates and laws. One of their own nation was appointed to preside as governor; and this person, whatever was his personal character, was always, from his official situation, denominated Tyrant by the Greeks. Athens itself, hard pressed by the powerful alliance which the Lacedemonians had formed against them, had begun to solicit the protecting aid of Persia; but Artaphernes, satrap at Sardis, having patronised the pretensions of the tyrant Hippias, whom they had driven from his power, they were filled with detestation of the Persian name, and the more readily consented to assist the Ionians in Asia, who had revolted against the authority of Darius. These, however, were speedily reduced; and the Persian monarch, in order to punish Athens and Eretria, who had given aid to the insurgent states of Asia, or rather in prosecution of his ambitious views for the enlargement of his dominions, sent a powerful army into Greece, under the command of his son-in-law Mardonius. Darius had previously dispatched heralds to each of the Grecian states, demanding earth and water as an acknowledgment of his supremacy; and, if wholly independent of each other, the greater part would probably have soon submitted to the Asiatic yoke. But, happily for Greece, its little commonwealths were at that period so united together by reciprocal treaties and obligations, and especially by a formal confederacy under the Lacedemonians, that a kind of general tribunal existed for the punishment of treachery or cowardice, which enabled them, in a great measure, to act as one nation. Macedonia, which had formerly paid homage, was more effectually subdued, and compelled to pay tribute to the Persian king. Thebes, by the influence of a faction, and a few other cities, particularly Ægina, made submission to his demands; but the Lacedemonians and Athenians were so indignant at the requisition of Persia, that, forgetting the law of nations and of humanity, they put the heralds to death with the utmost ignominy and barbarity. The Athenians, who had been at war with the Æginetæ, and were thus the more excited to adopt opposite measures to their hostile neighbours, accused them at Sparta of desertion from the common cause of Greece; and the chief persons of that state were instantly ordered to be seized as traitors to their country. Little progress was made by the invading army. The Persian fleet lost nearly three hundred vessels by a storm in doubling the promontory of Athos; and the land forces suffered so severely from the Brygians, a people of Thrace, that the season for military operations was lost, and the whole armament was led back to winter in Asia. A second army, under the command of Artaphernes, son of the late Satrap of that name, and of Datis, a Median nobleman, avoiding the circuitous march by Thrace and Macedonia, sailed from Cilicia in a numerous fleet, reduced every island and appurtenance of Greece in their way, and approached the frontiers of Attica, with the exiled tyrant Hippias as their guide, before any measures had been concerted by the Greeks for the general security. A messenger was now dispatched from the Athenians to Sparta, with the intelligence of the capture of Eretria, and, at the same time, with a request for assistance to themselves. The Lacedemonians readily promised their utmost aid; but, in conformity to a superstitious law, unworthy of their boasted political wisdom, declared that they could not take the field before the full moon, of which it then wanted five days. Immediate assistance from Sparta being thus denied, it became a question with the ten generals, whom the Athenians had chosen to command their army, whether they should venture to meet the enemy in the field, or apply their whole exertions to prepare for a siege. Opinions were equally divided, and the decision was, by ancient custom, referred to the polemarch Archon, who was persuaded by Miltiades to recommend an immediate engagement; a measure obviously contrary to all principles of defensive war, but rendered necessary by the dread of internal factions in the city. The Persian army, amounting, according to the lowest calculation, (though even that is probably overrated) to 100,000 infantry, and 10,000 cavalry, accustomed to conquer, and having frequently engaged the Greeks of Asia and Cyprus, advanced with confidence as to certain victory. The amount of the Athenian force has been stated as low as 9,000 heavy-armed infantry, and 1,000 Platæans, who had bravely hastened to share the desperate struggle for the freedom of their country. Various considerations,* however, make it probable, that the regular Grecian troops, now opposed to the Persians, were not much less than 20,000, with about an equal number of armed slaves. With this army, still fearfully inferior to the invading host, the genius of Miltiades, who was well acquainted with the nature of the Persian troops, seconded by the determined bravery of his soldiers, gained, on the plain of Marathon, a most decisive victory, and drove the routed Persians to their ships with great slaughter. But this distinguished commander, having failed in a subsequent expedition against the Ægean islands, which had submitted to the Persians, was, by the base machinations of party spirit, condemned to pay a fine of 50 talents, and died in prison of the wounds which he had received.

The death of Darius, the revolt of Egypt, and the disputes which arose about the right of succession to the throne of Persia, procured to the Greeks a respite of several years from any farther attempts against their independence. But Xerxes, the young Persian monarch, was sufficiently ardent to revenge the disgrace which the arms of his nation had sustained, and to prosecute those schemes of conquest which his predecessors had planned. Four years are said to have been employed in preparations for the punishment of Athens, and the reduction of Greece; and an army was collected, more numerous than had ever before, or than has ever since, been known in the annals of the world. To prevent the disasters, which might attend the conveyance of the armament by sea, as well as to provide for the future security of the intended conquest, a canal, navigable for the largest gallies, was, (according to the united testimony of all the Greek historians and geographers,) actually formed across the isthmus, which joins mount Athos to the continent of Thrace. Two bridges of boats also, the one to withstand the winds and the other the current, were extended across the Hellespont nearly between Abydos and Sestos, where the street is about seven furlongs in breadth. Early in the spring, the army

* See a very satisfactory statement in support of this opinion in Mitford's History of Greece.

moved from Sardis, the principal place of rendezvous; and seven days and nights are said to have been occupied in passing the bridges of the Hellespont. The land and sea forces met at Doriscus, near the mouth of the Hebrus, where, according to Herodotus, the Persian monarch reviewed his enormous army, which is said to have been composed of twenty-nine different nations. This historian (whose testimony, as he lived so near the time of the expedition, ought to be most worthy of credit, but whose detail of many incredible concomitant circumstances casts a doubt over his whole narration) estimates the effective strength of the infantry at 1,700 000 fighting men, and the cavalry at 80,000, exclusive of attendants and followers, whose number defied calculation. The fleet consisted of 1207 galleys of war, carrying about 277.600 men; besides transports, store-ships, and a variety of smaller vessels, amounting, at a gross calculation, to 3000, and their crews to 240,000. The land forces marched from Doriscus in three columns, every where adding to their numbers, by compelling the youth of the countries through which they passed, to follow their standards. They met again at Acanthus, where they were joined by the fleet, which then proceeded through the canal of Athos, into the bay of Therme, where the whole army coming up, formed an encampment, extending from Therme and the borders of Mygdonia to the river Haliacmon, near the confines of Thessaly. The Greeks, in the mean time, were slow in concerting any measures for their common defence; and many of the smaller republics readily made the required submission to the Persian monarch, whose sway had been experienced by many Grecian states to be much less oppressive than that of the domineering rule of the Spartan oligarchy, to which the greater part of them had long been subjected. The determined resistance of the Athenian people first arrested the progress of the Asiatic host; and to them chiefly belongs the honour of having preserved Greece from a foreign yoke. To this daring resolution they were prompted, not entirely by the love of freedom, but by the dread of certain punishment. The whole armament was ostensively prepared for their destruction, and their courage therefore was nearly that of despair. Their success at Marathon may have thrown a ray of hope through the gloomy prospect before them; and, at this critical moment, they happily possessed in Themistocles a leader of extraordinary talents, peculiarly fitted for conducting the arduous contest. Deputies from the confederated states at length assembled at Corinth, to consult respecting the conduct of the war; and an attempt was at first made to defend the passes into Thessaly. An army of 10,000 men from the different states, joined by all the Thessalian cavalry, was actually sent to occupy the vale of Tempe; and was competent to have defended the pass against any number of assailants. But the Grecian leaders, alarmed by the accounts which they received of the multitude of their invaders, and understanding that there was another opening into Thessaly, which they did not think themselves strong enough to occupy, were struck with a sudden panic, and, embarking their troops, returned to the Corinthian isthmus; while the Thessalians, now left to their fate, made an immediate submission to the demands of Xerxes. It was next resolved to make a stand at the pass of Thermopylæ, which afforded every possible advantage to an inferior force; but their mutual jealousies and selfish anxiety to reserve their strength for their proper defence, prevented the assembling of a sufficient body of troops; and not more than 4000 men, most of them Arcadian mountaineers, were collected to dispute the passage with the whole Persian army.

Xerxes having halted several days at Therme, to procure proper intelligence and guides, resolved to proceed by Upper Macedonia into Thessaly, and reached the neighbourhood of Thermopylæ without opposition. His fleet, after suffering immense loss by a storm in the bay of Casthanæa, entered the Pelasgian gulf; and the Grecian fleet, which was stationed off Artemisium to support the army at Thermopylæ, succeeded in capturing fifteen galleys, which had been dispersed by the tempest. This favourable event at once revived their spirits, and added greatly to the strength of their little navy. Xerxes, in the mean time, having fixed his head quarters at the town of Trachis, in the Malian plain, waited four days, in expectation that the Greeks would yield to his numbers, and leave him an uninterrupted passage. A herald also was dispatched to Leonidas, who commanded at Thermopylæ, requiring him to deliver up his arms; to whom the Spartan replied, with laconic brevity, "Come and take them." The Persian monarch, therefore, on the fifth day, ordered the Medes and Cissians of his army to bring Leonidas and his Greeks into his presence. These being quickly repulsed, the Persian guards, called "the immortal band," were marched to the attack. Their numbers were unavailing on so narrow a field; their short spears were very inferior in close fight to the longer weapons of the Greeks; and their repeated and courageous efforts, to which Herodotus bears ample testimony, made no impression. The assault was renewed on the following day, in hopes that wounds and fatigue might exhaust the little army of the Greeks; but still without the smallest prospect of success. A Persian detachment, however, having penetrated during the night by another pass, and surprised the Phocians, who had been intrusted with its defence, shewed themselves, on the morning of the third day, far in the rear of the Grecian army. Information of this fatal advantage being conveyed to Leonidas, it was immediately resolved that they should all retreat to their respective cities, and preserve their lives for the future wants of their country. Leonidas, however, in obedience to a law of Sparta, which forbade its soldiers, under whatever disadvantage, to flee from an enemy, resolved to devote his life to the honour and service of his country. Animated by his example, every Lacedemonian and Thespian under his command, determined with him to abide the event. The Thebans also, on account of the disaffection of their city to the Grecian cause, were detained, rather indeed as hostages than as auxiliaries.* Leonidas stationed his little band at the wall of Thermopylæ, where the pass was scarcely 50 feet wide; and all of them resolved to sell their lives to the enemy at the dearest rate. With the fury of men resolved to die, they rushed against the advance of the Persian army, and made a dreadful slaughter of the crowded and ill-disciplined multitude. Numbers of them were forced into the sea, and many of them expired under the pressure of their own people. Leonidas fell early in the fight, at the head of his troops; but the engagement was continued, with advantage on the side of the Greeks, till the Persian detachment came in sight of their rear. They then retreated to the narrowest part of the pass, where the Thebans began to sue for mercy, and were most of them taken prisoners. The surviving Lacedemonians and Thespians gained a little rising ground, where they fought in the midst of a surrounding host, till they were utterly cut to pieces. In the conduct of the Spartan prince, there was wisdom as well as magnanimity. His example checked the disposition which prevailed among the Greeks, to shrink from the Persian power; and gave a convincing proof to the invaders, at

* In the army at Thermopylæ there were originally 300 Lacedemonians, 700 Thespians, and 400 Thebans.

how vast a price of blood they would purchase their conquest. During their trancactions at Thermopylæ, the Grecian fleet gained several advantages over that of the Persians; and about two hundred galleys of the latter, attempting to take the Greeks in the rear by sailing round Eubœa, were totally lost in a storm. Having received intelligence of the fall of Leonidas, and the retreat of the rest of the army, the Grecian fleet retreated from Artemisium, and sought the interior seas of Greece. The Persian army experienced no opposition in their march through Doris and Bœotia, which, excepting the cities of Thespiæ and Platæa, had always been adverse to the confederacy of Greeks. Phocis alone, of all the provinces between Thessaly and the isthmus, remained faithful to the cause of the Grecian independence. Its territories, therefore, were ravaged without mercy by detachments of the enemy; while the main body advanced in a direct course to the devoted city of Athens. The Peloponnesian troops having resolved to confine their operations to the defence of the peninsula, Attica was completely abandoned to the whole weight of the invading host. Athens was filled with alarm, and all were convinced that their destruction was inevitable. The oracle at Delphi, however, having recently pronounced, that "the wooden wall" alone would afford an impregnable refuge to themselves and their children, Themistocles, who had probably himself suggested the response, persuaded his countrymen that they were thus directed to embark on board their fleet. Their families and effects were, in conformity to his advice, immediately transported to Salamis, Ægina, and Træzene; and all the males who were able to bear arms repaired to the ships. A few of the poorer citizens, who were unable to bear the expence of a removal, and some others, who conceived the answer of the oracle to point out their citadel, which was built of wood, as the place of safety, refused to abandon the city. The Persian army, advancing from Thebes, burned the forsaken cities of Thespiæ and Platæa; and experienced no resistance till they reached the citadel of Athens, which was immediately invested; and, being taken by assault, all within its gates were put to the sword. The commanders of the Grecian fleet, which was now assembled in the bay of Salamis, alarmed by the intelligence of the fall of Athens, had resolved in a council of war to retreat without delay, when Themistocles, addressing Eurybiades the Lacedemonian, who had the chief command, threatened, if such a resolution were adopted, to withdraw the whole of the Athenian ships, which composed nearly one-half of the allied fleet, and either to make peace with the enemy, or seek some distant settlement for his deserted people. His advice prevailed, and it was determined to await the approach of the enemy in the straits of Salamis. This Athenian chief, however, still fearful lest some of the squadrons should depart, is said to have accelerated the approach of the Persians, by causing their monarch to be privately informed, that the Greeks were planning a retreat, and that he would thus lose the most favourable opportunity of destroying their whole navy at one blow. His stratagem was attended with entire success. The Persian fleet hastened to make a general attack; while their army lined the adjacent shores, and their monarch himself was seated upon an eminence to view the approaching battle. His fleet amounted to 1200 galleys, and that of the confederated Greeks to 300; but the narrow strait prevented the numerous ships of the Persians from being regularly brought into action, and the crowded situation rendered it impossible for the Phenician squadron to avail themselves of the superior swiftness of their galleys, and skill of their seamen. The very zeal of the Persian commanders to distinguish themselves in the presence of their monarch, tended to increase the confusion. The resolute and persevering attacks of the Greeks, aided by the united talents of Themistocles and Aristides, allowed not a moment's respite to the enemy to restore order, or recover from alarm. The confusion soon became so general, that even flight was impracticable, and the sea itself (according to the description of the scene by the poet Æschylus, who fought on board the Athenian fleet) became scarcely visible from the quantity of wreck and corpses floating on its surface. Forty Grecian galleys are said to have been sunk or destroyed; but most of the crews saved themselves on board of the other ships, or on the neighbouring shore of Salamis. But the Persians had no refuge; and their defeat was attended with immense loss. Still the remains of their fleet were so large, that the principal port of Attica could not admit half its numbers; and the Greeks were expecting a renewal of the action on the following day. But the Persian commanders appear to have concerted no measures on the supposition of a retreat; and a hasty order during the night, directed the whole fleet to steer immediately for the Hellespont. The army, thus destitute of the supplies derived from the ships, and unprovided with sufficient magazines on land, fell back upon the friendly province of Bœotia, and speedily retreated into Thessaly. Three hundred thousand men were chosen to remain, under the command of Mardonius, to complete the conquest of Greece in the following summer. Of this number, 60,000 of the best troops were selected as a royal guard, to accompany their monarch as far as the Hellespont on his return to Persia. The rest of the immense multitude which he had led into Greece, left to their own resources, suffered beyond description, from the haste of their march, and the want of magazines. They subsisted by rapine from friends as well as foes; and were reduced at last to eat the very grass from the ground, and the bark from the trees. Disease destroyed whom famine had spared; and the towns of Thessaly, Macedonia, and Thrace, were crowded with the sick and the dying. Upon reaching the Hellespont, the bridges were found to have been destroyed by the violence of the current and the storms; but the fleet had arrived to transport the wretched remains of the Persian host; and its discomfited monarch proceeded to Sardis, not indeed entirely unattended, as some of the Greek historians relate, but with such a diminished retinue as might almost be called nothing, when compared with the incalculable numbers who formerly surrounded his person, and obeyed his command.

Early in the following spring, the Persian fleet assembled at Samos, and Mardonius, having attempted without success to detach the Athenians from the Grecian confederacy, compelled them again hastily to abandon their country; and, without opposition, regained possession of Athens. The Athenian people, under the protection of their fleet, withdrew to Salimas; and there, though deprived of their country, and disappointed of the timely assistance which they ought to have received from the Peloponnesian states, still rejected, with the most enthusiastic magnanimity, all the conciliatory proposals of Persia. The Lacedemonians, who were at the head of the allies, at length ashamed of their ungenerous and dastardly delays, dispatched an army of 5000 Spartans and 35,000 Helots, under the command of Pausanias. These were joined at the isthmus by the other Peloponnesian troops, and by the Athenian army under Aristides. Mardonius, secretly apprized of their march, gave up the city of Athens and its surrounding territories to be pillaged by his troops, and fell back upon his magazines in Bœotia, where he extended his camp along the course of the Asopus to the frontiers of Platæa. The confederated Greeks, animated by the propitious omens which had been indicated at their solemn sacrifices, advanced with confidence to meet the Persians, and pitched their camp at the foot of Mount Cithæron, on the opposite side of the river Asopus, composing a force of 110,000 men. Mardonius, who appears from the account given by Herodotus (the most impartial historian of the Persian invasion) to have been deficient neither in courage or policy, anxious to draw the Greeks from their advantageous position, harassed them greatly with incessant charges by his cavalry; and more than ten days were spent in various evolutions, on both sides, to gain the superiority of the ground, and to induce each other to commence the attack. In one of these movements, the greater part of the Grecian troops, excepting only the Tegeans, Lacedemonians, and Athenians, actually fled to the walls of Platæa; and the Persian commander, imagining the retreat to be general, hastily advanced with his infantry as to certain victory. A fierce engagement ensued, in which the Persian soldiers, though insufficiently armed for close fight, and unequal to the Greeks in the practice of war, discovered no inferiority in point of courage and enterprise; and were often seen, in their vigorous assaults, seizing and breaking with their hands the long spears of their opponents. Multitudes perished in these vain attempts to penetrate the Spartan phalanx. Their efforts, after repeated failures, began to relax. The Greeks advanced in their turn; and confusion soon became general among the Persian infantry. Their commander Mardonius, while leading on a chosen body of cavalry to support his broken troops, received a mortal wound; and his fall was the signal for flight to the whole Persian army. Artabazus, next in command, who is said to have dissented from his general in the conduct of the battle, as soon as he was assured of the rout of the main body, retreated with 40,000 men towards Phocis; but the Persian and Bœotian cavalry still kept the field, and afforded considerable protection to the flying infantry. The Lacedemonians and Athenians, however, having succeeded in carrying the Persian camp by assault, a dreadful slaughter ensued; and excepting the detachment which had escaped under Artabazus, only 3,000 finally survived of 260,000 Asiatics, who composed the rest of the army of Mardonius. In the mean time, the Grecian fleet, which had remained during the summer inactive at Delos, was encouraged, by a private assurance of the favourable disposition of the Ionians, to attack the Persian fleet at Samos. The Persian admiral, having suffered the Phenician squadron to depart, in the idea that the season was too far advanced for naval operations, as soon as he received intelligence of the approach of the Greeks, hastily sailed from Samos; and, passing to the opposite promontory of Mycale, drew his galleys upon the beach, and prepared to defend them on shore. The Greeks, resolving to attack the fortified camp, disembarked their forces in two divisions, one under the command of Xanthippus the Athenian, and the other led by Leotychides the Lacedemonian. The former arriving first at the Persian entrenchments, immediately commenced the assault; and, aided by the Greeks in the Persian service, had entered the rampart, before the Lacedemonians came up. The other Asiatics instantly fled from the Athenian assailants; but the native Persians resisted with the utmost bravery, till the arrival of the Lacedemonians, when they were completely overpowered, and almost entirely cut to pieces. The victorious Greeks, after carrying off the most valuable part of the spoil, set fire to the camp, and consumed the whole of the Persian fleet on the very same day that their army was annihilated at Platæa. This successful resistance of Greece to the Persian invasion holds out an encouraging example to all free states, to maintain their independency against any power, however formidable; and clearly shews, that an obstinate determination never to submit, accompanied with wise counsels and steady discipline, will rarely fail of ultimate success. The Persian war, indeed, was not yet terminated. The Greeks, in their turn, became the assailants and invaders. They prepared to protect the Ionians, who had thrown off the Persian yoke, and particularly to restore freedom to those Grecian cities in which the Persians had left garrisons. Under the Spartan general Pausanias, but especially under Cimon the Athenian, they carried their victorious arms to Byzantium, to the island of Cyprus, and even into Egypt. By a double victory gained on the river Eurymedon, under the last mentioned commander, both over the fleet and army of Persia on the same day, its naval strength was so broken, and its land forces so disheartened, that offensive operations against Greece were totally intermitted; and it became the boast of the Grecian states, that no armed ship of Persia was to be seen westward of the Chelidonian islands, or the entrance of the Euxine, and that no Persian troops dared to shew themselves within a day's journey of the Grecian seas. But the ambitious views and political jealousies which arose among the confederated states of Greece, during the prosecution of these successful operations, prepared greater evils for their country than all that they had endured, while struggling under the pressure of the Persian hosts. The Athenians, though apparently the greatest sufferers by the invasion, derived the greatest benefits from its effects. They found their country laid waste, and their city in ruins; but, in consequence chiefly of their naval superiority, and a succession of great commanders, they rapidly attained that supremacy in Greece, which the Lacedemonians had hitherto enjoyed; and by the able conduct of Cimon, the most distinguished of all their leaders, soon reached the summit of their political influence and military power. The Lacedemonians had not been inattentive observers or inactive opponents of the growing consequence of the rival state; but, usually slow in their counsels, (and weakened by an earthquake which laid their capital in ruins, and by a consequent insurrection of the Helots, which reduced them to the necessity of requiring aid from their neighbours,) had long evaded an open rupture with the Athenian republic. The latter people, however, accustomed to war, elated with success, swayed by a turbulent democracy, and unable longer to disguise their ambitious designs upon the liberties of Greece, not satisfied with repeated interferences and aggressions against the ancient allies of Lacedemon, proceeded at length to make a direct and unjustifiable attack upon its armies, while returning from the protection of Doris, against the inroads of the Phocians. Aided by the Argians and Thessalians, they met the Lacedemonians and their Peloponnesian allies at Tanagra in Bœotia. After a severe action of two days, and great slaughter on both sides, the Athenians were compelled to retreat, and the Spartans pursued their march without farther obstruction.

In the view, however, of raising a state without the peninsula, to balance the power and curb the ambition of Athens, they formed a close alliance with the Thebans, and willingly seconded their attempt to recover that supremacy in Bœotia, which they had been accustomed to claim before the event of the Persian war. But the Athenians under Myronides speedily regained the influence which they had lost by their defeat at Tanagra; and all Bœotia, with the exception of Thebes, was brought either into their alliance, or under their dominion. Burdened at length by the variety of their military operations, and even by the extent of their conquests, they were disposed to enter into negotiations with their Peloponnesian adversaries; and by the good offices of Cimon, whom they recalled from exile, and who had always been greatly esteemed at Lacedemon, a truce for five years was concluded between the rival powers. But after the death of that distinguished commander, who had uniformly exerted himself to divert the military spirit of the Greeks from internal wars, hostilities were again renewed. The Athenians, however, being hard pressed, and even invaded by the Peloponnesian confederates, as well as encumbered by the numerous islands and colonies subject to their empire, a second time sought an accommodation; and a truce was concluded for the space of thirty years, upon terms by no means advantageous to their influence. But the constitution of Greece, composed of so many small and independent states, was unfavourable to a long continuance of general tranquillity. Its governments were so distinct, that no common authority could prevent the occurrence of partial wars; and yet so connected, that war in any part always endangered the peace of the whole. This was more especially the consequence of a practice, which had become universal among the weaker states, to provide for their protection by courting the alliance, or rather acknowledging the dominion, of one of the two leading republics of Lacedemon or Athens. These two rival powers also differed considerably in the political principles which they respectively favoured, the former being generally the patroness of aristocracy, and the latter of democracy. Hence their influence was extended, according as one or other of these opposite factions prevailed in the different states; or rather, according as their arms were severally crowned with success, the party to which they were friendly gained the ascendency, and succeeded in bringing the state which it ruled to the side of Sparta or of Athens. This constant rivalship, never wholly dormant, and kept in continual excitement by the frequent quarrels of the minor commonwealths, at length gave rise to the long and bloody contest of the Peloponnesian war. The Athenians, having assisted the Corcyræans against the Corinthians, were formally accused by the latter people, joined by many other complainants, of having broken the truce, and insulted the Peloponnesian confederacy. An assembly of deputies from the different states, of which that confederacy was composed, having met at Sparta, a great majority decided for an immediate recourse to arms; and even the historian Thucydides admits, in the most explicit terms, that a general sentiment of indignation had been excited among a large portion of the Grecian people, by the arbitrary and oppressive sway of the Athenian republic. See Aristides, &c.

The two hostile confederacies, though very differently composed, divided between them very equally the force of the Greek nation. All the Peloponnesian states, except the Argians, who remained neutral, joined the Lacedemonians. In Northern Greece, the Megarians, Bœotians, Locrians, Phocians, &c. formed a part of the same alliance; and external assistance was expected from the king of Persia, and the Grecian colonies of Italy and Sicily. The Athenians had a few allies, and some of them not very zealously inclined to their cause. The principal were the Thessalians, and Acarnanians, and the islands of Corcyra, Zacinthus, Chios, and Lesbos. But all the other islands of the Ægean Sea, except Melos and Thera, and all the wealthy Grecian cities of Thrace, of the Hellespont, and of Asia Minor, were tributary subjects of Athens, and entirely subject to its controul. The Spartan king Archidamus, who had the chief command of the Peloponnesian forces, amounting to 60,000 men, advanced slowly to the invasion of Attica; but, before actually commencing hostilities, he once more proposed the terms of accommodation, which the Athenians had formerly rejected. The celebrated Pericles, who had long directed the councils of Athens, and who is supposed to have plunged his country into war, for the purpose of prolonging his personal influence in the state, easily induced his fellow citizens to refuse all farther negociation; but all his extraordinary talents were necessary to persuade the Athenian people to adopt measures of defence, to which they were reduced by the power of their enemies. Abandoning their country to the ravages of the hostile army, they were compelled to secure themselves and their effects within the walls of the metropolis, filling the temples, the turrets of the ramparts, the tombs even, and the lowest hovels, with their wives and children. Pericles, reproached and threatened as the principal author of their calamities, and vehemently urged to meet the invaders in the field, directed all his attention to the defence of the city and the preservation of good order. The Lacedemonians and their allies, having exhausted the means of subsistence, and loaded themselves with plunder, returned to Peloponnesus, and dispersed to their respective cities. The Athenian fleet, in the mean time, ravaged the coasts of Peloponnesus, taking, in its return, the island of Ægina; and, towards the end of autumn, Pericles, with the whole of the land forces, laid waste the neighbouring territory of Megara. At the commencement of the second summer, the confederates under Archidamus again entered and ravaged the country of Attica; while a more dreadful scourge, a pestilential fever, resembling the modern disease of the plague, raged in the crowded streets of the city. The war, however, was not arrested by this awful calamity; and, for several years, was regularly conducted in the same manner. The Peloponnesian states were so superior in land forces, that they annually invaded the territories of the Athenians, who could not risk a general action without exposing themselves to certain ruin; yet the confederates were, on the other hand, so ignorant of the art of attacking fortified places, that they could make no impression upon a city like Athens, defended by 30,000 men, and supplied by a powerful fleet. The war thus continued to rage, for many years, with nearly the same success, and equal losses on both sides. It consisted in a succession of partial engagements, hasty excursions, and distant sieges, which never affected the main object in view, or brought the contest one step nearer to a conclusion. Partaking also in a great degree of the nature of a civil war, it was carried on with a spirit of ferocity rarely exemplified among civilized nations; and, though the time of its continuance, the very age of Socrates himself, was an era, at least in the history of Athens, characterised by the high perfection to which arts and sciences, philosophy and refinement, had been brought; yet, in no period of Grecian history, were more atrocious barbarities committed. Every transaction has been minutely recorded by the Athenian historians, Thucydides and Xenophon, who were contemporary with most of the events which they describe; and our account must be greatly compressed, not from the scarcity, but from the abundance of materials. The league, headed by the Athenians, was almost entirely under their command; while that of Peloponnesus, being composed of independent states, was continually changing in its component parts, and liable every instant to be utterly dissolved. Had the Athenian people therefore steadily adhered to the plan of Pericles, and, renouncing every idea of conquest, confined themselves to a defensive war by land, and offensive operations by sea, they might ultimately have triumphed over their numerous opponents; and, at least, have inflicted more serious injuries than they could have received. From the excessive diversity and disproportion of the forces engaged in the contest, the one over-running the land, and the other scouring the seas and coasts, the war was inevitably spun out to an indefinite length; and often were both parties, wearied of their accumulated sufferings, desirous of peace; but proposals for negociation were as often prevented by the vain ambition of Cleon, who had succeeded, at the death of Pericles, to the direction of the Athenian councils, and by the warlike spirit of Brasidas, the bravest of the Spartan leaders. After their death, a truce was concluded for the space of fifty years; and every thing was restored to the same situation in which it had stood at the commencement of hostilities: but mutual hatred, and boundless ambition, had acquired such hold of the minds of the principal men on all sides, that the appearance of concord was of short duration. New leagues and dissensions arose, which led to reciprocal recriminations and partial hostilities; but it was not till the expiration of nearly seven years, that they again came to an open rupture. Athens was the aggressor, and the ambition of Alcibiades was the sole cause of the renewal of hostilities. This celebrated character, with all his accomplishments and talents, was guided by principles so inveterately vicious, that he alone may be charged with having accelerated the ruin of the Athenian state, and completed the corruption of its citizens. He persuaded the people, without any other reason, except that the city Egesta in Sicily had solicited the assistance of the Athenians to undertake the conquest of that island; but, scarcely had the expedition, in which he was appointed a commander, commenced its operations, when he was recalled to stand his trial upon a charge of impiety. Aware of the caprices of his countrymen, he took refuge in Peloponnesus; and, enraged by the sentences pronounced against him in his absence, he instigated the Lacedemonians to assist the Syracusans, and to attack the Athenians, while their army was engaged in the remote and romantic enterprize which himself had planned. The Sicilian expedition terminated in the most disastrous manner; and almost the whole of the Athenian army was destroyed or taken captive. The Lacedemonians, supported by a powerful confederacy, and assisted even by the Persian viceroys, invaded Attica, blockaded the city of Athens, and would speedily have terminated the war by its reduction. But Alcibiades, having been expelled from Sparta on account of his licentious practices, exerted himself to detach their Persian allies, and to retrieve the falling hopes of his country. Recalled by the army, and raised to the chief command by the unanimous acclamations of the people, he recovered many of the lost colonies, defeated the fleet of the confederates, and so alarmed the Lacedemonians, that they were ready to have treated for peace. But the Athenians, intoxicated with success, prolonged the war; and, insensible to their interest, again threw away the instrument of their victories. Their fleet having sustained a trifling loss while Alcibiades was absent, and employed in levying contributions in Ionia, for the support of his forces, he was instantly disgraced by the fickle voice of the populace; and the power of Peloponnesus again acquired the ascendancy. The confederates, taught by experience, had exerted themselves to increase the number of their ships, and had at length succeeded in attaining also a portion of that maritime skill, which had hitherto given to the Athenians so decided a superiority by sea. The Athenian navy, however, trusting to their long acknowledged eminence, and elated by a victory which they had gained over the Spartan fleet at Arginusa, near Lesbos, despised their enemies, and neglected all ordinary precautions, with unexampled imprudence. Lysander, the ablest of the Lacedemonian generals, having succeeded to the command of the allied fleet, and taken the city of Lampsacus upon the coast of the Hellespont, resolved to avail himself of that self-confidence which guided the councils of the Athenian captains. In order to increase their insolent security, he repeatedly declined battle, which they daily offered him, but kept his own crew prepared for action at a moment's warning. Having learned that they regularly drew their fleet ashore on the open beach at Aigospotami, on the opposite coast, not more than two miles from his own station, and then suffered the soldiers and crews to disperse over the adjoining country in quest of lodgings and provisions; he easily found means to surprise them in this unguarded condition, made himself master of their whole fleet except nine galleys, and took prisoners the greater part of their forces, by which it had been manned. A striking instance now occurred of that savage barbarity, with which the different powers in the Peloponnesian war were generally chargeable. The Athenians had resolved, in their assurance of victory, to cut off the right hand of every prisoner whom they should capture; and this intended cruelty, with many similar acts which they had perpetrated, was immediately requited by a general massacre of the captives at Aigospotami. Lysander, with his own hand, cut down their general Philocles, after reproaching him with having first set the example among the Greeks of such violations of the laws of war; and, upon this signal, about 3000 Athenian citizens were butchered in cold blood, by the allied troops. The Lacedemonian commander, now completely master of the seas, speedily reduced the principal colonies and dependencies of Athens; and then hastened, with a fleet of 200 galleys, to blockade the port of that devoted city, while the land forces of the confederates, at the same time, surrounded its walls. No assault was attempted, and its reduction was left entirely to the sure operation of famine. The haughty and turbulent citizens discovered not even the courage of despair in their defence; but were solely anxious to avert the sentence of utter extermination, with which they were threatened by some of the allied states. The Lacedemonians, however, probably as much from policy as generosity, secured for them more favourable terms, and saved their persons from servitude and slaughter. But it was determined, as a measure absolutely necessary to the safety and repose of Greece, that their tyrannical spirit should be effectually humbled, and their power as a state entirely broken. They were spared upon the following conditions; that all their ships of war should be surrendered, except 12; that the long walls and the fortifications of Peiræus should be destroyed; that all exiles and fugitives should be restored to the rights of the city; that the Athenians should hold always as friends or enemies those states, who were the allies or the adversaries of Lacedemon; and should be ready to attend the Spartan power, by sea or land, as they might receive orders. These terms being accepted, the Spartan fleet entered the Peiræus, and the army took possession of the walls. The fortifications, which had been condemned, were instantly thrown down, to the sound of military music, and their demolition celebrated with triumph as an æra of recovered freedom to Greece. The popular assembly was abolished; the government changed from democracy to oligarchy; and thirty magistrates were appointed to form the new administration of the commonwealth. Such was the termination of the Peloponnesian war, in its twenty-seventh year; and Lacedemon, now in alliance with Persia, having again become the leading power in Greece, the aristocratical interest reigned paramount in almost every Grecian state. See Alcibiades, &c.

Sparta, having recovered her influence in Greece, acted not less tyrannically than on former occasions; and, under the ambitious projects of Lysander, became daily more corrupted in her principles of policy. The thirty magistrates, who had been placed at the head of the Athenian state, were supported by assistance from Lacedemon in the most attrocious acts of cruelty and injustice; and the other Grecian cities were prohibited even to afford a refuge to the unhappy Athenians, who fled from their oppressors. Not contented with cutting off their political adversaries, the thirty tyrants, under the direction of Critias, proceeded to murder, upon frivolous pretences, all persons whose riches they wished to sieze; and the slightest murmur against their oppressions was punished with imprisonment, exile, or death. In the space of eight months, fifteen hundred citizens were sacrificed to their avarice or vengeance; and Xenophon goes so far as to affirm, that their short reign was more destructive to Athens, than the preceding war of thirty years. At length, however, Thrasybulus, at the head of his exiled countrymen, drove the tyrants from their seat of abused power, and restored the ancient democratical form of government at Athens. By his wise moderation the spirit of retaliation was restrained, a general amnesty proclaimed, and tranquillity restored to the Athenian state. But whatever was the form, tyranny was too generally the spirit of the Grecian governments, and especially of the pure democracy at Athens. Equally unjust and cruel as the most lawless despots, they were often much more inconsistent with themselves, and fickle in their proceedings. While they allowed their poets, for their amusement, to ridicule the gods upon the stage, they punished their sages, who endeavoured, for their instruction, to introduce worthier sentiments of religion. By their sentence, the celebrated Socrates, (whom even the thirty tyrants had spared, though he often opposed their measures,) was iniquitously put to death.

The Greeks were again involved in a contest with Persia, by the attempt of Cyrus the younger to dethrone his brother Artaxerxes. That ambitious prince being governor of Asia Minor, and friendly to the Spartans, persuaded them to join his standard with 13,000 Grecian troops; but, excepting their leader Clearchus, they are said to have been entirely ignorant of his views upon the Persian crown. The celebrated retreat of the remains of this army, after the death of Cyrus, generally called the retreat of the ten thousand, is considered as one of the most extraordinary exploits recorded in the annals of the military art; and, by proving the weakness of Persia, is supposed to have had considerable influence in promoting the Macedonian invasion, and conquest of that extensive but feeble empire. It had the more immediate effect of encouraging an expedition, under Agesilaus king of Sparta, to recover the liberty of the Grecian colonies in Asia. Assisted by 30 captains, with Lysander at their head, he filled all Asia with a dread of his arms; and was preparing to carry the war into the heart of the empire, when he was suddenly recalled for the protection of his own country. The Persian monarchs had discovered a more easy and effectual defence against Grecian valour, than their most numerous armies had been able to provide; and, by a seasonable distribution of bribes among the leading men of the different states, succeeded in turning the arms of these warlike republics against one another. The Thebans were first gained to their interests, who easily succeeded in persuading the Athenians. Even Argos and Corinth, two Peloponnesian states, joined the confederacy, to which were added Acarnania, Ambracia, Leucadia, Eubœa, part of Thessaly, and Chalcidice in Thrace. The haughty tyranny of Lacedemon furnished sufficiently ostensible reasons for the union; and Persian gold readily supplied the arguments which were wanting. The confederates sustained a severe check in the vicinity of Corinth, and were afterwards defeated by Agesilaus at Coroneia, with great loss on both sides; but Pharnabazus, assisted by the Athenian commander Conon, having defeated the Lacedemonian fleet, completely destroyed their influence in Asiatic Greece. They proceeded even to ravage the coasts of Laconia; and, assisting the Athenians to rebuild their long walls, which connected the Peiræus with the city, again laid the foundation of their naval power. After various vicissitudes and intrigues, all parties became tired of war, and disposed to peace. The Lacedemonians, though still superior in the field, yet destitute of the aid which they had formerly derived from the Persian treasury, were straitened in their pecuniary resources; and Pharnabazus, the friend of Athens, having been succeeded in Lydia by Teribazus, the new Satrap became favourable to the interests of Sparta. By the able negociations of Antalcidas the Lacedemonian, the Persian monarch was brought in as mediator, or rather dictator, for a general pacification among the states of Greece, of which the conditions were simply these; "that all cities on the continent of Asia, together with the islands of Clazomene and Cyprus, should belong to the Persian empire; and that all other Grecian cities, small and great, should be completely independent, except that the islands of Lemnos, Imbros, and Sciros, should remain as formerly under the dominion of Athens." Against all who should refuse these terms, the court of Persia declared itself ready to unite with those who accepted them, and to render every assistance, by land and sea, to reduce the refractory. The weaker states were well pleased to be secured in their independence. The Athenians were gratified by the exception in their favour. The Thebans, anxious to preserve their authority over the smaller towns of Bœotia, wished to stipulate for that superiority; but were compelled to concur in the terms. And the Lacedemonians, while they lost nothing by abandoning the Asiatic Greeks, whom they had already been obliged to desert, gained the great object of the war,—the separation of the states which had combined against them, and the emancipation, especially, of the Bœotians from the growing power of Thebes. They soon shewed that they accounted themselves to have established their supremacy; and were the first to disturb the general tranquillity. They demolished the fortifications of Mantinæa, as a punishment for the disaffection of its citizens to the Lacedemonian interests, during the preceding wars. They marched against Olynthus, a Grecian city of Thrace, because, by associating the smaller towns in its vicinity under one government, it was considered as infringing the conditions of the late treaty; though its only offence was the increase of its strength by a wise and liberal policy, which ought to have been emulated, rather than opposed by the other Greeks. They interfered also, in the most unjustifiable manner, in the political contests which agitated the Theban state; and, by this rash measure, gave rise to a long and complicated struggle, which ended only with the general overthrow of Grecian independence. Their general Phæbidas, returning from an expedition against the Olynthians, was persuaded to join the leader of the aristocratical party in Thebes, and to occupy the citadel with a Lacedemonian garrison. This unauthorised step, though at first disapproved by the government of Sparta, was finally sanctioned, by their retaining possession of the fortress thus treacherously seized, and by their bringing to trial and punishment the chief of the adverse faction, as if they had been the constituted judges of Thebes. For the space of four years, they succeeded in holding the Thebans under the most humiliating subjection; but suddenly the Theban exiles, with the assistance of the Athenians, by one of the boldest and best conducted exploits recorded in history, recovered possession of their power in the city, and compelled the Lacedemonians to evacuate the citadel. With difficulty the Thebans at first withstood the armies of Sparta, by acting on the defensive; but gradually improving in military skill, they learned to face in the field, and to combat, even with inferior numbers, the experienced troops of their powerful adversary. Under the able direction of Epaminondas and Pelopidas, they ventured, though then without an ally, to persevere in the unequal contest; and, in the famous battle of Leuctra, the bloodiest action hitherto known in Greece, these distinguished commanders, by their skilful dispositions, and the enthusiastic courage with which they inspired their troops, defeated an army nearly four times the number of their own. Never had the Lacedemonians, before that day, retreated from an inferior force, or lost in any one engagement so many of their citizens. Another of their boasts, "that never had the women of Sparta beheld the smoke of an enemy's camp," was now also done away.

The victorious Thebans, headed by Epaminondas, and joined by many of the Grecian states, ravaged the Lacedemonian territories to the very suburbs of the capital; and on their return reinstated the Messenians, whom the Spartans had driven from their country. The Lacedemonians, alarmed not merely for their supremacy but their safety, secured assistance from Athens, from Syracuse, and even from Persia, while the Thebans were hard pressed by a war in Thessaly, against Alexander, tyrant of Pheræ. Pelopidas, however, having been dispatched to the Persian court, succeeded in recommending himself to the esteem of the monarch, and in turning his friendship to a state which had never been at war with Persia. Thebes, intoxicated with her rising power, which she owed chiefly to the abilities of her leaders, obstinate in maintaining her authority over the cities of Bœotia, which was perhaps necessary for her resistance to Lacedemon, and aiming to become the arbitress of Greece, which her sudden elevation provoked many of the states to regard as unpardonable presumption, may be considered as at this period the cause of the continuation of hostilities among the Greeks. Sparta, however, was equally obstinate in refusing to acknowledge the independence of the Messenians, and war was prolonged for some time with little effect, chiefly between the confederates of the two principal powers. The Thebans, having at length terminated the war with Thessaly, with the loss of their able general Pelopidas, were at liberty to take part more effectually in the transactions of Peloponnesus. A civil war having broken out in Arcadia between the cities of Mantinæa and Tegea, the Thebans supported the cause of the latter, while the Athenians and Lacedemonians declared for the former. The very existence of Sparta was threatened by the bold and enterprising measures of Epaminondas, who had nearly taken the city by surprise; but, frustrated in his plan by the activity of Agesilaus, he returned and gave battle to the Lacedemonians and their allies at Mantinæa, where he was mortally wounded in the moment of victory, and where with him the power of the Theban state expired. A general pacification succeeded, upon the basis of the former treaties prescribed by Persia, that every city should be independent; but the Lacedemonians still persisting in their wish to reduce the emancipated Messenians, were excluded from the treaty, and remained nominally at war with the confederates of Thebes. Exasperated by the friendly dispositions which the Persian court had manifested to the Thebans, and perhaps expecting to acquire some pecuniary resources for the recovery of their power in Greece, they sent an army to aid the insurgents in Egypt. After the death of Agesilaus, on his return from Africa, little occurs in the history of Greece deserving of notice, till the appearance of Philip of Macedon. A great change had taken place in Grecian politics. There was now no leading state, either of the aristocratical or democratical interests; and, though every city exercised a jealous watchfulness to prevent any overbearing superiority in another, there were no extensive confederacies or hostilities; but lassitude, indecision, and divisions, pervaded the nation, and paved the way for the universal subjugation of their liberties by the Macedonian monarchy. See Agesilaus, Epaminondas, &c.

In consequence of the blow given to the Spartan power in the battle of Mantinæa, and the decline of Thebes after the loss of Epaminondas, Athens remained the most prominent and respected of the Grecian republics. In want, however, of any salutary check from a powerful rival, its government became extravagant and irregular in the most extraordinary degree; the inconsiderate voice of the multitude deciding every measure, frequently ratifying at night what they had rejected in the morning, and ready to follow every varying scheme of every flattering orator. The citizens also, sinking into unbounded luxury, declined all military service, and resorting to the aid of mercenaries, engaged in hostilities chiefly for the purpose of collecting plunder, or of extorting tribute. Every marauding expedition was approved, provided the leaders brought home a sufficiency of treasure to provide amusements for the people, and to bribe the orators to silence. The official men, in short, inadequately rewarded by their regular salaries, learned, as is almost uniformly the case, to recompense themselves; and the people, either become necessitous by their idle attendance on political matters, or injudiciously supported by the public funds as an encouragement to population, actually depended for their subsistence upon the sacrifices, feasts, and spoils, connected with their military expeditions. While Athens was in this situation, strangely feeble in the whole constitution of its government and population, yet by means of its naval force still the principal republic in Greece, a rival to its power arose in a quarter, which had hitherto attracted little attention, and had even been regarded by the Grecian states as undeserving of their notice. Though the kings of Macedonia pretended to be the descendants of Hercules, the Greeks considered them as no part of their nation, but always treated them as barbarians. This kingdom had existed more than four hundred years, but had generally stood in need of protection from Athens or from Sparta; and had never risen to a capacity of partaking in the eminence of these republics. But it now furnished an example, similar to that of Thebes, of the power of one distinguished individual to accomplish, in favourable circumstances, the most important revolutions. It was in Thebes, indeed, that the new leader of the Macedonians had received his best instructions in the arts of policy and war. Philip had been taken to that city as a hostage when he was only ten years of age, and had been carefully educated under the eye of Epaminondas, assisted by the celebrated Pythagorean philosopher Lysis. At twenty-four years of age he ascended the throne of Macedon, and gave early indication of his talents for government. At the period of his accession, he found himself at war with the Athenians, who supported one of his competitors for the kingdom. Having defeated his adversary, who was slain in the action, he instantly liberated, and loaded with favours, all the soldiers of Athens whom he had taken prisoners.

Having discovered, that the Athenians were intent upon the recovery of Amphipolis, which they claimed as one of their colonies, but which he had seized as the key of his dominions on that frontier, he was equally reluctant to put it in their power, or to come to a rupture for which he was not prepared. With his usual consummate policy, therefore, he declared it in the mean time a free city, and left the inhabitants to maintain their own independence. A peace and alliance were ratified between the Macedonian prince and the city of Athens; but their agreement was of short duration. A contest speedily commenced, which led to the subversion of Grecian freedom by the arts and arms of Philip; but which owed its origin as much to the unprincipled aggressions of the Athenian democracy, as to the ambitious views of the Macedonian monarch. While in full alliance and co-operation with Philip against the Olynthians, they suddenly indicated their hostility to his interests, by detaching the town of Pydna from his kingdom, and making a direct attempt to possess themselves of Amphipolis. Failing in their design, it was soon after occupied by Philip, and rendered a strong barrier between his dominions and those of the Grecian states. Before this time had commenced "the Sacred War," undertaken by the Bœotians, Locrians, Thessalians, &c. in order to punish the Phocians, who had ploughed a field sacred to Apollo at Delphos, and had refused to discharge the fine which the council of the Amphictyons had sentenced them to pay, as an atonement for the sacrilegious deed. They were supported by the Lacedemonians, Athenians, &c. and Philip, well pleased to leave the Grecian states to exhaust their strength against each other, had employed himself in the meantime in extending his power in Thrace, and in attaching Thessaly to his interests, by delivering its cities from the oppressive sway of the tyrants of Pheræ. Irritated, however, by the defection of Olynthus from the Macedonian to the Athenian alliance, he laid siege to that city; and, having gained possession of the place by bribing a party of its inhabitants, he razed its walls to the ground, and sold the people for slaves. The Sacred War, which was still carried on by both parties with the most sanguinary retaliations, next afforded him a fair opportunity of bringing his power into full contact with the Grecian states. Professing to adjust, as arbitrator, the matter in dispute, promising to the Phocians his protection against the fury of their enemies, and soothing the Athenians by the reports of his friends, that he was secretly intending to humble Thebes rather than Phocis, he marched an army into Greece; gained quiet possession of the Phocian cities; secured to that people, as he had promised, their personal safety; but procured, or at least sanctioned, a decree of the Amphictyonic Assembly, annihilating their political existence as a nation, and expelling them from the number of the Grecian states represented in the council. He was himself elected in their place as a member of the Assembly; invested with the double vote which they had enjoyed; and usually denominated in their future operations the Amphictyonic general. The Athenians refused to acknowledge his election; and manifested, in all their measures, an ambition even more unprincipled and indefensible than that of the Macedonian monarch. Guided rather by the inflammatory eloquence of Demosthenes, than by the pacific counsels of Phocion, they plunged at length into a destructive contest with their powerful rival and neighbour. A second sacred war again drew Philip into the midst of Greece. The Locrians of Amphissa having encroached upon the consecrated ground of Delphos, and having refused to obey the decrees of the Amphictyonic council, the Macedonian monarch was invited, as their general, to vindicate their authority by force of arms. Many of the Grecian states were now alarmed, and not without reason, by the forwardness of Philip to interfere in their politics, and by the reluctance which he shewed to withdraw his army, after the punishment of the Amphissians. Demosthenes hastened to Thebes, where he succeeded in rouzing the utmost enthusiasm for the liberties of Greece, and persuaded the Thebans to adopt the immediate resolution of uniting with the Athenians, to resist the dangerous progress of the Macedonian influence. In vain did Phocion recommend, and Philip request, the Athenians to lay aside their measures for instant hostilities. They excluded the former from the command of their army, and marched without delay to join their Theban allies against the enemy. The two armies, consisting of about 30,000 on each side, came to a general engagement at Cheronea. The battle was long doubtful. Alexander, who was only seventeen years of age, at the head of a chosen body of noble Macedonians, cut down the Sacred Band of Thebes; and the Athenians, for a time successful, but urging their advantage with imprudent impetuosity, were overwhelmed by the Macedonian phalanx under Philip. The vanquished were treated with a degree of clemency and generosity, of which there had been few examples in Grecian warfare. Philip hastened to stop the slaughter of the flying Greeks, and dismissed the Athenian prisoners without ransom, and voluntarily renewed his former treaty with that republic. To the Thebans he readily granted peace; but stationed a Macedonian garrison in their citadel. By this decisive victory, he secured the most entire ascendancy in Greece; and, on that side, there was little farther left for his ambition to desire.

Either, however, with a view to extend his conquests, or in order to unite the Greeks more firmly under his power, he planned the invasion of the Persian empire, and procured himself to be appointed generalissimo in the expedition. No measure could have been conceived more popular in Greece. A general council of the states was summoned, and the quota determined which each of them was to furnish. Philip exerted himself with extraordinary activity to complete his formidable preparations; and his whole army, in the most perfect state of military discipline and equipment, was in readiness to cross the Hellespont. But, in the midst of his greatest splendour, while solemnizing, before his departure, the nuptials of his daughter Cleopatra, surrounded by his guards and principal officers, and receiving, among the assembled states of Greece, little less than divine honours, he was stabbed to the heart by a desperate assassin. See DEMOSTHENES, and PHILIP.

Upon the accession of Alexander to the throne of Macedonia, when only twenty years of age, the different nations whom his father had brought under his dominion made an attempt to regain their independence; and Demosthenes exerted all his powers of persuasion to engage the Greeks to unite against the youthful successor of the formidable Philip. But Alexander, having punished the Thracians, Illyrians, and other barbarians, for their indiscretion, turned, with the utmost expedition, the whole weight of his arms upon Greece. The Thebans, who had massacred the Macedonian garrison, which Philip had placed in their citadel, having refused the offer of a free pardon made to them by Alexander, upon condition of their surrendering the principal leaders of the insurrection, were defeated with great slaughter, their city given up to be pillaged, and the inhabitants sold as slaves. These dreadful acts of severity filled the Athenians with alarm, and an embassy was instantly dispatched to implore the clemency of the Macedonian prince. Alexander at first insisted that ten of their principal orators should be delivered into his hands;

but was at length satisfied with the banishment of Charidemus, and expressed the highest regard for the republic of Athens. The other states hastened, in like manner, to make their submission; and, in one campaign, the whole nation of the Greeks acknowledged his supremacy. Having assembled their deputies at Corinth, and renewed the proposal of invading the Persian empire, he was appointed, as his father had been, to the chief command. His rapid conquest of Persia, which would form too extensive an episode in this brief sketch of Grecian history, and which must therefore be passed over without detail, produced one of the most extraordinary and important revolutions in the political aspect of the world. No national contest recorded in history was ever more interesting in its progress, or involved consequences of greater magnitude, than the struggle which had so long been maintained between Persia and Greece. Its object was to decide the great question, whether Europe or Asia should have the ascendancy; and at length, under the auspices of the Macedonian prince, the former gained a superiority, which it has preserved to the present day. During the progress of Alexander's conquests, various attempts were made by the Grecian states to shake off the yoke of Macedonia. The Spartans, especially, under the direction of their king Agis, excited a powerful insurrection in Peloponnesus; but Antipater, who had been left to govern in Macedonia, marching a powerful army into the peninsula, completely broke their spirit by a decisive defeat of their forces, and the death of Agis, who fell in the pursuit. Harpalus, one of the officers of Alexander, who had incurred the displeasure of that prince by his extortions, when governor of Babylon, took refuge in Athens; and, by means of his treasures, succeeded in attaching them to his cause; but, upon the report of a powerful army being dispatched by Alexander to punish their treachery, they expelled Harpalus from their city, and banished Demosthenes, who had been convicted of accepting his bribes. A new commotion also had been excited throughout all the states of Greece, by a proclamation of Alexander to restore the exiles to their respective countries and possessions; and, upon the event of his death being known, the revolt which had already commenced instantly became general. Demosthenes was recalled, and a powerful army of confederated Greeks, under the Athenian commander Leosthenes, marched against Antipater. Elated by the success which attended their first operations, they despised, as usual, the prudent warnings of Phocion, and began to calculate upon the return of their ancient greatness. But Antipater having been joined by Craterus with a part of the victorious army of Alexander, speedily reduced the insurgent states in succession; and, advancing towards Attica, as the great object of his vengeance, though in some measure softened by the intercession of the virtuous Phocion, he abolished the democracy of the Athenians, and established the aristocratical government, as it had existed in the days of Solon; obliged them to pay the expences of the war; and placed a Macedonian garrison in the port of Munychia. Similar changes were made in most of the other states; and, though the people loudly complained, in the first instance, of these infringements upon their liberties, they began at length to feel, that their freedom was in reality greater than it had hitherto been, and acknowledged their obligations to Antipater, by entitling him the Father and Protector of Greece. After the death of Antipater, the Grecian states largely shared in the revolutions and dissensions which agitated, for so many years, the empire of Alexander. Polysperchon, who had been associated with Cassander, the son of Antipater, in the regency of Macedonia, being engaged in a contest with his ambitious colleague, sought to attach the Greeks to his interests, by displacing the governors whom Antipater had placed over them, and by restoring the power of democracy. Several of the cities, particularly Megolopolis, resisted his decree, and drew upon their heads a bloody revenge. Athens, on the contrary, gladly hailed its recovered liberty; and proceeded, in its moments of renewed turbulence, to put to death the friends of Antipater. Among these perished the greatest ornament of their city, the incorruptible Phocion, who had served in the armies and councils of his country till he was above eighty years of age; and whose distinguished merit his fellow citizens soon after acknowledged, with their accustomed inconsistency, by erecting a statue to his memory, and inflicting punishment upon his accusers. But Cassander, by the aid of Antigonus, having recovered his influence in Greece, restored the aristocracy, replaced the Macedonian garrison, and appointed Demetrius Phalerius governor of the city, who conducted himself in his office with so much wisdom and moderation for ten years, that more than three hundred statues are said to have been erected in testimony of his benefits. The power of Cassander prevailed also in Peloponnesus; and, excepting a very few cities, Greece was again entirely subjected to the Macedonian dominion. See ALEXANDER.

During the revolutions which agitated Macedonia, after the death of Cassander, it was invaded and overrun by an immense body of Gauls, who pursued their course like a torrent, and poured upon the enfeebled states of Greece with the utmost fury. They were successfully resisted in the defiles of Thermopylæ, by the Grecian army under Calippus the Athenian; but, forcing their way by the path over mount Oeta, by which the Persians had penetrated under Xerxes, they directed their march to Delphos, with the design of plundering the temple of its accumulated treasures. But, meeting with a brave resistance from those who were assembled to protect the sacred spot, and, being thrown into confusion by a violent storm and earthquake, they fled in the utmost terror, and turned their arms upon one another, in the darkness of the night. They were keenly assailed by the Greeks in their flight, and the greater part of them cut to pieces. Scarcely recovering from the inroad of those barbarians, the states of Peloponnesus were involved in new calamities, by the ambitious arms of Pyrrhus king of Epire, who had reduced the greater part of Macedonia, and having been invited by Cleonymus, an exiled Spartan prince, to redress his grievances, led a powerful army to the gates of Sparta, while their king and the best of their troops were absent in Crete. But the inhabitants of the city, even the women, assisting in its defence, made so heroic a resistance, that time was allowed for the arrival of reinforcements; and Pyrrhus, being compelled to retreat, was slain in an attempt to enter the city of Argos. Antigonus, the son of Demetrius Poliorcetes, being again replaced on the throne of Macedonia, began to meditate the complete subjugation of Greece, and commenced his operations with the siege of Athens, which he speedily reduced, and garrisoned with Macedonian troops. Pursuing his schemes of conquest, he gained possession of Corinth by artifice, but was arrested in his ambitious career by the hand of death. His son Demetrius maintained a commanding influence in the different states of Greece, not by attempting to hold the sovereignty himself, but by supporting those who found means to usurp the supreme authority. His successor, Antigonus Doson, a prince distinguished by his justice and moderation, avoided all interference in the affairs of foreign states;

and the cities of Greece, imitating the example of the Achæan league, made one last attempt to recover their long lost independence.

During the distracted times of Macedonia, under Lysimachus and Ptolemy Ceraunus, the cities of Achaia gradually recovered their liberties, and renewed their ancient confederacy: (See ACHÆANS.) Aratus of Sicyon, having freed his native city from the government of Nicocles, joined the Achæan league, and was chosen prætor of the associated states. Intent upon delivering Peloponnesus from foreign dominion, and hoping to render the Achæan confederation a barrier against future invasion, he surprised the Macedonian garrison in Corinth, and attached the liberated city to the Achæans. He peruaded the governor of Megalopolis to abdicate his power, and follow the example of the Corinthians. Protected by the king of Egypt against the Macedonians, the Achæan confederacy was thus extended on all sides, and might soon have united all the peninsula as one nation, under one government, when its progress was interrupted by the hostility of Sparta. The ancient institutions of that distinguished city had fallen into total disuse, and the manners of its inhabitants had become entirely changed. Many of its kings had incurred deposition, exile, and death, by their attempts to resist the torrent of corruption; and Agis particularly, a young and virtuous prince, had fallen a sacrifice to his well-intended, but ill-executed scheme for restoring the laws of Lycurgus. Cleomenes, one of his successors, revived the prosecution of the plan, but pushed its accomplishment with the spirit of a tyrant, rather than of a reformer. Having massacred the Ephori, and banished the citizens who were unfriendly to his views, and rendered himself despotic at home; he turned his arms against the Achæans, either for the purpose of gratifying his ambition, by acquiring the direction of the confederacy, or, perhaps, only with a view of securing his usurped authority in Sparta, by having an army at his disposal. So strong was the antipathy of the Achæan republics to the prospect of Spartan domination, and so great at the same time their dread of its powerful tyrant, that Aratus was urged to the ruinous resource of calling in the aid of Antigonus Doson, king of Macedonia.* Cleomenes, defeated by Antigonus in the famous battle of Selasia, abandoned his ambitious projects, advised his subjects to submit to the conqueror, and sought a refuge for himself in Egypt. The Spartans were treated by Antigonus with the greatest moderation; but, from that period of its subjection to a foreign power, it sunk into insignificance, and the race of the Heraclidæ became extinct with the successor of Cleomenes. The Achæan league was still preserved entire and powerful, by the able conduct and prudent measures of Aratus; but having sought assistance from Philip of Macedonia, the son of Antigonus, against the Etolians, the inveterate enemies of Achaia, that ambitious ally, conceiving a design to subjugate the cities of Greece, and regarding the integrity of Aratus as an insurmountable obstacle in his way, caused the virtuous patriot to be secretly taken off by poison. The Romans, however, having formed an alliance with the Etolians, in order to occupy the arms of Philip, who had become the active ally of their formidable opponent Hannibal of Carthage, thus acquired a footing in Greece, which gradually led to its final subjugation, as a part of their empire. Philopœmen, the successor of Aratus, supported the cause of Philip as the professed protector of the liberties of Greece, and inspired the confederated states with an ardent love of independence, which long withstood the encroachments of the policy and power of Rome. The struggle maintained in Greece between the Macedonian and Roman interests, was languid and indecisive, while the latter were intent upon reducing the power of Carthage. But, after the conclusion of the second Punic war, more active measures were pursued against Philip. Titus Quintus Flaminius, the consul, partly by the vigour of his arms, but still more by his political dexterity, detached the Etolians, Achæans, and the most considerable of the other states, from all connection with Macedon; compelled the discomfited Philip to accept the most humiliating terms of peace; made a pompous proclamation, at the public games, of the freedom of Greece; withdrew, according to his promise, every Roman garrison from the different states; and left them in full possession of all that political independence which was compatible with the alliance of Rome. Antiochus, king of Syria, instigated by Hannibal, and aided by the Etolians attempting an invasion of Greece, recalled to that devoted country the armies of Rome, and afforded them an opportunity which they did not fail to embrace, of subjecting all that part of Europe to their growing dominion. After reducing and dismembering the kingdom of Macedonia, they were invited to assist the Spartans in a contest with the Achæan states: they soon succeeded in breaking the power of the confederacy, by seducing a part of the cities of which it was composed; and Philopœmen, generally designated the last of the Greeks, having fallen in an expedition against the revolted Messenians, it became no difficult task to accomplish the total overthrow of the confederacy, of which he had been so long the principal ornament and support. Above a thousand of the Achæan chiefs, accused of having acted in concert with Macedonia, were transported to Rome, to answer for their conduct at the tribunal of the senate. The Achæan constitution was, soon after, entirely dissolved; the whole of Greece reduced to the state of a Roman province, under the name of Achaia; and, from that period, its history comes properly to be included under that of Rome. See ACHÆANS, MACEDONIA, and ROME.

But Greece, though subject to the Roman arms, soon acquired, by her arts of peace, a silent superiority over her conquerors. The victors became the disciples of the vanquished; and the most distinguished Romans learned, in the Grecian schools of philosophy, to regard the country which they held in subjection, with the gratitude and respect due to a benefactor. These considerations probably contributed to secure to the inhabitants of Greece a milder exercise of authority, and more distinguished marks of favour, than were enjoyed by any other province under the yoke of Rome. Of these arts and attainments, to which this singular people were thus indebted for higher honours and advantages than all their military prowess had been able to command, we now proceed to offer an abridged view, as a suitable conclusion to the preceding sketch of their eventful history.

Of the state of society and knowledge among the earlier Greeks, particularly in what has been called the heroic age, as described in the writings of Homer, some account has already been given, when narrating the events of that period; and the remarks which follow apply chiefly to those times which were posterior to the first Persian war.

* The cities of Greece being so much decayed in strength, and unable to assume the attitude of independence, Aratus may be regarded as having adopted, if not the wisest, at least the only measure of security in his power. His object was to render the kings of Macedonia, the allies and protectors, in place of the masters and tyrants of the united commonwealths; and, by yielding so far to an influence which could not be withstood, to procure a free regulation of their internal concerns, and particularly an exemption from the odious and oppressive presence of foreign garrisons.

To agriculture, as an object of study, the Greeks paid little attention; and the care of its operations was almost entirely left to slaves. The Athenians considered themselves as having first received the common principles of the art from Egypt, and as having communicated the knowledge of it to the other countries of Greece. Attica itself, however, was adapted rather to the cultivation of fruits than of grain. Olives and barley formed its principal produce, and the citizens of Athens received their great supplies of wheat from the neighbouring states of Bœotia, or from their own colony of Byzantium. Their writers on the subject, among whom was Xenophon, have done little more than merely detail the common practices of their own times.

The inhabitants of Greece, though possessing a maritime country, surrounded with islands, and provided with excellent harbours, were extremely slow in availing themselves of these advantages; and made little progress in navigation and commerce, till after the expedition of Xerxes into Peloponnesus. After the example of Athens, especially in the course of the Peloponnesian war, the other states at length directed their attention to the maintenance of a navy; but chiefly for the purposes of warfare. The voyage of Alexander's fleet from Patala to Susa, after sailing down the Indus, was the first instance of Greeks navigating the ocean; and, previous to that expedition, they were entirely confined to the waters of the Mediterranean.

Excepting Corinth and Athens, it was principally in the smaller states, such as Megara, Sicyon, Cos, and Cnidus, (which possessed not sufficient political influence to interfere in the general affairs of Greece,) that the arts of commerce were most sedulously prosecuted. Athens, however, was the great seat of commercial views, where every circumstance favoured the acquisition, and encouraged the expenditure of wealth. Its port, Piræus, was then the centre of the traffic of those times, and there every commodity was to be found in abundance.

The fine arts appear to have attracted earlier attention in Greece, than the more useful occupations; and some of the ancient medals, long prior in date to the oldest historians, exhibit a chasteness and grandeur of design, both in architecture and sculpture, for which it is difficult to account.

The customs and circumstances of the Grecian states tended directly to encourage the progress of these arts. Three public buildings were indispensible in every city; a temple, a theatre, and a gymnasium, to which were afterwards added the baths, and portico or place of shelter for walking and conversing. In larger towns these edifices were soon multiplied, especially those for the service of religion; and every city almost forming a distinct community or nation, each required to possess these different buildings within its own walls, and strove to surpass its neighbours in the solidity and beauty of its public structures. The exertions of the Greek artists in this at once useful and ornamental study, are not therefore very wonderful; but, when it is considered, that its first architects derived their skill from those of Egypt and Persia, and that the Doric order, the foundation of all the rest, and the source of pure taste to all the architecture of Greece, was actually the most ancient, it is not easy to conceive by what accidental or intended principle of the art, a beautiful simplicity, so opposite to the enormous masses of the Egyptians, and cumbrous ornaments of the Asiatics, should have been so happily introduced; unless we ascribe it to the mere circumstance of necessity (the origin of so many human improvements) which obliged the early architects of that country to work with wooden materials: (See Civil Architecture.) But in whatever way we may account for the rise of Grecian architecture, its principles have received the approbation of every enlightened people in modern times; and its three orders, the Doric, Ionic, and Corinthian, still continue to form the invariable standard of good taste in the art.*

The same causes which rendered the skill of the architect so much in request, equally tended to encourage the labours of the painter and sculptor; and it is a remarkable circumstance, that, in the most turbulent periods of Grecian history, the fine arts received the most distinguished patronage, and made the most rapid progress. At Athens, particularly, the genius of Greece was nourished by Pisistratus, and brought to perfection by Pericles. The most eminent sculptors of those times were Phidias, Alcamenes, and Myron, of Athens; Polycletes and Lysippus, of Sicyon; Praxiteles and Scopas of Paros; and many of the ancient statues which have escaped the ravages of time, furnish ample testimony of the progress which had been made in the art. See Drawing and Sculpture.

Of the state of painting among the Greeks, many exaggerated and incredible accounts have been given by ancient authors. They used only four colours, black, white, red, and yellow; and knew nothing of painting in oil. They are considered also as having been very imperfectly acquainted with the effects of light and shade; and many pieces of ancient Mosaic, still preserved, are not much admired as performances in painting. Both in painting and statuary, the Greek artists produced representations of the human form, which could scarcely be called natural. By taking collective views of the species, and studying accurately the physical constitution of the body of man, they combined its various and scattered excellencies in one figure, and thus exhibited, what nature never does, a model of abstract and ideal perfection. Among the celebrated painters may be mentioned Polygnotus, who received the thanks of the Amphictyonic assembly for his painting of the Trojan war, placed in one of the porticos of Athens; Apollodorus, who is supposed to have invented the art of painting in clear-obscure; Zeuxis, who displayed himself at the Olympic games, dressed in purple and gold, and, having become wealthy, gave his works as presents, because he said they were above all price; Parrhasius, who insolently presented himself to public view with a crown of gold upon his head; Pamphilus, the first who applied the principles of science to his art; Timanthes, who produced the celebrated painting of the sacrifice of Iphigenia; Apelles, who exposed his works to public view, that he might derive improvement from the remarks of passengers; and Protogenes, the rival of Apelles, who censured the extreme minuteness of his contemporary, by saying, that "he knew not when to lay down his pencil."

Few things are more remarkable in the manners of the ancient Greeks, than the great importance which they attached to the musical art, which, in many of the states, was even regulated and recommended by the laws. It was considered as one of the most powerful means of influencing the sentiments of the people, and formed an essential part in the education of the youth. The ancient musicians are supposed to have been wholly ignorant of the art of performing pieces of music in different parts at the same time; and their compositions, especially the pathetic and warlike, are generally understood to have derived much of their effect from the poetry and sentiments with which they were combined.

* See an examination into the grounds of this preference in the Rev. Mr Alison's *Essay on Taste,* vol. ii. p. 156.

The honours and rewards lavished upon those who excelled in the fine arts, were doubtless one principal cause of the improvement which they reached; but often were they carried to a hurtful excess, exhausting the wealth which was wanted for the support of the state, and engrossing the rewards which were due to more essential services.

But the great occupation of the Greeks as a people, were war and politics. Leaving the ordinary labours of agriculture and the mechanical trades to the slaves, the citizens of the different states considered it as their peculiar privilege to share in the government of their country, and to fight in defence of its rights, or for the advancement of its power. Every citizen, therefore, being bound to serve in arms, was enrolled as a soldier at a certain age; and one of their regular employments was the exercise of the gymnasium, as a preparative for the toils of war. The armies were composed principally of heavy-armed infantry, attended by a number of slaves to carry the baggage, and serve in the camps, and sometimes to act as light armed troops. The arms of the infantry were a helmet, corselet, large brazen shield, leathern greaves or boots, long pike, and short sword. They were long accustomed to advance, in a compact body, to close fight; but Iphicrates, an Athenian general, introduced the employment of a greater proportion of light infantry, diminishing the weight and size of the buckler, exchanging the metal corselet for one of canvas, lengthening considerably the lance and sword, and accustoming the troops thus accoutred to the most active evolutions. That celebrated commander, describing an army as a human body, compared the general to the head, the heavy-armed infantry to the breast, the cavalry to the feet, and the light troops to the hands. Chariots were little used after the heroic age; and, for want of horses, cavalry were never numerous, generally consisting of the wealthier citizens, or of soldiers fitted out at their expence. Till the time of Philip of Macedon, the Greeks were little acquainted with the art of conducting sieges, but commonly limited their operations to a general assault, or inactive blockade. In long or distant wars, especially in the later ages of Greece, the citizens received pay, while serving in the field; but the constant object of every Grecian state was to support their troops at the expence of the enemy. Even in the most civilized periods, Grecian warfare was conducted with a spirit of rapine and barbarity, which seemed to increase, instead of diminishing, as knowledge and refinement spread among the people. Retaliation was considered as justifying the most atrocious measures, of which, in the course of the Peloponnesian war particularly, many instances occurred, in the proceedings of all parties. The Lacedemonians regularly massacred the crews of the Athenian merchant vessels, and even of neutrals, whenever they came in their way; and the Athenians deliberately decreed the extermination of the Æginetans and Scyonians, whom they put to death without distinction.

The Greeks distinguished six simple forms of government, namely, monarchy, hereditary or legally established, oligarchy, aristocracy, democracy, tyranny, and assumed oligarchy, of which the two last were considered as illegal and inadmissible. The title of King never implied among them the possession of absolute power, but only a legal and regulated superiority, particularly in directing the observances of religion, and the operations of war, and sometimes also in dispensing justice, but rarely in enacting laws. After the general abolition of monarchy in Greece, whenever a citizen of a commonwealth was raised by any means to monarchical authority, he was denominated Tyrant, not originally as a term of reproach, though in future times it came too justly to be applied in that sense. In Athens especially, as early as the days of Theseus, the nobly born formed a distinct class of the community, and were invested with great privileges; but hereditary nobility declined every where along with monarchy, and wealth became the principal cause of distinction among the citizens. Those who were able to serve in war on horseback at their own expence began to be regarded as a superior rank; and to the same circumstance may be traced the order of knighthood in most countries. Aristocracy, however, was less a regularly instituted form of government, than an assumed title adopted by the rich and the noble in those states where they held the chief power; but, as their administration was generally oppressive, oligarchy, or the government of a few, became a more frequent, though less honourable form of polity; and the term aristocracy was at length employed rather to signify those persons who, on account of distinguished merit, were elected by the people to undertake the management of public affairs. This last was commonly the mode adopted in the most democratical states; and pure democracy, in which all the freemen of the republic, in assembly, formed the supreme and absolute administration, was very rarely exemplified, and was usually denominated ochlogracy or mob-rule. Most of the Grecian governments contained a union of two or more of these forms; and, from these various mixtures, new distinctions and designations arose, which it would be tedious and unprofitable to trace. Of political economy the Greeks seem to have been extremely ignorant; and very little is known respecting their mode of managing the public finances. On the subject of population, it does not very clearly appear what was their regular system. They certainly employed many regulations for keeping up at least, if not for increasing, the number of their citizens; yet they shewed a decided aversion to any augmentation of their strength by the admission of foreigners to the privileges, or even to the protection of their state. They studied to preserve their townships completely insulated and distinct from all others; and prohibited intermarraige with the members of a different community, with all the jealousy of feudal clanship.

Amidst all the turbulence of the Grecian states, and the almost perpetual hostilities in which they were engaged, there were many circumstances favourable to the cultivation of literature and science. Few individuals possessed large properties, but many of them lived in great leisure, following no occupation themselves, and principally maintained by the labour of slaves. Assembled generally in towns, and having free intercourse with one another, polite manners were formed, and various opportunities were presented for the display of taste and genius. A lively imagination, and love of novelty, were general characteristics of the Greeks, and disposed them to welcome every ray of knowledge which beamed upon their limited society. Many, possessed of active and intelligent minds, yet less daring in their dispositions, or more scrupulous in their integrity, shunning the stormy paths of political ambition, sought employment and distinction by attainments in literature or science. Even those who aimed at the offices of statesmen, found a degree of general knowledge, especially in the pursuits of taste, and the arts of eloquence, highly advantageous to enable them to command attention in the public assemblies, and to assist them in swaying the minds of their fellow citizens. As knowledge increased among the members of a community, these qualifications became not merely useful, but essential to every political leader; and many, who were unable, or unwilling, to mingle in the struggle for public situations, found a less splendid, but often more gainful occupation, in communicating to others those literary acquisitions which had become so subservient to the success of public men. At length every city in Greece, but especially Athens, abounded with those persons, who, under the name of Sophists, undertook to teach every branch of science; and, at a time when books were few and expensive, the oral communication of knowledge was obviously a matter of the utmost importance.* These professors of wisdom studied the accomplishments of eloquence, to render their instructions more attractive; and frequenting all the places of public resort, strove to recommend themselves to notice by an ostentatious display of their abilities, especially by public disputations with one another, or with any who chose to converse with them amidst a circle of hearers. Grecian philosophy is generally admitted to have originated with Thales of Miletus, the contemporary of Solon, and the founder of the Ionian school. Soon after him arose Pythagoras, a native of Samos, who was compelled, by political troubles, to take refuge in Italy, and thus became the leader of what has been called the Italian school. Both these sages are understood to have acquired their learning in Egypt and Persia; but so much was it the practice of the Greeks to claim as their own, what they had merely purloined from the literary treasures of other nations, that it is impossible to ascertain what portion of their science was indigenous, and what of foreign growth. Both Thales and Pythagoras inculcated many valuable moral precepts, but they were not teachers of ethics as a system; and their countrymen of the Asiatic Greeks were more delighted with those metaphysical enquiries, respecting the nature of matter and spirit, the formation of the world, and laws of the heavenly bodies, which gratified their imagination, without proposing any restraint to their passions. It was during the administration of Periander at Corinth, and Pisistratus in Athens, that the love of these sciences was first kindled in Greece; but the growth of every liberal art was entirely checked by the violent political contests and revolutions which ensued, and particularly by the general alarm of the Persian invasion, which left no leisure for speculative pursuits. But when the commanding talents of Pericles had quieted the tumults of faction in Attica, the pursuits of science revived at Athens with new vigour; and, together with the fine arts, continued to receive improvement during all the turbulence which attended the progress and effects of the Peloponnesian war. During this period it was, that Anaxagoras of Clazomene introduced the best principles of the Ionian school, that Socrates dispensed his more practical instructions, that Plato wrote and taught his more refined speculations, that Lysias and Isocrates pleaded in the forum, and that Aristotle and Demosthenes studied in the schools of Athens. Anaxagoras first taught in Athens the existence of one eternal and supreme Being, or, as he is said to have expressed himself, "a perfect mind, independent of body," as the cause or creator of all things; and, by enabling his pupils to calculate eclipses of the sun and moon, proved these hitherto reputed divinities to be mere material substances. But his doctrine was so directly repugnant to the whole religious notions of the Grecian people, that he was accused of impiety, and obliged to withdraw from the Athenian territories. Socrates, early impressed by the sublime principles of theology taught by the exiled philosopher, yet, perceiving the inutility, or at least the unpopularity of such discussions respecting the nature of the Deity, applied himself rather to investigate the duty which man ought to render to such a Being, as Anaxagoras had described the great Creator. He seems to have settled it as a first principle, that, if the providence of God interfered in the government of the world, the duty of man to man must form a distinguished branch of the divine will. He therefore applied himself to examine and inculcate the social duties; and, possessing a most discriminating and ready eloquence, he rendered his conversation (the only mode of teaching which he employed) at once amusing and instructive. He was always to be found wherever there was the greatest resort of company, and was ready either to receive or to communicate information; but he would neither undertake the office of private instruction, nor accept a reward for his public labours. While he maintained the perfect wisdom and perfect goodness of the Supreme Being, and the constant superintendance of his providence over the affairs of men, he continued to observe and to recommend the various acts of religious worship which were practised in his native country. But all his caution and worth were unable to secure his protection against the jealous tyranny of Athenian democracy; and, either from an impression that he disapproved of their popular constitution, or from a dislike of his purer system of morals, he was rendered so obnoxious to his fellow citizens, that a decree was easily procured for his death. After the time of Socrates, the Greek philosophers were divided into two opposite sects, the Theists and Atheists. The latter, among whom were Leucippus, Democritus, Epicurus, &c. supported the opinion of Anaximander, that, without the aid of a supreme intelligence, all things were produced by a necessary action of matter, assuming all kinds of forms; and the former, among whom were Plato, Aristotle, Zeno, &c. adhered to the doctrine of Anaxagoras, respecting the existence of a Deity, while they held different notions as to his nature and attributes. Even those, however, who possessed the more correct ideas of the Supreme Being, almost without exception conceived the world to be governed by a number of inferior divinities, to whom different departments of the universe had been committed; and, as they readily conformed to the existing religious usages of their respective countries, their philosophical system and private example rather countenanced than counteracted the popular polytheism of antiquity. The origin and progress of the Grecian mythology, it is now impossible to trace with any probable degree of certainty. Whether it arose from the Chaldean hypothesis of the planets and elements being inferior divinities, and established mediators

* If an attempt were made to estimate the literary and scientific attainments of the ancient Greeks, the following would probably be found to be a few of the principal results; namely, that, in *literature*, it was rather in the entertaining than in the instructive branches that they made any extraordinary progress; and, even in history, produced merely exquisite narratives of events, without any exposition of their causes or relations;—that, in *moral science*, they excelled in acute disputations upon practical questions, and elegant manuals of useful precepts, but never ascended to any enquiry deserving the name of philosophy;—that, in *political science*, they described the most striking phenomena of government in the different states of their own country, or of the neighbouring nations, but made no researches into the principles, the ends, the safeguards of national constitutions;—that, in *physical science*, their progress was astonishing in the single branch of geometry, while they never thought of investigating the properties of physical bodies, or the order of physical events;—that, in *philosophy of mind*, the logic of Aristotle contains an ingenious but unsuccessful analysis of the process of general reasoning, while his metaphysics explains only the various uses which were made of general terms, and vainly attempts to penetrate the essences and causes of things, but nothing is done to arrange the phenomena of thought, or to ascertain the order of their succession; that "not one, in short, of the ancient philosophers had any conception of the real nature of general terms, or of the operation of mind which is called abstraction; and that it was chiefly by this radical defect, that they were perpetually perplexed, and led into all their trifling and absurdity."

between man and the one supreme God; or from the allegorical mode employed by the Egyptians of describing the attributes of the Deity; or from a poetical personification of the operations of nature; or from a fabulous embellishment of real events, in the first periods of Grecian history; or from mutilated traditions of the lives of the Hebrew patriarchs; or rather, which seems the most likely, from a mixture of all these, and perhaps other unknown sources;—one thing seems evident, that if it ever possessed the symmetry of a philosophical system, its unity was destroyed before it was described by any writer of antiquity whose works are now extant.

The theogony of Hesiod may be considered as the earliest and most entire account of the religious tenets of the Greeks; but it is affirmed by Herodotus, that, along with the divinities of the first inhabitants of Greece, the poet has mingled the gods of Libya and Egypt. The system, in short, admitted in some degree by the philosophers, assumed and altered by legislators, as best suited their purposes, embellished and expanded by the poets, as their imaginations pleased, became at length an inextricable mass of mysterious absurdities and ideal beings, of which we cannot attempt to furnish any consistent account. Neither can we afford space for enumerating the leading sects, and distinguishing tenets, and scientific attainments, of the different philosophers of Greece; but the most important and authentic information on these topics will be found under the articles devoted to their respective names. (See particularly Academics, Atomical Philosophy, Peripatetics, Stoics, Anaxagoras, Aristotle, Epicurus, Plato, Pythagoras, Socrates, Zeno.) It may be observed, in general, that the great defect of their physical science was, the want of experiment; and thus, having no fixed principles upon which to proceed, they had recourse to mere hypothesis and conjecture, amusing themselves with framing fanciful systems, while they should have been employed in actual observations. Hence a taste for sophistry and subtilty prevailed in every school of Grecian philosophy; and it became the boast of their teachers of wisdom to be able to support either side of a question, and to give plausibility to the most parodoxical opinions. This pernicious practice was soon transferred from the more abstruse speculations, to the more practical, political, and moral obligations. Its prevalence naturally gave rise to the sect of the Pyrrhonists or Sceptics, whose distinguishing principle was universal doubt, which they carried to such a degree of extravagance, as to pronounce every external object a mere illusion, and the life of man a perpetual dream. Neither the speculations of the philosophers, nor the fictions of the poets, were much calculated to favour the obligations of moral duty; and, even where their tendency was most unexceptionable, their influence was feeble.

At no period of Grecian history does their appear any thing deserving the name of evidence to prove the exitsence of that virtuous age, which more modern declaimers have delighted to describe rather in the spirit of poetical romance, than of historic accuracy. In the earlier ages, violence and rapine, except in as far as they were occasionally restrained by the solemn obligation of oaths, form the prevailing feature of the people and their leaders. In the more enlightened periods, in the times even of Plato and his disciples, the clearest principles, we do not say of moral purity, but even of moral integrity, were not better understood, and still less better observed, than in the days of Homer. Philosophy relaxed the hold of superstition upon the conscience, without substituting any efficacious restraint in its place; and "it is evident," to use the words of Mitford, "from the writings of Xenophon and Plato, that, in their age, the boundaries of right and wrong, justice and injustice, honesty and dishonesty, were little determined by any generally received principle." The philosophy of Epicurus had completely gained the ascendency in the age preceding the Christian era; and the greatest characters, and most learned scholars, wavered between the tenets of the theistical and atheistical systems. Corruption of manners, and the subtilties of scepticism, had reached a height of extravagance, which it seemed scarcely possible to exceed. Human reason had lost itself in the labyrinths of philosophical speculation; and human virtue had been abandoned to the wayward direction of the fancy or the passions. The history of the world had demonstrated (and it is the best lesson, which a review of its most interesting portions can teach) the necessity of some surer and more authoritative guide to man, than what the wisdom of the world had been able to afford him, either as a member of society, or a being formed for immortality. See *Ancient Universal History*; Millot's *Elements of General History*, vol. i.; Goldsmith's *History of Greece*; Rutherford's *View of Ancient History*; Gillies's *History of Greece*; Gillies's *History of the World*; Potter's *Antiquities of Greece*; Anacharsis's *Travels in Greece*; Leland's *History of Philip of Macedon*; Pausanias' *Description of Greece*; *Religion of the Ancient Greeks illustrated, by* M. Le Clerc; Newton's *Chronology*; Bossuet's *Universal History*; and particularly Mitford's *History of Greece*, a historical work, unequalled in modern times for extensive research, judicious conclusions, and well-arranged narrative. GREECE, Modern. See Turkey.

GREEK Music, *Ancient*. It appears from the writings of Aristoxenus, the earliest writer on the music of the Greeks whose works are extant, that before his time, their scale of music had been extended to two octaves, by the raising of a major tone, and then three succeeding minor fourths, upon the lowest of the notes of this double octave, and by the descending of two such succeeding minor fourths, from the upper note of this double octave: each of these fourths, or diatessara, being exactly of the same magnitude, and alike constituted, as to the situations of its two interior notes, throughout each of their several genera, and the colours or species of each.

The *fourth* being thus made the unvarying boundary of every one of the numerous Greek systems, as the *octave* is now with us, and as the major *sixth* was with Guido, in the formation of his scale: In the genus Diatonicum (which see) each fourth was made up of a semitone and two tones; in the genus Chromaticum, of two semitones and a minor third; and in the genus Enharmonicum (see Genera) of two quarter tones or diesis, and a major third; each of which semitones, tones, thirds, and diesis, were varied, or have different values assigned them, by almost every different writer, as references to our articles above mentioned will shew; but so as always to preserve the fourth entire and perfect: and it has been concluded, that every one of these writers intended five of the *fourths* which he has described to be disposed within two octaves, from A to A, as above mentioned; the third of these fourths, tuned from below, overlapping the second of those two tuned from above, by a grave or comma-deficient minor third, as will be best explained by giving an example of the *Diatonicum intensum* of Ptolemy, which can be done, with reference to the notes of Mr Liston's scale, (see Euharmonic *Organ*), using the artificial commas of Farey's *Notation* (which see.) for expressing the magnitudes of the several intervals; viz.

| Notes in Liston's Scale. | | Values of the Notes above A. | | Intervals of the several adjacent Notes. | |
|---|---|---|---|---|---|
| | | Σ | Σ | Σ | Σ |
| | A | | 1224 | | |
| | G | | 1131 | | 93 |
| | F | | 1027 | | 104 |
| | E | | 970 | | 57 |
| | D | | 877 | | 93 |
| D' | | 866 | | | 104 |
| C | C | 773 | 773 | 93 | |
| | B | | 716 | 104 | 57 |
| B♭ | | 669 | | | 104 |
| A | | 612 | 612 | 57 | |
| G | | 519 | | 93 | |
| F | | 415 | | 104 | |
| E | | 358 | | 57 | |
| D | | 265 | | 93 | |
| C | | 161 | | 104 | |
| B | | 104 | | 57 | |
| A | | 0 | | 104 | |

(Brackets in the table: values 612–1224 "Second Octave."; values 0–612 "First Octave."; intervals grouped as "1st 4th. 2d 4th.", "3d 4th.", "4th 4th.", "5th 4th.")

The first of the above three columns contains the notes of Mr Liston's scale, and opposite to each of these, its value in the artificial comma (Σ) is placed. In column three, intermediary to the lines of the first two columns, the difference of the adjacent numbers in column two are placed, by which it will appear that each of the five tetrachords or fourths, BE, EA, AD', and BE and EA, are exactly alike constituted, that is, rise each by the intervals 57, 104, and 93 artificial commas each, answering to the major semi-tone, the major and the minor tones respectively.

The interval AB, is in each case 104, or the major tone; and thus, exclusive of the notes B♭ and D', the system comprised in these two octaves may be more simply expressed thus, viz. T+4th +4th+ T + 4th+ 4th =2 VIII, forming thus far two similar octaves. The interval D'B or 866—716 = 150, is the comma-deficient minor third, by which interval the two series of fourths overcap each other.

It would be easy for the musical student to prepare a similar table to the above columns two and three, for each of the many Greek systems, whose fourths are given in Σ S, in our articles on the *Genera* above referred to, and to place Liston's corresponding notes against them, in column one, as far as is practicable, by reference to the values of his notes in the *Philosophical Magazine*, vol. xxxix. p. 419, whence the above numbers were derived, by adding 161 from C to C, and 773 from C to *a*; that is, by reducing Liston's series to A as a bass or key-note, instead of C. GREENSTONE. See Mineralogy.

GREEN, Matthew. Of this author of a popular poem, *The Spleen*, very few particulars are known. He was nephew to a Mr. Tanner, the clerk of Fish-mongers Hall, and belonged to a reputable family among the Dissenters. But though bred among the sectaries, he grew disgusted with their precision, and probably left them without being reconciled to the mother-church, as he is said to have thought freely on points of religion. He had a post at the custom-house, which he discharged with great fidelity, and died at a lodging in Nag's head Court, Grace-church street, at the age of forty-one, in 1737. Green's character is given by his intimates as that of an exceedingly honest man, witty and original in conversation, though slenderly educated; and agreeable in manners, though subject to the hip. Once when his friend Sylvanus Bevan, a Quaker, was complaining at Batson's coffee-house, that, while bathing in the river, he had been saluted by a water man with the usual cry of *Quaker Quirt*, and wondered how his profession could be known while he was without his clothes; Green replied, "by your swimming against the stream." A reform took place at the custom-house, while he belonged to it, by which, among other articles, a few pence, weekly allowed for milk to the cats, were taken away. On this occasion, Green wrote a petition from the cats, which prevented the regulation from taking place. The poem of the Spleen was never published in his lifetime, nor any of his fugitive pieces. Glover, his warm friend, presented it to the world after his death; and, it is much to be regretted, did not prefix any account of its interesting author. It was originally a very short copy of verses, and was gradually and piece-meal enlarged. Pope speedily noticed its merit; Mr Melmoth praised its strong originality, in Fitzosborne's Letters; and Gray duly commended it in his correspondence with Lord Oxford, when it appeared in Dodsley's Collection.

It would be as superfluous here to enter upon a serious defence of the poem of the Spleen, as it was absurd in the last editor of the British Poets to attack it upon the grounds of its author professing to offer no religious consolations for the cure of splenetic temperaments. Religion would have been quite as much misplaced amidst those light views of life which the author exhibits, as in a sentimental comedy. The views of life which he takes, are not indeed marked either by strong sensibility, or profound observation; but the *light* in which he arrays familiar scenes and situations, is peculiarly original. The matter of his precepts is common, while their manner of expression is happy, and all his own. The concluding allegory, for instance, in which life is compared to a sea voyage, is extremely hackneyed, yet nowhere has the allegory been renovated by so many, and by so fine picturesque circumstances. Reason at the helm; the Passions forming the crew; Philosophy putting forth the lights; Experience employing the glass and lead; the careening places of Bath and Tunbridge; and the dolphins sporting round; all compose a picture of animated and amusing effect. Many of his scattered thoughts and detached sentences, fairly rival the best in Butler; and upon the whole leave it much to be regretted, that so ingenious a mind should have been destined by a short life, and by the bondage of a confined vocation, to leave such scanty relics of its powers. (*n*)

GREENE (Nathaniel,) a major-general of the army of the United States, was born in Warwick, Rhode Island, about the year 1740. His parents were quakers. His father was an anchor-smith, who was concerned in some valuable iron works, and transacted much business. While he was a boy, he learned the Latin language chiefly by his own unassisted industry. Having procured a small library, his mind was much improved, though the perusal of military history occupied a considerable share of his attention. Such was the estimation in which his character was held, that he was at an early period of his life chosen a member of the assembly of Rhode Island. After the battle of Lexington had enkindled at once the spirit of Americans throughout the whole continent, Mr Greene, though educated in the peaceful principles of the friends, could not extinguish the martial ardour which had been excited in his own breast. Receiving the command of three regiments with the title of brigadier general, he led them to Cambridge; in consequence of which the quakers renounced all connexion with him as a member of their religious body. On the arrival of Washington at Cambridge, he was the first who expressed to the commander in chief his satisfaction in his appointment, and he soon gained his entire confidence. He was appointed by congress major general in August, 1776. In the battles of Trenton, on the 26th of December following, and of Princeton, on the 3d of January, 1777, he was much distinguished. He commanded the left wing of the American army at the battle of Germantown, on the 4th of October. In March, 1778, he was appointed quarter-master-general, which office he accepted on condition, that his rank in the army should not be affected, and that he should retain his command in the time of action. This right he exercised on the 28th of June, at the battle of Monmouth. His courage and skill were again displayed on the 29th of August in Rhode Island. He resigned in this year the office of quarter-master-general, and was succeeded by colonel Pickering. After the disasters which attended the American arms in South Carolina, he was appointed to supersede Gates, and he took the command in the southern department December 3, 1780. Having recruited the army, which had been exceedingly reduced by defeat and desertion, he sent out a detachment under the brave general Morgan, who gained the important victory at the Cowpens, January 17, 1781. Greene effected a junction with him on the seventh of February, but on account of the superior numbers of Cornwallis, he retreated with great skill to Virginia. Having received an accession to his forces, he returned to North Carolina, and in the battle of Guilford on the 15th of March was defeated. This victory, however, was dearly bought by the British, for their loss was greater than that of the Americans, and no advantages were derived from it. In a few days Cornwallis began to march towards Wilmington, leaving many of his wounded behind him, which had the appearance of a retreat, and Greene followed him for some time. But, altering his plan, he resolved to recommence offensive operations in South Carolina. He accordingly marched directly to Camden, where, on the 25th of April, he was engaged with lord Rawdon. Victory inclined for some time to the Americans, but the retreat of two companies occasioned the defeat of the whole army. Greene retreated in good order, and took such measures as effectually prevented lord Rawdon from improving his success, and obliged him in the beginning of May to retire beyond the Santee. While he was in the neighbourhood of Santee, Greene hung in one day eight soldiers, who had deserted from his army. For three months afterwards no instance of desertion took place. A number of forts and garrisons in South Carolina now fell into his hands. He commenced the siege of Ninety Six on the 22d of May, but he was obliged on the approach of lord Rawdon in June to raise the siege. The army, which had been highly encouraged by the late success, was now reduced to the melancholy necessity of retreating to the extremity of the state. The American commander was advised to retire to Virginia; but to suggestions of this kind he replied, "I will recover South Carolina, or die in the attempt." Waiting till the British forces were divided, he faced about, and lord Rawdon was pursued in his turn, and was offered battle after he reached his encampment at Orangeburgh, but he declined it. On the eighth of September, Greene covered himself with glory by the victory at the Eutaw springs, in which the British, who fought with the utmost bravery, lost eleven hundred men, and the Americans about half that number. For his good conduct in this action, congress presented him with a British standard and a golden medal. This engagement may be considered as closing the revolutionary war in South Carolina. During the remainder of his command he had to struggle with the greatest difficulties from the want of supplies for his troops. Strong symptoms of mutiny appeared, but his firmness and decision completely quelled it.

After the conclusion of the war he returned to Rhode Island, where the greatest dissenisons prevailed, and his endeavours to restore harmony were attended with success. In October 1785, he sailed to Georgia, where he had a considerable estate not far distant from Savannah. Here he passed his time as a private citizen, occupied by domestic concerns. While walking without an umbrella, the intense rays of the sun overpowered him, and occasioned an inflammation of the brain, of which he died June 19, 1786, in the forty-seventh year of his age. In August following, congress ordered a monument to be erected to his memory at the seat of the federal government.

General Greene possessed a humane and benevolent disposition, and abhorring the cruelties and excesses, of which partizans on both sides were guilty, he uniformly inculcated a spirit of moderation. Yet he was resolutely severe, when the preservation of discipline rendered severity necessary. In the campaign of 1781, he displayed the prudence, the military skill, the unshaken firmness, and the daring courage, which are seldom combined, and which place him in the first rank of American officers. His judgment was correct, and his self-possession never once forsook him. In one of his letters, he says, that he was seven months in the field without taking off his clothes for a single night. It is thought that he was the most endeared to the commander in chief of all his associates in arms. Washington often lamented his death with the keenest sorrow. *Hillhouse's oration on his death; American Museum*, ii. 337—343; iii. 23; vii. 39—41, 107—109, 210, 211; *Massa. Magazine*, iv. 616, 671; *Gordon*, ii. 65; iii. 473; iv. 168, 406; *Marshall*, iii. 219; iv. 263, 335, 540, 556; v. 116; *Ramsay's South Carolina*, ii. 190—193, 204—225, 245—251; *Hardie; Holmes' Annals*, ii. 440—449; *Stedman*, ii. 376; *Warren*, iii. 56—59.

# GREENLAND.*

Greenland is the most northern country of the western hemisphere of the globe. It reaches as far as the land is discovered, from Cape Farewell, in Latitude 59° 30′ to the 78th degree of North Latitude. Its eastern coast runs north-east towards Spitzbergen, and is bounded by the Atlantic Ocean. Its western coast has a northwest direction, and is bounded by Davis Straits and Baffin's Bay. Its southern coast is very narrow, not occupying one degree. The borders of its northern coast are entirely unknown. The eastern coast is commonly called East Greenland, and Osterbygd by the old Icelanders, and Norwegians; the western, West Greenland, and Westerbygd; *bygd* signifying, in the old Icelandic language, settlement. From the date of its recovery, the former is called Old Greenland, the latter New Greenland. The whale fishers, speaking of Greenland, include under this name the islands

* The Editor has been indebted for the following article on Greenland to the Chevalier Charles Louis Giesecke, Professor of Mineralogy to the Dublin Society, who resided many years in that country, for the express purpose of examining its mineralogy and natural history.

of Spitzbergen, so called from the many sharp-pointed mountains with which it abounds, and they call the whole west side Davis Strait. The Danes further divide the west coast into South Greenland, a distance from 59° 30′ to the 68th degree, and into North Greenland from the 68th degree to the most northern point. That Greenland joins the continent of America on the end of Baffin's Bay, is nearly ascertained.

The discovery of Greenland between the years 830 and 835, is mentioned in the chronicle of Snorre Sturleson, a learned Icelander, who wrote about the years 1212, or 1215. Another Danish writer, Claudius Christofferson, places the discovery in the year 770. An Icelander, Eric Raude, or Eric the Red, so called from his red hair, having killed another powerful chief of that land, was obliged to quit the country, and determined to make a voyage of discovery, a practice very common at that time. Soon after he set sail, he reached the point of a cape on the continent of Greenland, which cape he called Heriolfsnæs, in commemoration of one of his ancestors. Turning from this to the south-west, he entered a very large inlet, which he called Eric's Sound, probably the sound called by the natives Ikareseksoak, which separates Cape Farewell from the continent of Greenland; he then stopped and remained on an island in the vicinity of it. The following summer he explored the continent, and returned in the third year to Iceland, where he boasted very much of the fertility of the new country which he had discovered, to which he gave the name Greenland, hoping thereby to induce a great many people to follow him. Of 25 vessels which set out with him for Greenland, only fourteen arrived safe. These settlers were soon followed by others, both from Iceland and Norway, and their number in a very short time increased so much, that they occupied part of the east and west coast of Greenland. Eric Raude and his sons Leif and Thorstein afterwards made excursions from time to time to the opposite side of Davis Strait, or the North American coast, and founded colonies there, to which they gave the name of Winlandia. In the year 999, Leif made a voyage to Norway, and was persuaded by King Tryggegon to embrace the Christian religion; he took priests with him to Greenland, for the conversion of his countrymen; and his father, Eric Raude, with many of the people, went over to the Christian faith, and there was afterwards established a bishopric, and a great number of churches. The old Icelandic and Danish writers tell us, that there existed 12 parishes on the east coast of Greenland, containing 190 villages; and four parishes, containing 100 villages, on the western coast. The last bishop Andrew was sent there in 1408, and after that year Greenland was no more thought of for a very long time.

Amongst the foreign travellers who visited the coast of Greenland very early, about the years 1379 and 1380, were the Venetian noblemen Antonio and Nicolo Xeno, to whom we are indebted for the first map of Greenland, published, with a description of their voyage, by Francesco Marcolin, at Venice, in 1558. From the year 1408, all intercourse was cut off, and all knowledge of Greenland has been buried in oblivion. Previous to that time the Esquimaux, now called Greenlanders, began to shew themselves on the western coast. It cannot now be ascertained whether these Esquimaux, harassing incessantly the Icelandic and Norwegian settlers, have at length prevailed against them, and extirpated the whole race. Some suppose that the plague, called the black death, which devastated the north of Europe, from the year 1402 to 1404, reached this land, and carried off a great number of the settlers, so that, by their diminution, they were weakened to such a degree, that at last it became an easy matter for the Esquimaux, (called Skrællingers by the settlers) to make war upon them, and to extirpate them. In this forgotten and neglected state Greenland still remained, until the beginning of the 16th century, when a new spirit burst forth in Europe, to explore the unknown regions of the earth.

Martin Forbisher, or Frobisher, was, in the year 1576, the first that navigated this coast, and called it *Meta Incognita*. A sound which, according to him, divided that continent, was called Forbisher Strait. He was sent out again by Queen Elizabeth, in the year 1578; but he lost two of his vessels, and could find neither the sound nor the land. The Forbisher Strait is marked on all charts of Greenland, but it does not exist anywhere on the whole coast.

John Davis followed the same course, in the year 1585, and discovered that strait which now bears his name, viz. Davis Strait, which reaches to the 70th degree. Some public-spirited gentlemen sent out Robert Bylot as captain, and William Baffin as pilot, with the ship Discovery, in the year 1616: they reached Davis Strait, and advanced as far as the 77° 30′.

The Danish government, animated by these discoveries, began also to think of their lost Greenland, or the Osterbygd, (eastern settlements,) and during the reigns of seven kings, spent considerable sums upon it, but without success; the eastern coast having become inaccessible by the floating ice. Finally, in the reign of Frederic the Fourth, Hans Egede, a clergyman from Vogen, in the North of Norway, animated by a religious enthusiasm, offered himself for the conversion of the Greenlanders, and, accompanied by his wife and children, left his office, and his native country. He was furnished by the Danish government with two vessels; and, being provided with the necessary stores, he embarked on the 2d of May, in the year 1721, and, after struggling with many dangers, landed on the 3d of July, at Baal's river, in 64° 5′ of N. Lat. The Greenlanders did not like their new guests; but, by degrees, they were influenced, by friendly treatment and presents, to entertain those who visited them. The trade had a very poor appearance in the beginning, but all succeeded very well in the course of three years. From time to time, the establishments both for the mission and the trade were increased, and Mr Egede built the first European house in Baal's river, calling the settlement, metaphorically, Gotthaab (Good Hope.) The three first missionaries of the German *Unitas Fratrum*, or the Moravian Brethren, were sent out in the year 1733 They established their first settlement in the vicinity of that of Mr Egede, and gave to it the metaphorical name New Herrnhut, their first settlement in Germany being called Herrnhut, that is, protected by our Lord.

The Danish government were not discouraged by the unpromising appearance of the missions and the colonies, but made ample provision for upholding and extending them, and formed permanent settlements for the best possible cultivation of the land. Horses and soldiers were sent over to Greenland, that the settlers, by their aid, might travel over land to the east coast, or the lost Greenland; but the icy vallies, and glaciers crossing the interior of the country, were found impassable; the horses perished, and all those endeavours proved abortive. The only possible way to come there, would be with Greenlandish leather boats, which are easily transportable over the floating ice, travelling round Cape Farewell, and never losing sight of the coast. But the reports of the Greenlanders, who dwell in the most southern part of the country, give sufficient reason to suppose, that none of the old settlers will be found there; it being probable, that a coast incessantly surrounded by ice fields, which have lain there from time immemorial, and increase every year, as is ascertained by the whale-fishers, who go to Spitzbergen, will be now much colder than it was some centuries ago, when the sea was still open for sailing from Iceland and Norway, and free from floating ice during the whole summer.

The colonies and settlements existing at this time on the whole coast of West Greenland, in a line from south to north-west, are,

1. *Nennortelik*, or Bear-island, lying on the east of the promontory of Cape Farewell. The Greenlanders, who live on the remotest places in the south, come there, if the floating ice permits it, with their articles of trade, such as the skins of the blue and white fox, and of the white bear. The island is only inhabited by one Greenlandish family.

2. *Lichtenau*, the most southern establishment of the Moravian Brethren, lying in the Firth Agluitsok, in the 60° 34′ of latitude.

3. *Julianeshaab*, established in the Firth Kakortok, in the 60° 43′. In its vicinity are the ruins of an old Icelandic or Norwegian church.

4. *Fredrikshaab*, in the 62° 30′, is one of the oldest colonies, established in 1742.

5. *Fiskerness*, a Danish lodge, in the 63° 20′. Four leagues from this is,

6. *Lichtenfels*, a settlement of the Moravian Brethren, founded in the year 1754, on an island called Kikertarsoeitsiak.

7. *Godthaab*, in the 64° 5′, in Baal's river, the first settlement for the mission and trade, established in the year 1723, by Mr Hans Egede, the first missionary of Greenland. A dwelling-house of stone was built by him in the year 1726, the walls of which are three feet in thickness; it is 27 feet long, and 16 feet broad. Some hills, at the distance of one league, separate Godthaab from New Herrnhut, the first Moravian settlement in this country. The governor of South Greenland resides here.

8. *New Herrnhut*, which has also a very large dwelling-house, built of stone, by the Moravian Brethren.

9. *Zukkertoppen* (*Sugar-loaf*,) so called from a conical mountain in the vicinity of the settlement, established in 1755, in 65° 40′ North Lat.

10. *Holstein-burg*, established in 1770, in 67° 10′ North Lat. the last colony of South Greenland.

11. *Egedesminde* (that is, *Memory of Egede*) is established in honour of the first missionary, Hans Egede. It lies in 68° 40′ North Lat. on the most southern point of Disko Bay, generally called on the charts South East Bay, and Fish Bay, which is one of the most convenient places for the whale fishery.

12. *Christianshaab*; 13. *Clanshavn*; and, 14. *Jakobshavn*, in 68° 50′, are the settlements established round the continent of Disko Bay.

There are two other colonies, called, 15. *Kiokkerhuk*, and, 16. *Rittenbenk*, situated in 70° N. Lat. on islands in the Waygat, which is a sound that separates those islands from Disko island.

17. *Omenak*, another settlement, established 1768, in 70° North Lat. is situated on an island of the same name in James's Bay, which, in the English charts, is called Cornelius Bay. The most northern colony which existed, was,

18. *Upernavik*, on one of the Women Islands, 72° 32′ North Lat. although now abandoned by the settlers, for want of intercourse with, and support from, the other settlements. It is still inhabited by some Greenlanders, who have very little intercourse with the Europeans, and never venture farther to the north than to the 73d degree.

There is another settlement, *Godhavn*, on Disko island, where the governor of North Greenland resides, and two other at *Kronprinz island* and *Hund island*, called, on the charts, Whale Island. The English whale-fishers visit frequently those places. On the whole coast are five Protestant Lutheran Danish churches, where the gospel is preached both in Greenlandish and Danish; there are also three meeting-houses of the Moravian Brethren. The Lutheran churches are at Frederikshaab, Godthaab, Holsteinsburg, Jakobshavn, and Claushavn. The Moravian meeting-houses are at Lichtenau, Lichtenfels, and New Herrnhut. The Moravians have no mission farther to the north.

Greenland was always considered to be a property of the King of Denmark, the Danish flag having been hoisted there so early as in the 13th century. The trade with the Greenlanders was several times interrupted, as already mentioned, the inhabitants wishing to avoid all intercourse with foreign countries. The religious zeal of the venerable Lutheran clergyman, Hans Egede, by degrees attached the Greenlanders to the Danes: the uninterrupted communication with the Greenlanders made the Danes acquainted with the language of the country; and as the natives began to feel the want of some European articles, a commercial intercourse was established. The trade was always a monopoly, undertaken at first by a company of merchants, and afterwards conducted on account of the government. Each settlement is managed by a trader and his assistant, both of whom are paid by the government. These officers and their workmen are subjected, besides the Danish law-book, to another regulation of trade, called Instruction. The general inspection of the trade, and the administration of the laws, is placed by the king under the care of two governors, or general inspectors, one of whom resides at Godthaab in South Greenland, the other at Godhavn (Good Harbour) on Disko island. Their power is very extensive, but is restricted to the settlements; the natives being without laws, except such individuals as are in the pay of the Danish government. The trade and the navigation to the colonies is governed by the royal direction of the Greenland trade at Copenhagen. The Danish missionaries, their installations, functions, and residences, are settled by the royal Danish college for converting the heathens. The Moravian Brethren there are under the immediate direction of the *Unitas Fratrum* of Herrnhut in Germany.

The exports from Greenland are, feathers and eider-down, horns of the sea-unicorns (*Monodon Monoceros*,) skins of seals, of the blue and white foxes, white bears, white hares, and rein-deers, whale-bone and blubber, or oil of every kind.

The imports directly from Copenhagen to Greenland are, guns, powder and shot, all kinds of iron-mongery, particularly knives, files, axes, needles, nails, arrow-heads, linen and hosiery; articles of luxury for the women, such as cottons, ribbons, gloves, looking-glasses, snuff-boxes; tobacco is an article in great demand everywhere. They are also anxious to obtain rye-bread, barley, tea, coffee, beer, and brandy. The latter article, however, is strictly prohibited from being sold, or even given to any Greenlander. Every spring, in the beginning of May, five or six vessels go out from Copenhagen to Greenland with the articles of trade for the natives, and the necessaries and comforts of life for the Europeans. The cargoes of these vessels may be calculated at 65,000 rix-dollars (13,000*l.* sterling.) The value of the productions carried to Copenhagen may amount, on an average, to 85,000 rixdollars (17,000*l.* sterling.) But the communication between Greenland and Copenhagen was entirely suspended for five years, in consequence of the war between Great Britain and Denmark. The buildings and stores of the Greenland company have suffered very much, from not having been repaired, in consequence of the want of timber and other materials; and it is now supposed that the establishments will be reduced to a smaller scale.

The natives inhabiting the western coast of Greenland, from the 59th degree to the highest north, belong to the Mongolic race of mankind. They are called Skrællingar by the old Icelanders and Norwegians, on account of their little stature; but they call themselves, in their own language, Innuit, that is, men or human beings, in opposition to other creatures, and this not from presumption. They are called Esquimaux, or Eskimos, by some authors. They speak the same language as the inhabitants of Labrador and part of Hudson's Bay, and their mode of living is very similar. They are probably spread over Behring's Strait, and part of Nootka and William's Sound, as it appears from the maps of the late Captain Cook, where some islands are marked with names used by the Greenlanders in Davis Strait. They resemble one another in their stature, their complexion, and their customs. Living under a rigorous climate, which presents very few productions, the size of their bodies is reduced by the nature and scarcity of their food, and the extreme cold. Although the stature of the Greenlanders is in general below the common standard, their persons are not proportionably slender, being usually pretty plump, but very seldom muscular. Their face is large and broad, the nose not very flat, but small and short; the nostrils somewhat wide, the cheek bones high, the cheeks round and plump. The face frequently appears fallen in quite across between the temples. The forehead is low, the eyes little and black, dull and drooping, but having the power to distinguish accurately at a very great distance. The eyelids are drawn towards the temple; the mouth is generally little, and round; the teeth very regular, and beautifully white; the lips thick, and turned outwards; the under lip somewhat thicker than the upper. The beards and eyebrows are thin, but they have abundance of hair on their head, which is black, long, coarse, and straight. Their necks are short, their legs thin, but their feet and hands are small and very well formed; their heads are uncommonly large. The shape of the women is very similar to that of the men, and they resemble them so nearly, that one cannot at first distinguish the sexes, their dresses being nearly the same. The appearance of the women is by no means feminine; they have high breasts and broad shoulders, being accustomed, when very young, to labour hard, and carry great burdens. The Greenlanders are of a yellowish grey colour, which approaches somewhat to olive green; but this may be attributed not only to the climate, but to their dirty habits, and to the great quantity of smoke and soot which their houses contain; for their children are born as white as any European child.

The oily nature of their food contributes probably somewhat to deepen their colour; their blood becoming so dark, dense, warm, and oily, that their skin has the smell of oil, and their hands and feet are as clammy as bacon. Their bodies being very fleshy and fat, and coated as it were with a varnish of oil and dirt, they can bear the cold better than an European. They sit commonly naked in their houses; and the effluvia from their bodies is such, that an European who sits by them can scarcely endure it. Their children are in general very healthy; and one rarely sees among them a human being mis-shapen from its birth. They consider themselves to be very well educated and informed; and when they meet together, nothing is so customary among them as to ridicule the Europeans and their manners. The women, in particular, understand that sort of humour extremely well. They use a mode of very expressive mimicry, consisting of certain grimaces, by means of which they can make themselves understood from one corner of the house to the other; and a European coming to their country will instantly be characterised by a nickname, expressive of his manners, or behaviour, or personal defects. They reckon themselves the most modest people in the world: and seeing a modest foreigner, they say, *innucksisimavok*, or *innungorpok*, that is, "he is as modest as a Greenlander." Although there may be some presumption in this, yet it cannot be denied, that they are modest, friendly, and not litigious: generally compliant; but, when exasperated, they are so desperate, that no danger deters them from their revenge. Although very ignorant, they are by no means stupid. They learn easily to read and to write their language, not only the children, but also men advanced to twenty and thirty years of age. Some of them, besides their maternal tongue, speak Danish very well, and they have a great inclination to mechanics. As their supply of food is but precarious, their patience in hunger is astonishing. Their strength, in proportion to the size of their bodies, is not less wonderful. Pinched with hunger for some days, the man is nevertheless able to row out, and to manage his kajak in the most boisterous sea.

Their manner of clothing is quite correspondent to the climate. Men, women, and children, from the time they are three years old, are cloathed nearly in the same manner. Their ordinary dress is a sort of close frock, or rather robe, which reaches to the knees. It has at the upper part a round hole, sufficient to put the head through, and not large enough to admit the cold. The sleeves are rather wide on the shoulders, becoming narrower as they reach the wrists. A hood similar in shape to the cowl used by monks, is attached to the back of the frock. This is drawn over the head in winter or bad weather. In warm weather they generally walk bareheaded. Some of them now use the round hats of the Europeans. Their breeches are nearly like those of Europeans. Their stockings are in summer of seal-skin, in winter of dog or rein-deer skin; and those of the women are of fowl-skin. Their boots are made in a very neat and ingenious manner; sometimes of seal skin, sometimes of rein-deer skin. The frocks are also made of seal or rein-deer skin. At the seams, where the different skins are sewed together, they are usually adorned with narrow thongs of differeut skin, sometimes coloured red; they are worn with the hairy side outwards. In cold weather they use under the frock a shirt made of fowl-skin, of the *Alca pica*, or *Anas mollissima* or *Pelicanus carbo*.

When at sea in their small canoes (called *kajak*), they use a sort of frock impenetrable to water, with the hair taken away, called *Erysak*. The bottom part is fastened round a ring or hoop made of bone; and this hoop is joined to the hole in which the Greenlander sits, so that no water can penetrate it. They have also another frock made very ingeniously from the intestines of whales, dolphins, or seals, prepared with such skill as to resemble, in a great measure, our goldbeater's leaf. The clothes of the women differ very little from those of the men. The sleeves are very high and wide on the shoulder, and reach only to the elbow. They are cut out downwards from the top of the thigh, and form a long tongue-formed flap both behind and before, the end of which reaches to the knee. It is very carefully sewed, and bordered round the body with narrow thongs of white or coloured leather, sometimes of red cloth. They wear breeches, with very short drawers underneath. Their common boots are made of black or brown seal-skin, their dress boots of white or red coloured seal-skin, reaching over the knees. Shoes are rarely used either by the men or women.

They live in winter in houses, and in summer in tents. When the summer is over, which is generally at the end of August, the women belonging to the family or to the house are very busy in repairing an old or in building a new house. It is done in a very few days; and this labour resembles the liveliness of an ant-hill. Some carry stones, others bring sod; several turf, timber, shrubs, or earth. The walls are made of water-worn stones, put together with turf or sod instead of mortar; and the roof is formed of pieces of floating timber. It is flat, and is covered with shrubs, turf or sod, and earth. The stones are taken from the shores, as they never build a house at a greater distance from the sea than 20 or 30 paces; the timbers are picked up from the sea during the summer. Their houses are sometimes regular, sometimes oblong squares; being from 12 to 18 feet in length, and from 10 to 12 feet in breadth. The height is generally six feet. The walls are at their base two feet, and on the top one foot thick. The entrance is usually under the earth, two feet high, two feet broad, and from 12 to 15 feet long. It is in the centre of the house, and generally faces the south. The house has no door, and one must always creep in on hands and feet. Above the entrance is one, and sometimes two windows, which are made of the intestines of whales, or dolphins, or seals, sewed together. The house consists of only one room, at the back of which there is a kind of stage, raised from one foot to one and a half from the ground, and extending the whole length of the house. It is covered with seal-skin, and is used as bench, chair, table, and bed-stead. Being divided in the front by perpendicular standing timbers, it has the appearance of low cow-sheds or stables, separated by skins. Each family occupies such a division. They sit on this bench the whole day, the men with their legs hanging down, the women generally cross-legged. Each family has at least one burning lamp, made by the Greenlanders themselves of pot-stone. All round the margin of the vessel oiled moss is placed, which serves instead of a wick; and the vessel contains about a quart of oil. The lamp serves them as candle, chimney, and cooking fire; and is attended by the women. On the roof of the house, over the lamps, are racks for the purpose of drying clothes, boots, gloves, &c. The extremities of the large bench on both sides of the house are considered to be the best places, being most removed from the entrance, and therefore given to the first women of the house, or to travellers of distinction. A narrow bench runs along on both sides, and under the windows of the house; and in this place strangers of less consideration sit and sleep. The houses are very well heated, and the heat is increased by the uncommon evaporation of the natives. A European is obliged to go out occasionally, to get fresh air. The interior of their houses looks very well at the beginning of the winter, as long as any degree of order exists in them. But this is over in a very short time; and even this irregularity and confusion is exceeded by their nastiness and stench. They not only keep a number of dead seals, fowls, &c. in their warm houses, but they also gut them there. This, together with the bones, and rotten or half eaten fragments of boiled and raw flesh, occasions several heaps of filth, which are never removed, till, from their bulk, it becomes troublesome to pass over them. Every thing about the house smells of train oil and smoke; and every part of it is as filthy as can be imagined. It is revolting to Europeans to see their dirty hands and faces, almost always dripping oil; their meat dressed and eaten in such a disgusting manner; and their nasty clothes, literally alive with vermin. They are also very dirty in cooking their meat; they seldom wash a vessel; the colour and the odour of the last dish must remove that of a former one. They lay their boiled meat in wooden dishes of fir wood, made by themselves, which are never cleaned; and first drink the soup, or eat it with spoons made of bones or wood. Their undressed meat lies on the bare ground, or on an old seal-skin. They have no determined time for dinner or supper; but when the men of the house return with the game, which generally happens in the evening, part of the day's spoil is immediately boiled, and all the people who live in the neighbourhood are invited.

The men get their meal first, sitting upon the ground, round a large wooden dish, and taking the meat with their fingers. When this is over, the women begin in the same stile, but at the opposite end of the house. If there be a European guest, or any other stranger, the woman of the house takes a piece from the kettle, licks it clean from blood and scum, and presents it to him with her own hands. It would be considered a high degree of impoliteness to decline it.

Their time of removing from their houses to their tents is not exactly fixed. It takes place generally at the end of April, or in the middle of May, as the snow melts sooner or later; and it frequently happens that part of the badly supported roof of the house gives way and falls down, an accident which forces them to remove to the summer place. The tents are larger and smaller, in proportion to the size of the family and its fortune, but rarely exceeding the length of 12 feet, and the breadth of 10 feet. A wall one foot high is first made of stones and sods, on which they rest the poles, which form an acute angled triangle with the ground. The poles are then covered with seal-skin; and a curtain is placed before the entrance, made from the intestines of the whale, dolphin, or seal. The bed-places are similar to those in their houses. The tents are, like the houses, near the shore, as the sea supplies them with all their wants, and the seal provides them with all the necessaries of life. The instruments to procure their food are very simple, but they are admirably adapted to their purpose. The principal of them is the harpoon, called *erneinek*, and *unnereek*, which is the largest of them all, being two yards and a half in length. The second is the lance, called *angoviak;* the third a smaller lance, is called *kapput:* these three are generally used for seal-game, the first to attack, the two others to kill the animal. The first was also formerly used to attack the whale; but now the Greenlanders do it in the European manner, with large harpoons. A fourth instrument, called *akligak*, is a kind of javelin with a head of iron, barbed, to prevent its becoming disengaged from the animal. It is generally used when they pursue their game in company. For catching birds, they use the *nugit*, or fowling-pike, headed with iron like the last, and furnished, towards the middle of the shaft, with three notched forks made of bone, that one of these may reach the bird, if he escapes the apex, which is of iron. For land-game they formerly used the common Indian bow, with its arrows made of fir, and stiffened with sinews of animals, with a string likewise made of sinews; but the use of it was nearly abolished on their being provided with guns by the Europeans: although they were obliged, during the time of the late war, to resort to their old method of shooting, which succeeded very badly, from the want of that dexterity which they formerly possessed. The Greenlanders being a very pacific people, none of the dreadful instruments of war used by other Indians are found among them. They use for fishing the same apparatus as other nations, the lines being generally made of very thinly shaved thongs of whalebone.

Their canoes are of two different sorts; the one large and open, the other small and covered. The framing of both consists of slender pieces of wood, covered on the outside with skins of seal sewed together. The wooden framing is joined by thongs, cut from seal-skins, or by thinly shaved whalebone. This manner of putting them together, gives to the canoes so great a degree of flexibility, or rather elasticity, that they very seldom can go to pieces even in the most boisterous sea. The large canoe, called umiak, or the canoe for women, is generally twenty-four or thirty feet long, four or five feet wide, and two or three feet deep, terminating acutely at both ends. The bottom is flat. It is used in summer to transport the whole family, and its utensils and tent, from one place to another; and is in the evening always taken up on land, in order to be dried, repaired, and varnished on the outside with old thick rancid oil, called Minnek, to prevent the water from penetrating the seams.

The other small canoe is called kajak, and is only used by the men; it is sharp at both ends, and its entire shape and appearance is not unlike a weaver's shuttle. It is from four to five yards in length from one extremity to the other, about a foot and a half wide in the middle, and scarcely one foot in depth. In its centre is a round hole, with a prominent ring of bone or wood, in which the man seats himself, and fastens the under part of his frock round that ring, forming thus one body with his canoe. Upon his kajak he has his instruments, striking the sea alternately on both sides with a paddle called pautik, four fingers broad at each end. He can row in a very boisterous sea, and if overturned by the billows, he is able to raise himself again. All their sea game is procured in these small boats. The boy is employed by his father in his earliest age, that is, in his sixth or seventh year, to prepare himself to perform the business of a man. The first sea-fowl caught by a boy gives occasion to a great festival, and dinner of the family, for the purpose of doing homage to the rising master of the house. Another kind of sea-amusement, or rather ice-amusement, is used in winter, in the north of Greenland, from the 70th degree to the highest northern latitude, by means of sledges drawn by 6 to 12 dogs. The Greenlanders drive them over the frozen sea, a distance of 50 and sometimes more miles from the lands, to the rifts and clifts of the ice, and catch there the dolphins, sea-unicorns, and seals, which come there in great numbers to take air. The spoil is carried home by the assistance of the sledges. The velocity of the dogs is astonishing; they may be driven 100 miles in 9 or 10 hours.

The men take no charge of any of the domestic operations. The women must make clothes, boots, canoes, and tents, dress leather, clean and dry clothes and boots, gut and dismember the spoil, cook the meat, cut the pot-stone-lamps, prepare oil and wicks, and build houses and tents. The girls are employed to this business from the time they are twelve years old. The boys are, from their first childhood, regarded as the future masters of the house. The Greenlanders never strike their children, who are very untractable until their sixth and seventh year; afterwards they follow their parents very willingly, and shew with their increasing age a still more respectful behaviour towards them.

The men seldom marry before the twentieth year of their age; and the women in their seventeenth or eighteenth year. The bridegroom never concerns himself about marriage-dowry; he is well satisfied if his bride understands housewifery; that is, all the business which we have already mentioned as belonging to the female. The parents never interfere, but they always wish that their son-in-law should be a good hunter; and on the other hand, that the wife should understand housewifery. The girl always makes great difficulties, runs to the mountains, or cries *pro forma*, and the bridegroom generally takes her by force from the house of her parents, and puts her, supported by some old women, in his umiak, which is lying on shore. He brings her to his house, and they are considered as married. They never marry their relations. Polygamy is not very common among the unconverted, and is strongly prohibited among the baptized. It occurs, however, though very rarely, that a heathen has three or four wives. The most respected of them is she who is so fortunate as to have boys. They are not very prolific, the number of children seldom exceeding five or six. If a wife has no children, she herself often requests the man to take a second wife, it being thought ignominious among them not to have a family. The second and third wife is always inferior in rank to the first. Their marriages are not indissoluble; the man sometimes puts his wife away, and the wife also occasionally elopes, and generally retires to her parents, if she is not satisfied with the man, or with his conduct. The women bring forth their children very easily, and perform their usual business in the house to the last moment, and go out again the day after the delivery; they are assisted in the delivery by some old women, as many as there are in the neighbourhood; they rarely bring forth a child before the proper time; the birth of a child is always followed by a dinner. As the people are not very prolific, the coast is very thinly inhabited; the population of which was stated to have been about 20,000 souls, on the arrival of the first missionary, Mr Hans Egede. The small-pox, carried hither from Europe in the year 1733, swept away more than 3000 souls. Other diseases diminished the number of the natives from time to time very much, which, according to the latest accounts given by the governors and missionaries, does not surpass the number of 7000 on the whole coast, from the 60° to the 73° of Latitude. Venereal diseases are unknown. It is a curious circumstance, that the fruitfulness of the native women increases, when they are married to Europeans. This is still perceptible at this day in Greenlandish families, mixed with Europeans at the time of the first mission (1721), the European features being still visible.

The Greenlanders are very sociable; although they do not live in towns or villages, they like to visit and to be visited. A man or woman never pays a visit to a person residing at a distance, without making some present at the house she visits, either a skin or fowl, or some sinew. They are very fond of making bargains, and often part with their most useful utensils in exchange for trifles, particularly to satisfy the capricious frivolity of their wives. No one desires to usurp any authority over another, to make regulations for him, or to call him to account for his actions; for, as they have no riches, one individual supports another; the helpless finds refuge in the house of the more fortunate, without being related to him, and each Greenlander has his landed property where he resides. They may therefore change their residences as often as they like. Whatever the sea drives on shore, particularly floating timber, is the property of him who has taken it up, and brought it on shore. Notwithstanding, however, their honesty towards each other, they are not scrupulous in stealing from Europeans.

It is very singlar, that the heathens inhabiting this country, have no worship. It was believed by some navigators, who saw the Greenlanders observing the rising sun in the morning, that this people worshipped the sun. They were confirmed in their opinion by the squares of stones, which they saw erected for the purpose of their tents, and supposed that they were places of worship; but they have no religion at all, although they are not without some notion of a Divine Being, and of a future state.

They frequently speak of a supreme Being, called by them Tornarsuk, a compound of bad and good, probably a remnant of the religion of the old Norwegians. He is the oracle of the Angekut, or Greenlandish philosophers, (if this word may be so improperly used,) who are alone admitted to have intercourse with that great spirit. Besides Tornarsuk, they speak of many inferior beings or spirits residing in every corner of their country. Each Greenlander may become an angekok or sorcerer, if he will submit to certain trials and ceremonies; but the angekok never enjoys any peculiar veneration from the Greenlanders. He profits by the superstitious credulity of his countrymen, pretending to cure the sick with magic art, and presenting amulets of seals, rein-deers, &c. as a preservative to those in health. The angekut have their peculiar kind of language, a kirendum or jargon, understood only by themselves.

The Greenland language might with more propriety be called the language of the Esquimaux, as it is spoken by the Esquimaux in Labrador, on the shores of Hudson's Bay, and in various other places of that coast, the Greenlanders being only part of that nation. It probably also extends to Behring's Strait, Nootka Sound, and William's Sound, and has no affinity to any of the other north Indian languages, as far as they are known. There is but little variation in the dialect on the coast of Greenland, but in the south it is spoken in a more singing tone. The letters *b*, *d*, *g*, *h*, *l*, *v*, are never used in the beginning of a word; the letters *c*, *f*, *q*, *x*, and *z*, are not used in their language. It abounds with double consonants, particularly *k*, and *r*, and is very guttural. The language is made extremely difficult, in consequence of the great number of polysyllables, by the use of which a whole sentence is put together in an elliptical manner. They have very few adjectives, and use the participles of the verb to supply their place. In the language are a great number of *affixa verbalia*, by the use of which an astonishing variety is produced in the signification of their verbs. Thus from the radical verb, *innuvok*, "he lives, is a man," is derived *innugikpok*, "he is a handsome man;" *innurdlukpok*, "he is a mis-shapen man;" *innukulukpok*, "he is an unfortunate man;" *innuksiorpok*, "he is a good man;" *innukpilukpok*, "he is a bad man;" *innuksisimavok*, "he is a man as a Greenlander, (a modest man;") *innungorpok*, "he begins to be a Greenlander." The third person *singularis præsentis* is its radix. Every verb has its corresponding negative, formed by the addition *ngilak* to the radix, thus: *pekkarpok*, "he has," *pekkangilak*, "he has not." Each flexible word has its dual, ending with the letter *k*; the plural ends with *t*; thus, *nuna*, "land, country;" *nunæk*, "two countries;" *nunæt*, "countries." The articles, pronouns, and prepositions, are formed by suffixes, changing the termination of the noun thus: *nalegak*, "master, lord; *nalegama*, "my lord;" *arnak*, "mother;" *arnamut*, "to the mother." A great number of augmentatives and diminutives are also formed, by varying and adding to the termination; and this circumstance contributes to make the language agreeable and expressive. Thus, *kikertak*, "island;" *kikertangoak*, "a small island;" *kikertarsoak*, "a large island;" *kikerteitsiak*, "a fine island;" *kertarsoeitsiak*, "a large fine island." Their numerals are limited to five. They express numbers from six to twenty, with the help of addition. Thus; five and one, five and two: twenty is expressed by *innùk*, man; that is, 10 fingers and 10 toes; numbers exceeding 20 are generally called innumerable.

They have no traditions from their ancestors, except an incongruous account of their battles with the old Norwegians; the history of the Greenlanders is therefore buried in impenetrable darkness. They have no chronology, no one can tell his age; but they are well acquainted with the north star. The angekut call the ursa minor *asellut* in the south, and *kuttak* in north Greenland, the ursa major *tukto*, or *rein-deer*. They divide the day according to the tide, and reckon their years by winters. The distance of 32 miles, from one place to another, is called one day's voyage, (made with a canoe.) The different seasons are marked by the migration of birds, fishes, and other animals which regularly visit their coast.

The angekut are somewhat acquainted with physics, particularly meteorology; they observe the weather with great attention, and from the state of the atmosphere they make very accurate conclusions respecting its changes, even at a distance of three or four days; and as the natives procure their food from the sea, this habit is of great importance to them. The angekut are also the physicians of their countrymen, and prescribe generally a certain diet, as most of the diseases result from their very irregular mode of living. If diet is ineffectual, amulets are applied, presented in bones of different animals, particularly of rein-deers and seals. The most common diseases are eruptions of the skin; one is a sort of small pimple, which in a very short time covers the whole body; the best remedy is to drink a decoction of *ledum groenlandicum*. The other is a kind of leprosy, which infects their whole body with cancerous boils and scurf. Those who are afflicted with it, are abandoned by their relations, and die in the greatest misery. The smallpox and measles were formerly unknown to them, but were conveyed from time to time by European vessels to these poor people, and committed dreadful devastations. These diseases are mortal to the Greenlanders, their skins being so dirty and oily as to prevent the eruption. In the year 1733, the first year of the mission, 3000 people died of the smallpox. But vaccination is now employed by the Danish government with great success. All the other diseases which arise, where the air is condensed by cold, and perspiration is obstructed, are very common in Greenland. A wounded or fractured limb is cured very quickly by themselves, but they have no remedies for internal diseases, such as consumption, blood-spitting, pleurisy and diarrhœa. Scurvy is not very common amongst them, as they do not use salt meat or fish. The want of food, to which they frequently are exposed in winter, produces very serious complaints, which are particularly perceptible in the following spring. It frequently happens in winter, when the frozen sea refuses the necessary supply to the wretched family, when the last thong of leather is swallowed up, and when there is no longer oil to burn in their lamps, that the hunter returns with an animal, and some of these poor creatures devour the raw or half-boiled meat, and falling victims to the indulgence of their appetite, instantly die of indigestion.

They bury their dead generally on a small hill, in a sitting posture, dressed in their best clothes, and covered with seal-skin. The land being a mass of rocks, the inhabitants are obliged to build graves of stone, which are covered with plates of mica slate, or clay slate, to prevent carnivorous animals from destroying the bodies. Their kajaks (canoes), instruments, and utensils, are placed by the side of the grave. They return from the burial-place to the house of the deceased, to continue the lamentation, which consists of a dreadful monotonous howling, supported by all the attendants, who sit with their faces turned to the ground. When this is over, some refreshment is taken, and each returns to his own house.

The whole coast of Greenland, receiving the beams of the sun in a very oblique direction, is deprived of that general comfort which other parts of the earth enjoy. The soil being shallow, is frozen during the greater part of the year; and the ice having taken possession of all the vallies of this barren and rocky land, the winds which blow over these are, even in summer, extremely cold. The prevailing winds are those from the east and north-east, north-west and north. The cold which the north-eastern wind brings in winter is almost insupportable; and the thermometer is very often at —35° or 36° of Reaumur (—48° of Fahrenheit). The winds which blow directly from the sea (Davis Strait), are moist and generally attended with rains, in winter with snow and sleet; and are more boisterous in spring and autumn than in other seasons. Winds reflected from the mountains, and striking through the vallies with great violence, are extremely dangerous to vessels sailing near the coast. Strong stormy winds from the W. or S.W. always break the sea-ice even in the middle of winter. The cold sets in with the month of January, accompanied with but little snow, which generally falls either before or after that time. More snow falls in the south than in the north. The sea does not freeze before the beginning of January, forming thus on its surface clammy spherical concretions, which increase rapidly, and as they join together, present a crust of the thickness of an inch in a very few hours. This coagulation only takes place when the sea is calm. Previous to that operation of nature, the sea smokes, like burning turf-land; and a fog or mist arises, called *frost-smoke*. This cutting mist frequently raises blisters on the face and hands, and is very pernicious to the health. It appears to consist of small particles of ice, and produces the sensation of needles pricking the skin. The same icy particles carried up by the wind, cause probably another phenomenon which is frequently seen in winter round the moon, a ring of light, or halo, called by the Greenlanders *Illuparosek*; this ring appears at a great distance from the moon, and has a fine pearly lustre. It is seen at a time when the horizon is quite clear, and every star may be distinguished. Mock suns are also very frequently seen in this country, but only in winter. In January 1809, six were observed at the same time, all of a pale yellow colour. The remotest was paler than the others.—See Halo.

Of all the phenomena peculiar to this country, the aurora borealis is the most beautiful. It streams here with peculiar lustre, and with a variety of colours, which having great brilliancy, sometimes dart their sportive fire, and fill the whole horizon with the most beautiful tints of the rainbow. They are very rarely observed in the north of the horizon, commonly in the east and in the zenith. They appear sometimes to stand very low, and then they are much agitated, and a crashing and crackling sound is heard like that of an electric spark, or of the falling hail. They are more frequent and more powerful from the 60th to the 67th degree than in higher latitudes. The Greenlanders believe, that they are the souls of the deceased fighting together in the air.

Another very curious optical phenomenon presents itself, partly in clear, partly in thin foggy weather. The islands lying at a distance from the continent appear to approach to the spectator, and to increase in size. They form to the eye various and peculiar groups, very different from their proper shape. At other moments they appear to hang in the air. If this phenomenon appears with respect to the islands which lie in the south, southerly winds will follow; if the object be in the west, westerly winds may be expected. The winds decrease generally after sunset.

Fire-balls are rarely seen in this country, although one was observed in the year 1808, taking a direction from north-west to south-east. The comet of 1807 was first observed on the 4th of October, in the north-west; and that of 1811 on the 4th of September, in the north, and disappeared the 14th January. Thunder is very seldom heard, but sometimes flashes of lightning are seen. The air is extremely pure and light; the rains are not of long continuance; and the heat, particularly in the inlets, is astonishing, being caused principally by the reflection of the solar beams from the mountains. The saline particles of the sea-water are frequently found crystallised on the shores. In the month of July, the thermometer of Reaumur rises in the shade to 24 degrees, (86° of Fahrenheit). The moskitos (*culex pipiens*) are at that time as painful and troublesome as in a southern climate.

The ice, which embarrasses the polar regions, and disturbs the navigation, is of different kinds, some of it being of fresh water, some of salt water. The former is clear, very hard, brittle, having an appearance entirely glassy, and presenting sometimes colours of the finest pale emerald green, or the brightest sky-blue; when cut in pieces, the fragments are as sharp edged as those of rock crystal. The ice of salt water has the appearance of frozen snow, is greyish white, not transparent, and has generally a clammy coherency; when very thin, it is flexible to a certain degree, under the step of a man. It coagulates in small spheroidal particles; whereas that of fresh water presents rather acicular and prismatic forms. The fresh-water ice forms tremendous masses and mountains of different magnitudes, and wonderful shapes, sometimes rising more than 500 feet over the surface of the water. The salt ice occurs always in flakes, called by the mariners ice fields, sometimes of many thousand fathoms in length and breadth, divided by fissures, but following close to each other. These flakes of driving ice are not found so large in Davis Straits, as between the east coast of Greenland and Spitzbergen. The surface of the salt ice is generally covered with a crystalline crust, deposited by hoar frost or snow; it has a mealy or sandy surface, and becomes brackish by the tides. The salt ice never forms large mountains. On the shores, however, where the sea freezes, the mass becomes enlarged by the effect of the tides, and by stormy weather, which breaks the ice, and heaps it up.

Ice mountains are formed, during a series of years, in the inlets and bays, in valleys, or on precipitous rocks reaching to the sea. As they melt in summer at the base, where they are in contact with the rock, they get rift; and at last, losing their points of support, they plunge into the sea with a thundering noise; an awful and imposing spectacle, which may be seen in the Ice Bay, near Disko island, particularly at the time of the tides. These mountains very often enclose vegetable substances, earth, and stones; and are sometimes so large as to reach to the bottom of the sea, a depth of more than 300 fathoms, until they lose somewhat of their mass, and roll over. Immense masses of ice are driven out from the Ice Bay in the tides, at the time of high water, covering the sea of Disko Bay, to a distance of many miles.

The driving ice which comes from Spitzbergen, is generally seen at Cape Farewell in the month of May, setting over to the eastern coast of Davis Straits; but it returns again with south-west and west winds, filling all the bays and inlets of the south of Greenland, and is again thrown out from the land by the easterly winds. This ice is always followed by impenetrable fogs; a circumstance, which makes it much more dangerous to navigators. The specific gravity of the ice depends upon its density or porosity.

The floating timber, mostly pine, which comes with the ice round Cape Farewell, affords great relief both to the poor Greenlanders and the European settlers. It furnishes materials to the natives to roof their houses, to support their tents, to strengthen their canoes, to shaft their instruments, and to prepare their utensils. It supplies the Europeans with building materials and fuel. It is very difficult to say from what country these timbers come; undoubtedly from a very remote land, washed away from shores covered with forests. The timber is always much injured, generally without bark or roots, and great part of it is worm-eaten by the *Pholas teredo*, (*Teredo navalis*, Lin.) It is mostly found in the small bays of those islands which are nearest to the open sea.

The continent of Greenland is surrounded by many thousand islands of different sizes, upon which the Greenlanders generally reside, on account of their good situation for sea-game. The continent of Greenland itself is intersected by innumerable bays, inlets, and firths, many of them 100 miles in length. Their direction is generally from south-west to north-east; and some reach as far as the tremendous glacier which covers uninterruptedly the middle of the continent, and separates the east coast from the west. The connection of these firths with the large continental ice causes the numerous ice-mountains which plunge down in the summer, and are driven by the currents into the open sea. The most remarkable of the firths are, 1. *Tunugliarbik*, and 2. *Ikareseksoak*, both in the 60th degree of latitude; these reach to the glacier, and are generally full of floating ice. 3. *Sermiliarsuk*, the same firth or bay which is marked on the charts with the name Forbisher or Frobisher Strait, but falsely, as this bay extends to the great continental glacier, which surrounds it. 4. *Baal's River*, one of the largest firths, is divided into several branches by large islands. 5 *Nerusutok*, remarkable for its violent currents. 6. *Sermilik* or *Icefiord*, a firth, which presents the largest ice mountains on the whole coast. It is supposed to have been formerly a sound, which divided the continent, but is now shut up by ice. 7. *Omenaks Bay*, called *St. James Bay* and *Cornelius Bay* on the English and Dutch charts, which is the most extensive firth on the whole coast, and contains more than twenty islands. It is situated in the 71° of latitude, and in all its different branches is connected with the large glacier. 8. *Kangerdluarsursoak*, in Baffin's Bay, called *Horn's Sound* on the charts, in the 74° of latitude, is likewise a most dreadful firth, on account of its monstrous masses of ice. In the months of May and June, the Greenlanders visit the firths, to provide themselves with a kind of small fish, the *salmo arcticus*, Fabricii, (*clupea villosa*, Mulleri,) which visits the firths in millions at that season. They are dried in the sun on the rocks, and used instead of bread. They are the principal food of the seal in summer, and followed by them in great numbers. Seals are also caught here.

The *rivers* are neither numerous nor large. They can have but a small supply in that desolate region, where the valleys are covered with eternal ice, which does not melt frequently, and then only on the surface. In the vallies between precipitous mountains, there are occasionally very large lakes, which have their origin from the melting of the ice and snow on the mountains, and are confined by the rocky bottom of the valley. The springs and rivulets which come from the mountains, rapid as they are in the spring, generally dry up in summer. The inundation of these rivers in the spring, makes the soil marshy, and produces good vegetation on the shores of the firths. The old Norwegians and Icelanders formerly made all their settlements in such situations.

What are called *springs* by the Greenlanders, frequently consist only of ice-water, forced out of its accustomed channels by the power of the waterfalls running through the ruins of destroyed rocks. There are, however, some spring wells, one of which is very remarkable, from its rising and falling with the tide, although it is situated more than 36 feet above the level of the sea. Its water is not brackish, perhaps from the circumstance of its being filtered in passing through a bed of very fine sand. The most interesting is a warm spring on the island Ounartok, which has a temperature of 32° of Reaumur (104° Fahrenheit) at all seasons. It is situated on the south-east of the coast, in the 60°.

*The streams or currents of the sea* have an easterly direction, and are in some places very rapid and dangerous, particularly during high tides. It is supposed that these currents are produced partly by the unevenness of the bottom of the sea, and partly by the numerous islands, which increase the rapidity of the currents by diminishing their channels. The obstacles, which rise from the bottom of the sea, may assist in producing back currents and whirlpools. One of the most dangerous whirlpools exists at the mouth of a Firth, (called by the natives Puiosortok,) in the south-east of Greenland.

*The water of the sea* near the shores, is less salt than that at some distance from them, the former being always in contact and communication with the ice-water. *The rising of the tides* is very unequal, in consequence of the number of islands through which the tide passes. They rise in the south (from 60° to 64° of N. Lat.) to eleven feet, and decrease gradually in the north of Davis Strait (74°,) where they do not rise more than four and six feet. The highest flood is the third day after new moon, and the third day after full moon. The Icefiord, or Sermilik, in Disko Bay, has flood, but no ebb. Greenland, from its most southern point to its most northern extremity, consists of insulated rocky mountains and sharp acuminated cliffs, separated by narrow valleys, which are rendered inaccessible by the glaciers. These places never enjoy the rays of the sun, and are mostly intersected by rapid torrents, which precipitate themselves from the mural cliffs of the mountains. Ice and snow accumulate here in dreadful masses, and fill the spaces with increasing devastation. Even the Greenlanders, so accustomed to the horrors of nature, call some of these spots places of desolation. The water, converted into ice, splits the rocks with mighty force, which are precipitated from the summits with thundering noise in the summer, threatening death to the wanderer. The mountains themselves are covered with a mourning veil of black lichens, variegated here and there with spots of crumbling snow, which, being dissolved by sun and rain, run in small torrents along the precipice. The view of the valleys watered by the inlets and firths is more agreeable, and presents the entire vegetation of that deserted country.

*The small islands* which surround the continent, are generally of a different character, forming small roundish elevations or hills, the base of which is inhabited by innumerable sea fowls, which breed there at the return of spring. The large islands are similar to the continent, and consist of barren insurmountable rocks, the valleys of which are filled with eternal ice. Amongst the largest are particularly remarkable: 1st, Cape Farewell, called by the Greenlanders Kangekkyadlek, that is, the cape running towards the west. The entire island, which turns from west to east and south-east, has the name Sermesok, or Iceland, its narrow and dreadful valleys being always covered with ice. It has very little low land, and is therefore very seldom visited in summer by the natives. No family lives there in winter; but the ruins of old houses on the west side, shew that it was formerly inhabited. The most eastern islands nearest to Sermesok, or Cape Farewell, are Omenak and Cangersoak: The latter is called Statenhuk by the navigators, and both are uninhabited. In the east of Kangersoak, or Statenhuk, are more than 100 small islands called Kittiksorsoit. The Greenlanders of the neighbourhood visit these islands in the beginning of spring, to procure seal game, which is there very plentiful. The large islands, which form the promontory of the southern coast, extend 1½° from the west to the south, and are separated from the continent of Greenland by a sound of five English miles in breadth, called Ikareseksoak, through which runs a very rapid current. The sound is generally filled with immense flat masses of floating ice, and innumerable ice mountains, which are driven out from the inlets and firths of that continent. Many vessels have been beset in this floating ice by currents from north-east, and have been lost on the coast. From this, a series of small islands border the continent as far as the 61° 21′, where the eye is terrified by another island, barren, precipitous, and of considerable extent. It presents so dreadful a view, that the older navigators, although accustomed to dangers and terrors, called it the *Cape of Desolation*. This cape, which reaches far to the open sea of Davis Strait, is always intrenched by floating ice to a great distance. The island is called by the natives *Nunarsoit*, that is, a great land, and is separated from the continent by a narrow sound called *Torsukatek*. It is uninhabited, and even the Greenlanders but seldom visit it. There is no island of importance between this place and the 64°, where Baal's river falls into the ocean. This river, or rather this firth, is one of the largest on the whole coast. It extends 64 English miles to the interior of the continent, and then divides into two arms, one of which runs towards the north-east, the other towards the south-east. Both arms are bounded by the glacier. In this firth are three large islands, *Sermitsiak*, *Kikertarsoak*, and *Karosut*, the first of which consists of one large and high mountain, called Saddle by the Danes, from its saddle-shaped top. It is seen at a distance of thirty leagues from the coast. Another large island (called *Omenak* by the Greenlanders, and *Kin of Saal*, or *Zaal*, on the charts) is situated in the 65°, and being easily distinguished by its conical form, which resembles a sugar-loaf, it serves as a landmark to navigators. No large island occurs until the 69° 14′, where the *Island Disko* is situated. It is the largest on the whole coast, its length from the north to the south occupying one degree of latitude. It forms (with the continent) Disko Bay, called Fish Bay on the charts, and is separated from Greenland by a narrow strait called Waygat. It is uninhabited, except by the Danish settlement called Godhavn, which is established in Love Bay, or Liefde Bay, for the purpose of whale fishing. To the north of Disko is an island, which deserves to be noticed, called by some navigators *Hare*, or *Hazen Island*, by others *Waygat Island*; and in the mouth of Cornelius Bay is situated another called *Unknown Island*. These places are visited by the whale fishers in the month of May. All the islands from the 71° northwards are small, and generally marked on the charts with the name *Vrowen*, or *Women Islands*. The height of the mountains decreases gradually towards the north.

Mineralogy.—The accumulation of the ice having rendered the interior of Greenland totally inaccessible, it can only be examined on different parts of the coast; and the promontory Cape Farewell, which is its most southern point, presents to the eye immense groups of precipitous mountain masses, insulated, barren and naked, sharp-pointed at the top, greatly decomposed at the surface, and cleft by the action of the snows and the ice. These rocks are intersected by narrow valleys, where immense broken and scattered masses are borne along by irresistible currents, and carried immediately to the shores, where there is no low land to intercept their course. The Granite of this island is fine granular, consisting of pearl white felspar, greyish black mica, and very little quartz of an ash grey colour. The whole rock is very much ironshot, and disintegrated. At the foot of the granite rocks occur beds of common quartz of a milk white colour, (not milk quartz,) and flesh red felspar, with small crystals of moroxite, (foliated or common apatite.) In another place are found flesh red felspar, with little quartz, common horn-blende, magnetic iron-stone, and gadolinite, crystallized in longish four-sided pyramids. A bed on the east side of this promontory, contains garnets in a fine granular greyish white rock, very much resembling the rock of Namiest in Moravia, called by Werner weiss-stein, (white stone;) but the crystals of garnet here are larger, and perfect dodecahedrons. The granite extends from Cape Farewell to the east and south-east of the coast, viz. over the islands of Staaten-huck and Kakasoeitsiak, Alluck, and Cape Discord, to a distance of more than 400 miles. Gneiss and mica slate lie upon it at Kippingajak, both rocks containing garnets. Talc slate forms a large bed in it at Akajarosanik, along with actynolite, which occurs in large masses. Near the coast of Akajarosanik, is the small island called Kakasoeitsiak. It consists of one hill, formed of a granitic rock, mixed with some horn-blende, slender crystals of zirkon, and the new mineral called *Allanite*. (See *Edin. Trans.* vol. vi. p. 371.) The rock here assumes the character of the Norwegian zirkon-syenite: but its constituent parts are of a finer grain. All the granitic mountains of the islands of Staaten-huck and Cape Farewell, are surrounded by numerous very small islands, presenting round-backed or flat conical low hills of primitive syenite. To the west of Cape Farewell, at a place called Niakornak, is a very extensive bed of yellowish white felspar, crystallized in large flat six-sided prisms, the crystals being only separated by black mica, which gives to the rock a porphyritic appearance. The place is very difficultly accessible, it being harassed perpetually by the most boisterous sea, and washed by the tide at high water. Not far from this, at an elevation of about 1000 feet, the granite is divided into immense columnar or quadrangular pieces, which, seen from a distance, present an appearance similar to the ruins of a town. The Greenlanders state, that the masses were carried thither by some giants, who inhabited the country in the oldest times, and, having been sorcerers, disappeared from the earth.

As granite is the principal rock which constitutes the mountains of this vast coast, to enumerate all the places where it is found, would exceed the limits of such an article as the present. Its most common colour is greyish white, flesh-red, and tile-red; the latter colours are characteristic of the coarse granular felspar. Magnetic iron ore is generally found either disseminated or imbedded in the red variety. In some places, molybdena occurs, and in others graphite imbedded in the rock. At Baal's river and at Disko island, iron pyrites is found; but excepting there, the rock is not very metalliferous. Precious garnet occurs very frequently; also common schorl, tourmaline, common horn-blende, jade, rock crystal, moroxite, calcareous spar, fluor spar, and the above mentioned substances. Rock crystal is only found in veins traversing the red coarse granular variety, and appears to be contemporaneous, the vein being intimately mingled with the rock, and presenting no walls. Beds of horn-blende, slate, mica slate, felspar, and quartz rest upon it; and on the red coarse granular granite at Kogneckpamiedluœk, there is an extensive bed of red ironstone mingled with massive iron-flint (eisenkiesel of Werner.) At the end of the north-eastern arm of Baal's river, in the vicinity of the great continental ice, the traveller, ascending from a narrow cliff, suddenly beholds a dreadful chaos of immense columnar granitic blocks detached from each other, and heaped together in the most fantastic groups, the planes of fracture being so fresh, that the points from which they are broken are distinctly observable. Places of desolation and devastation of this kind are very frequently met with in the mountains of Greenland. Most of the granitic rocks affect the needle.

2. The next rock, which forms numerous mountains in this country, is Gneiss. It occurs very often alternating with granite, sometimes with mica slate. Its character or texture may be ascertained partly in the cliffs and on the shores, partly by the forms of the mountains. The granitic mountains are always more decomposed, and therefore more precipitous, presenting very sharp-edged summits; the summits of the gneiss are more flat and round-backed. The texture of the gneiss is thick and thin slaty; its felspar generally pearl-grey and pearl-white, seldom flesh-red, fine granular: its mica grey, pinchbeck-brown, and blackish-brown: it contains but little ash-grey quartz. The valleys and clefts round the mountains are filled with rhomboidal fragments, many of them of immense size. The smaller fragments were used by the old Norwegians, with mica slate, hornblende-slate, and slaty claystone, to build their houses; the walls of which, although not cemented, after a lapse of several centuries, still brave the power of this destructive climate.

Gneiss constitutes one of the most elevated points of this extensive coast, viz. the mountain *Kingiktorsoak*, situated in the 62d degree of latitude. It is covered with mica slate from the shore to a height of about 1000 feet above the level of the sea, where the gneiss again becomes visible, and continues to a height of nearly 3000 feet. The top of this mountain is similar in shape to the roof of a house, where the ridge is not much elevated. It is entirely free from snow in summer, except a few small spots, where it rests in the hollows of its summit.

The mica slate resting upon the gneiss presents a variety of beds of hornblende slate, whitestone, (weiss-stein) with small garnets, talc-slate, with common and indurated talc, potstone, actynolite, and precious splintery serpentine. The gneiss is traversed with numerous veins of greenstone, varying in thickness from one inch to six feet. The greenstone which occurs in the veins resembles basalt; but it is more crystalline in its texture, lighter in its colour, and not quite so hard. Common schorl, tourmaline, and precious garnet, occur imbedded in gneiss. It contains veins of tinstone, accompanied by arsenical pyrites, wolfram, flour, and quartz, in a firth, called Arksut, situated about thirty leagues from the colony of Juliana-Hope, towards north-east. The same place is remarkable for two thin layers of cryolite resting upon gneiss; and it is the only place where this mineral has hitherto been found. One of these layers contains the snow white and greyish white variety, unmixed with any other mineral. Its thickness varies from one foot to two feet and a half, and it is divided from the underlying gneiss by a thin layer of mica, always in a state of disintegration. The other variety is of a yellowish brown colour passing into tile-red. It occurs along with iron pyrites, liver-brown sparry iron ore crystallised in rhombs, earthy cryolite, quartz, compact and foliated fluor, earthy fluor, and galena. It is remarkable, that the galena is sometimes coated with a greyish white sulphureous crust, which burns in the flame of a candle with a bluish colour, emitting a sulphureous smell.

These layers of cryolite are situated very near each other, only separated by a small ridge of gneiss, of a thickness of 27 feet: both are washed at high water by the tide, and for the most part exposed, the superincumbent gneiss having been removed. The white cryolite, seen at a distance, presents the appearance of a small layer of ice; small detached fragments have acquired, from decomposition, the shape of cubes. This mineral is called by the Greenlanders *orsuksiksæt*, from the word *orksuk*, blubber, to which it bears some resemblance. The same name is also given by the natives to white calcareous spar.

3. Mica Slate is likewise one of the most common rocks in Greenland, and an inseparable companion of gneiss: There are very few instances where they are not found in the vicinity of each other, and frequently in contact. Mica slate forms in this country a very extensive series of insulated mountains, which never rise to a considerable height, and appear generally to rest upon gneiss. Mica slate is frequently visible on the shores, and the gneiss itself forms also very extensive beds in it at Disko bay, where the whitestone also occurs in beds. The Greenlandish mica slate abounds in mica; it is generally thin-slaty, and only thick-slaty when the quartz prevails. Sometimes it has an undulating aspect; but when this is the case, it passes into primitive clay slate. The mica of this mica slate is mostly greyish-black and pinchbeck-brown, passing into brownish black, seldom silver-white. Its quartz is pearl-grey. It is sometimes mingled with nodules of pearl-grey felspar, from the size of a pea to that of an orange, and this gives it the appearance of gneiss; but they may be easily and accurately distinguished, as the mica-slate presents a surface perfectly continuous, and easily separable in the direction of the plates of the mica. The strata dip towards north-west. Mica slate also occurs in beds in various parts of this country. One of the most remarkable, most interesting, and most extensive, is that in the firth Kangerdluarsuk, in the 61st degree of latitude, in the district of Juliana-Hope. It extends about five miles in length, and four miles in breadth; its thickness varies from six to twelve feet; and it contains, besides felspar, which is its principal constituent part, hornblende, augite, actinolite, sahlite, garnet, and that new mineral which has been analysed by Dr Thomson and professor Eckeberg, called *Sodalite*. It is of pale and apple-green, leek-green, greenish white, and pearl-grey colour, partly massive, partly crystallised. Another mineral, which has not yet been analysed, occurs also with the sodalite: it is of a peach blossom red and purple-red colour. On the shore, the underlying gneiss is visible in several places. In the superincumbent mica slate, granite is found of very fine texture, partly in veins, partly imbedded. Calcareous spar and fluor occur in veins, both of which are sometimes coated with a thin crust of chalcedony, also galena in small veins. Blue phosphate of iron in detached pieces is found on the shores. The mica slate is generally decomposed and iron-shot, where the graphite is imbedded. In the firth of Arksut, a bed of very fine granular limestone is found in mica slate, which resembles the Carrara marble. The beds which occur in this rock on the mountain Kingilktorsoak have been already mentioned. Hornblende slate, forming beds in mica slate, is found in many places.

In the 64th degree of latitude, in a firth called Ameraglik, in the south of the Danish colony Godthaab, (Good-hope,) a variety of mica slate is found, which passes into talc slate, forming a very small layer in coarse granular granite. It is very remarkable, on account of the large groups of tourmaline which occur, imbedded or rather involved in talcose mica; and which are the largest crystals of this fine mineral that have been met with. At the end of the same firth, Auaitsirksarbick, in the neighbourhood of the great continental glacier, the finest garnets are found. They are of a lamellar texture, and surpass the oriental specimens in colour, lustre and hardness. At the same place, dichroite and hyperstene of a beautiful blue colour occur, along with precious garnet, in decomposed mica slate.

All the lower mountains from the 66th to the 71st degree of north latitude, and particularly all the mountains of the continent forming Disko bay, with the greatest part of the adjacent islands, are composed of mica slate. There is scarcely a square mile where the rock is entirely free from garnets. A large mountain in Omenaks firth, called Sedliarusæt, presents on its surface only the powder of mica slate, and fragments of precious garnet. From the appearance of this powder, it is probable that the rock formerly contained great masses of imbedded iron pyrites. No snow rests on the surface of this mountain in the coldest winter. The fragments of precious garnet which are found here, when clear, are the most highly prized of any on the coast. Other minerals which are found in mica-slate in Greenland, are, emery, on the island Kikertarsoeitsiak, in South Greenland; granatite, on the island Manetsok; moroxite, in very large six-sided prisms, at Sungangarsok, in North Greenland; and dichroite, in six-sided prisms, on the island Ujordlersoak, in the 76th degree of North latitude. Except iron pyrites, copper pyrites and galena, no metal occurs in this rock.

*White-stone*, (Weiss-stein,) which has lately been determined by Werner, appears to belong to this rock. It presents a white and greyish-white granular appearance, which was formerly supposed to be compact or granular felspar. It is in this country characterised by very small and minute crystals of garnet disseminated through the whole mass. Here it is found in layers of inconsiderable extent, resting on mica slate, very seldom on gneiss. It is also found in detached pieces.

4. Clay Slate is very seldom met with on this coast, and consequently the different beds which are characteristic of this rock, viz. flint-slate, lydian-stone, alum-slate, but rarely occur. Nevertheless, at the mouth of the firth Arksut, it forms two islands of some importance, called Arksut and Ujorbik. The colour of the slate is ash-grey and bluish grey; its fragments present a double cleavage, and it is traversed in all directions by numerous veins of massive and crystallized quartz, massive hornstone, and sparry iron ore of an isabella yellow colour. An extensive bed of flinty-slate and lydian-stone rests upon it on the east side of the island Ujorbik. In Ameraglikfiord, in the 65° 4′, there is a small island, where the clay-slate forms small layers in fine-grained granite, fine cubes of iron pyrites, with various truncations, occur in this slate, which is greatly decomposed. Some small islands in the south-east of Disko bay consist of clay-slate, with a variety of small beds and layers, viz. very ironshot hornblende-slate, with small garnets, whet-slate, granular hornblende and greenstone. This clay-slate may perhaps belong to the class denominated transition rocks.

5. Porphyry is very common on the south of Greenland, from Cape Farewell to the 64th degree of latitude; but it is generally found towards the interior of the continent, forming insulated rocks. In the interior of the firth Igalikko, at Akulliarascksoak, hornstone porphyry is found, very distinctly stratified, and resting upon fine-grained granite, containing large crystals of reddish white, flesh-red, and tile-red felspar, and another mineral of a talcose appearance, crystallised in six-sided prisms, and hitherto unknown. The mass of the porphyry is brownish-red, and passes in some places into clay-stone, forming claystone porphyry, the crystals then becoming less distinct. Hornstone porphyry, with a few very small crystals of felspar, occurs also in an adjacent firth called Tunugliarbik. This rock rests upon old red sand stone. The porphyry is very much decomposed. It is of a brown-red colour, and called by the natives *aukpadlrtok*, that is, blood-red rock. It contains small layers of a kind of brown-red iron ochre, which the Greenlanders use as a dyeing material, to embellish their utensils, and the interior of their houses; a species of luxury they have learned from the Europeans.

6. Syenite, and all the porphyritic rocks belonging to the primitive and transition trap-formation, are found in great abundance in this country. Hornblende is a mineral which occurs almost every where. A kind of coarse granular syenite, composed of coarse granular Labrador-felspar, and crystallized common hornblende, rests upon fine grained granite at the mountain Illejutit, or Redekammen, in the 61st degree of latitude, in the neighbourhood of that extensive bed of sodalite, sahlite, and hornblende, which has been already mentioned before. This Labrador-syenite occurs also at the mountain Kognek, in the 62d degree, upon granite of a coarser grain. In the vicinity of the mountain Kogneck, is a group of more than 50 islands, lying in a western direction, in Davis Strait, and called by the natives Kittiksut, from kitta, *west*. These islands form round-backed low hills, and consist of common felspar, of yellowish-brown and leek-green colours, and common hornblende of raven-black, and sometimes velvet-black, colour, accompanied by small four-sided prismatic crystals of zirkon of red-brown, and purple-red colour, with fine-grained common magnetic ironstone interspersed, and very little black mica. In some parts of the rock allanite occurs, of a pitch black colour. The rocks are somewhat ironshot, and disintegrated on their surface. Titanium iron ore is found in small layers, and fine granular chromate of iron. The rock itself has a striking resemblance to the zirkon-syenite, found at Friedrichswærn and other places in Norway, and described by Von Buch, Esmark, and Hausmann. The neighbouring mountains have no trace of that rock. At Narksak in the vicinity of Baal's river, brown titanite, or brunon, is found disseminated in syenite.

Granular porphyritic syenite is found at Nunarsoit, (Cape of Desolation.) Its stratification is not very distinct. It contains very extensive beds of coarse grained, tile-red felspar, and common magnetic iron-stone.

7. Primitive Trap. (*Greenstone.*) The islands which lie between the 62° and 63° of latitude present a very complete series of the rocks that belong to the primitive trap formation. The greenstone first appears at Sakkak and Ujorbik in the mouth of Arksuts-fiord, where clay-slate predominates, and extends from those islands towards the east, that is, to the continent of Greenland, alternating with greenstone of a porphyritic structure, (*porphyrartiger grunstein* of Werner,) and green porphyry. or *verde antico*. Another rock of slaty texture, consisting of compact felspar and hornblende, appears to be intermediate between hornblende slate and greenstone slate; it is here the only rock which presents very distinct stratification. The greenstone slate covers uninterruptedly both the greenstone and the green porphyry, and appears to belong to the transition greenstone formation; and perhaps the whole formation should be referred to it. It probably extends farther to the interior of the continent, as the fragments which are thrown out from the continental ice have an appearance exactly similar. Variolite is found there in small roundish rolled pieces. The greenstone, alternating with syenite, is found upon gneiss and mica slate, on the large island Nunarsoit.

8. Primitive Limestone, of fine granular texture, is

found only in beds and rolled pieces, and occurs very seldom in Greenland. Its beds are confined to gneiss and mica slate, and it is mingled with minute leaves of silver-white mica, seldom with grains of quartz. It is generally accompanied by tremolite, asbestos, actynolite, sahlite, and seldom with rock-cork. Thus situated, it occurs at the island Akudlek, at the island Manetsok, at Kakarsoit and Kaugerluluk, mountains in the vicinity of Jakobs-havn and Christians-haab, in Disko bay. It is very surprising, that no vestige of flœtz-limestone is found on this vast coast, nor does any petrifaction occur there. Very distinct impressions of the *salmo arcticus*, with its bones very little altered, occur in detached pieces on the alluvial land, which are forming daily. In the uppermost sandstone, which belongs to the brown coal of the flœtz trap formation, fragments of *pecten Islandicus* are found, which have undergone but little alteration.

The flœtz trap formation of Greenland, is perhaps the most extensive that has yet been discovered. It begins at the 69° 14′ of latitude, occupies the large island Disko, and the eastern coast of the Waygat, from Niakornak, on the northern cape of Arve-prinz island, round the Cape Noursoak, as far as the end of the southern coast of Cornelius Bay, where it reaches the great continental glacier. Hare island in the north of Disko island, Unknown island in the mouth of Cornelius bay, the islands Kakiliseit in the north of the latter, and many other northern islands, consist entirely of flœtz trap. From thence it extends over a part of the continental coast of Greenland, viz. London-coast, Svartenhuk, Ekallnit, Kangersoeitsiak, Karsorsoak, and disappears in the 76th degree under the most northern continental ice, or glacier, which precludes all further investigation.

The whole flœtz trap formation of Greenland, as far as it has been examined, rests on gneiss or on mica slate, these rocks alternating continually. The underlying primitive rocks, as well as the superincumbent flœtz trap, are always somewhat decomposed, where they come in contact. Trap-tuff generally rests immediately upon the primitive rock; it consists of balls and nodules of basalt and wacke, joined together by a cement of the same substance; the centre of the balls and nodules is very often filled with mesotype, blended with massive or crystallized apophyllite, the crystals of which are sometimes penetrated by acicular mesotype. This trap-tuff scarcely presents another mineral, and the apophyllite, or ichthyophthalmite, does not occur there in any other rock. The underlying primitive rock is very variable in its elevations, sometimes it does not surpass the level of the sea, sometimes, (for instance, at Godhavn,) it reaches a height of from 500 to 600 feet, which can be observed very exactly in the cliffs there. Columnar basalt lies upon trap-tuff; it presents four, five, and seven-sided columnar distinct concretions; the columns very seldom exceed a foot in diameter. This basalt does not include any mineral, except sometimes very minute spots of greyish white glassy felspar. Wacke generally rests upon it, forming an amygdaloid with different minerals, viz. chabasite, stilbite, analcime, chalcedony, opal, heliotrope, quartz, zeolite, miemite, and basillar arragonite. At Hare island the chalcedony is found crystallized in cubes. At Kannioak, in Omenaks-fiord, miemite occurs in kidneys, along with chalcedony, opal, wavellite, arragonite, and some quartz in grey decomposed wacke. The wacke of the flœtz trap formation of this country is generally intersected by small veins of iron-clay and bole. Lithomarge and green earth occur in nodules Olivine and augite are but seldom met with in the flœtz trap of Greenland. Laumonite, in a friable state, is found in very small veins, traversing wacke at Sergvarsoit, on the northern coast of Disko island. Most of the Greenlandish basalt affects the needle very powerfully. There are generally two, and sometimes three strata of columnar basalt, and one of them forms the summit, except at Hare island, where the summit consists of porphyry slate resting upon wacke. The shape of the mountains is very various, some of them present pyramidal, some conical forms, and some are entirely flat: Their stratification is very nearly horizontal, and the valleys between the mountains are generally narrow. There is no doubt that some of the mountains have been separated by very recent eruptions of rapid torrents.

On some parts of Disko island beds of brown coal occur in flœtz trap: they rest upon yellowish-white coarse-grained sandstone, which is very friable;—large balls of iron pyrites are imbedded in it. The beds of coal are generally divided from each other by strata of fine-grained sandstone, and are of very unequal thickness. In some places of the east coast of Disko island, in the Waygat, the sandstone becomes harder, and carbonized impressions of leaves are found in it, which are similar to those of sorbus and angelica.

The coal of Disko island is common brown coal, of slaty texture: it burns very easily, but it leaves a great residuum in the form of white ashes, which have a slaty texture, and somewhat resemble the polishing slate from Bilin in Bohemia. A very remarkable variety of brown coal, passing into bituminous wood, occurs in a small bed at Hare island. It is of slaty texture; and honey-yellow amber, in numerous grains of various sizes, is disseminated parallel to the cleavage of the coal. It rests upon ash-grey coarse-grained sandstone, is covered with grey common clay, and belongs, undoubtedly, to the newest brown coal formation. At Koome, in Omenaks-fiord, native capillary and fibrous sulphate of iron, of a beautiful green colour, is found in the cliffs of the brown coal. All the Greenland coal is subordinate to flœtz trap.

*Alluvial land* has been formed at the end of every bay and firth of the coast, and, in addition to grey and greyish-white sandy clay, it contains fragments of the neighbouring mountains. This formation is daily increasing, and contains no metallic substance, except magnetic iron sand, with which it generally abounds.

Botany.—Although Greenland affords a great variety of objects to the mineralogist, yet it offers but few to the botanist, when compared with other countries, the first efforts towards vegetation being repressed by the barrenness of the soil, and the want of the sun's genial influence. Those shrubs and trees, therefore, which in milder climates afford a comfortable shade to the wanderer, creep in this forlorn land under scattered rocks, to find shelter from their destroying enemies,—storm, snow, and ice. This land, however, presents a series of plants, which probably could not subsist in a milder climate; and in the interior of the inlets and firths may be found many species hitherto unknown in other countries. Some of the new species are published in the last number of the *Flora Danica*. There are also other spots which boast the most luxuriant verdure, but they are only places in the neighbourhood of the Greenland houses, which have been improved for many years by the blood and fat of seals and other animals. There are also small hills on the uninhabited islands, where the birds build their nests, and manuring the decomposed rocks, extort vegetation to their abode from the unfertile soil. These places, however, are but of rare occurrence, in proportion to the immense extent of the country. Innumerable cryptogamic plants, growing with great rapidity under snow and ice, supply the want of flourishing vegetation on the rocks and cliffs.

The vegetation commences very late, not till the end of May or June, in proportion to the different latitudes, and is over by the end of August or September. The bottom of the sea in these climates appears to be better suited to vegetation than the surface of the land; there is a great variety of fuci, ulvæ, and confervæ. The plants which have been hitherto found are,—

Mucor mucedo.

Zoology.—The character of the man who inhabits these latitudes, is given in a former part of the article: it will therefore only be necessary to enumerate the animals which can bear the hardships of this climate.

*Mammalia.*—There are only four different land quadrupeds, which are found in every season on the coast of Greenland, viz. the dog, the isatis, the arctic hare, and the reindeer. The arctic, or white bear, is a migrating animal: It comes from the eastern and north-eastern polar regions, in the beginning of the winter, with the floating ice, to the western coast of Greenland, and leaves it again about the end of June.

The *dog* is the faithful companion of man in this as in every other country, and would undoubtedly be so in a higher degree, if the Greenlanders treated this poor animal in a more humane manner. The dogs are in general large, and have the size and appearance of wolves. Their colour is very various, generally greyish brown, greyish white, mixed with yellow and black: they bark very seldom, but set up a dreadful howl. They sleep on the roofs of the houses of their masters, or lodge themselves in the snow, lying with only their noses out. They swim very well. The Greenlanders use them in place of horses: they harness them to their sledges, side by side, by means of thongs cut out of the *Phoca barbata*, or great seal: These thongs are ten yards long, the common distance between the dogs and the sledge; and in this manner they visit their friends in winter, or draw home the seals which they have killed over the ice of the frozen sea. They will travel sixty English miles in a day with sledges or sliders of whalebone, loaded with their two masters and five or six seals, and 100 miles if they have no load. In the most northern parts they use the dogs also in the chase of the white bear. The Greenlandish dogs are very ferocious, and often fight among themselves till one of them is killed. Canine madness is unknown in Greenland. These dogs are very prolific, having frequently nine and ten whelps twice in a year: some of the bitches eat their whelps. The Greenlanders put their dogs generally on uninhabited islands during the summer, the season in which they are useless, where these poor animals are obliged to provide for themselves, and very often perish by famine. The Greenlanders use the skins for shirts, stockings, and gloves: they make strings of the guts: they are very fond of their flesh as food, and reckon a very fat dog a great delicacy. The dog skins having a very unpleasant smell, do not form an article of trade.

The *isatis* (*canis lagopus*) generally called the arctic fox, or blue and white fox, is only found in the arctic regions, a few degrees within and without the polar circle. It inhabits the whole coast of Greenland, but lives always in the neighbourhood of the sea, in cliffs and cavities, or holes formed accidentally from fragments of rocks, and having many outlets. Their food is small birds and their eggs, eggs of sea fowls, shell-fish, and, when compelled by want, they eat grass, and all that the sea throws up. The arctic fox is of a bluish grey colour: one variety is entirely snow white, both in summer and winter. The hair is very thick, thicker in winter than in summer; and very soft and silky. The blue variety changes its colour in summer, and acquires a spotted skin of grey, blue, and white. The isatis is undoubtedly the hardiest of quadrupeds. It sets out for prey to the houses of the Greenlanders, during the severity of winter. It couples twice a year, like the dog, and, when with young, the female retires to her kennel. It swims uncommonly well from one island to another, to the distance of four and five miles, in search of prey. It is very harmless, and, when young, is very easily tamed. Its skin is highly prized, and very much thought of in China. It is generally caught by the natives in traps made of stones, like small huts, with a broad flat stone of hornblende slate, or mica slate, hanging perpendicularly by way of a door, which falls down by means of a string baited on the inside with the *salmo arcticus*, a small fish, which the isatis is very fond of. It is also taken by the European settlers in pitfalls, and in springes of iron. The flesh is not eaten by the Greenlanders, unless when they are in the greatest want of food.

The *white hare*, *arctic hare*, or *varying hare*, is in Greenland of a snow white colour, both in summer and winter, and lives in great numbers amidst the snowy mountains. It is usually fat, and feeds in summer on grass, and in winter on cryptogamic plants, particularly on lichen islandicus and nivalis (*Cetraria islandica* and *nivalis*.) Its hair is very thick and soft, but very loose. The Greenlanders are not very fond of its flesh, but they like very much to eat the raw contents of the intestines, together with the stomach. They make use of the skins, which are not an article of trade, to clothe their children.

The *rein-deer*, (*Cervus tarandus*), though very useful to the Laplanders, is only considered as an object of chase by the Greenlanders, and of no utility until deprived of life. They kill every summer more in the interior than they can carry to the shores, and their number is rapidly diminishing every year. Besides this, these thoughtless people neglect the time of their best fish and seal game for this sport. They eat the flesh, which is tender and well-tasted, raw, boiled, and dried. The hunters drink the warm blood, dressed with some berries; the contents of the stomach, called *nerrikak*, is a delicate dish. They are also very fond of the fat of the animal. The skin forms a part of their clothing, particularly of that of the women; and the inhabitant of this dreadful climate is obliged to procure a couple of fine reindeer skins during the summer, if he wishes to be agreeable to his wife. The sinews, when split, are very good threads, with which the women sew their clothes. The horns are employed for utensils and instruments. The greatest number of rein-deers is found in the vicinity of Baal's river, near to the continental ice, from the 63d to the 66th degree. They occur very seldom in more southern or more northern latitudes.

The *white bear*, *polar bear*, *or arctic bear*, (*Ursus maritimus*, or *Ursus arcticus*), is a migrating animal. It is never seen after the large or black whale (*Balæna mysticetus*) leaves the coast of West Greenland. Their size is stated by some authors to be from 13 to 23 feet, but this is probably too much exaggerated. The largest white bear which was met with on the west coast of Greenland, measured 9 feet and 4 inches from the snout to the tail, the skull of which is now in the museum of the Dublin Society. Another, caught by the celebrated navigator, Captain Phipps, (Lord Mulgrave) at Spitzbergen, measured 7 feet from the snout to the tail. The white bear seems the only animal, that, by being placed in the coldest climate, grows larger than those that live in the temperate zones. Its flesh is not so good as that of the other kinds of bear; it has an oily taste, and a fishy flavour; the liver is very unwholesome, and causes vomiting. The usual food of this animal is fish, seals, and the carcases of whales. On land, which it seldom approaches, it preys on rein-deer, hares, foxes, and birds. It lies in ambush on the flakes of the floating ice, and lurks there after seals and other marine animals; it also attacks the morse, or walrus, with which it is in constant enmity. The walrus, by reason of its large teeth, has generally the superiority, but frequently both the combatants perish in the conflict. In winter, when hungry, it sometimes attempts to break into the houses of the Greenlanders, allured by the scent of the flesh of seals, but it is very easily driven away with fire-arms and dogs. The female has only one young one, and lodges it in the snow of the floating ice, or on the shores. The affection between the parents and their young is so great, that they will sooner die than desert one another. The Greenlanders kill them with fire-arms, generally assisted by dogs; and both the man and dog feed on the flesh and fat. The skin is used for boots, and some other domestic purposes; it is also a valuable article of trade, a good skin being generally sold for three or four pounds.

The pinnated quadrupeds, or quadrupeds with fin-like feet, are, the *morse*, or *walrus*, (*Trichechus rosmarus*). It is sometimes found of the length of 18 feet, and the circumference in the thickest part is ten or twelve feet. Its weight is from 600 to 1500 pounds. It has very short legs, and five toes on each foot, joined together by webs, with a small roundish blunt nail to each. Its skin is generally an inch thick, thicker on the neck, and very much wrinkled about the joints; it is very thinly beset with grey and reddish grey hair, sometimes mouse-coloured. It has two large teeth or tusks in the upper-jaw, from a foot to two feet long, and four grinders, flat at the top, above and below, the surfaces of them generally being very much worn. It is found of the largest size in the Icy Sea. The animals feed both upon seagrass and small marine animals, viz. shells and small fishes. It sleeps upon the floating flat ice, or on the surface of the sea, and when attacked by men, will endeavour to overset the boat, or to make holes in it with their teeth; but it is very clumsy when out of the water upon the ice, where it may be killed with little difficulty. When a walrus or morse is struck with the harpoon, the Greenlanders let it run till it is wearied, and then draw in the line to kill it with the lances. The Greenlanders very seldom kill them in their small canoes; but if they do, they are always in company with three or four men. They are no more seen in large flocks on the coast of West Greenland as formerly, having been diminished by the whale fishers, who killed a great number of them. A flat island on the southern coast of Disko island, called Saitok, situated in the mouth of Disko firth, consists of alluvial land, which is covered with numberless bones and skulls of the walrus. The Greenlanders feed on their flesh, which is of a dark red colour; they use the oil in their houses, cut thongs out of the skin, and employ the tusks for their utensils and instruments.

*Trichechus manatus*, which is called *auvekæjak* by the Greenlanders, is very seldom seen on the coast, according to their own accounts; and it appears more towards Behring Straits, and the sea in the vicinity of Kamtschatka.

The *seals* may be called the flocks of the Greenlanders. They supply them with flesh, the most desirable food of this nation. The blubber furnishes them with oil for their lamps, and for their chamber and kitchen fire; the fibres of the sinews of the seal furnish thread for their clothes; of the skins of the intestines they make their windows, and their curtains for the tents; the stomach is used as a train oil vessel, and the bladder is employed for the javelins. The blood, mixed with flesh, is eaten as soup. But the most valuable thing is the skin: it covers their boats and their tents; it furnishes clothes, boots, stockings, gloves, and coverings for their bedsteads.

There are different species of seals, partly migrating, partly living on the coast of Greenland. One of the most remarkable is,

The *hooded seal*, *Klappmutze* of the Germans, *Klapmyds* of the Danes, *Neitsersoak* of the Greenlanders, *Phoca cristata* of Gmelin. It is so called from a thick folded skin on the forehead of the male, which it can draw over the eyes like a cap, to defend them against its enemies. Its hair is of a double kind, the longest silver white, the shortest black and woolly, which gives it a very beautiful appearance. It grows to the length of ten and twelve feet. The Greenlanders value the skin of the young ones very high. It is uncommonly fierce when wounded, and often attacks the canoe. These seals fight very stoutly among themselves, from jealousy, as the natives suppose. They live in flocks; are found in great numbers round Cape Farewell, and go very seldom to the northern parts of the coast. It is falsely called *Phoca leonina* by some zoologists, this being a very different animal.

The *common seal*, called *Spragled Sael* by the Danes, *Kobbe* by the Norwegians, *Meerkalb* by the Germans, and *Kassigiak* by the Greenlanders, (*Phoca vitulina* of Gmelin) is found sometimes in very large flocks on the coast of Greenland. It is one of the smaller animals of the family, but its skin is the finest of them all, and is of great value among the Greenlanders. It is principally employed for female dresses. The common seal is very cautious, and therefore caught with difficulty.

The *harp seal*, or *half-moon*, (*Phoca groenlandica*,) called *Swartside* by the Danes, *Robbe* by the Germans, and *Atarsoak* by the natives. It is nine feet long when full grown, and gives the best blubber. Its skin is of a yellowish-white and greyish-white colour, with two large black spots on the opposite sides of its body, in the form of two half-moons, the horns of which are turned in an uniform direction towards one another, and therefore called Half-moon. It becomes like the black spots in its fourth year when full grown. Its skin is the most durable, and therefore used to cover the canoes and the tents. It is incautious, and very easily taken. It never ascends the fixed ice. It is a migrating animal; comes with its young from Spitzbergen to Davis Strait about the end of March, returns in May to Spitzbergen, and comes back again in July. Three or four of them afford a barrel of blubber. It comes in great flocks, and visits the firths of Davis Strait.

The *rough seal*, (*Phoca hispida* and *Phoca fœtida*,) called *Neitsek* by the Greenlanders, is the smallest of the generally known species, very seldom exceeding four feet in length. It never frequents the high seas, but keeps always in the vicinity of the fixed ice, generally in high latitudes, and is very seldom seen southward from Disko Bay. Many thousand are killed every winter in Omenak's firth or Cornelius bay, in the 72° of latitude. The male emits an insupportable smell in its coupling time, nevertheless it is eaten with great avidity by the northern Greenlanders.

The *great seal*, (*Phoca barbata*,) called by the Greenlanders *Urksuk*, is of the largest kind, but is very seldom met with on the coast of West Greenland. It measures sometimes ten feet in length, has a thick skin, with very thin brown hairs; and on its upper lip very long white pellucid whiskers, which are curled at their points. Its flesh is white and very good. The Greenlanders cut out of the skin thongs and lines for their seal game, whips, and other domestic articles.

The Greenlanders mention some other species of seals, which very seldom occur, viz.

*Siguktok*, having a very long snout; in its body it is similar to the *Phoca groenlandica*. Perhaps it is the *Phoca ursina*.

*Imab-ukallia*, of a snow-white colour, the eye presenting a fire-red iris, probably the *Phoca leporina*.

*Atarpiak* or *atarpek*, the smallest species of seal, not exceeding the size of the hand, of a whitish colour, with a black spot of the form of a half-moon on each side of the body.

*Kongeseteriak* has, according to the description given by the natives, some resemblance to the sea-ape, which is described by Mr Heller.

The *Sea-unicorn* or *narwhal*, (*Monodon monoceros*,) called *Kernertak* by the Greenlanders, is a migrating animal. It is generally from seventeen to twenty feet long, has a smooth black skin, and a small mouth in proportion to its body. It has no teeth, but a horn, wreathed or twisted on its surface, and from eight to ten feet long, runs from the left point or end of the upper jaw. It is white, has the solidity of the hardest bone, and far surpasses ivory in all its qualities. The animal uses the horn to get at its food the sea-grass, and also as a weapon against its enemies. It has two nostrils in the skull, but they emerge in one aperture through the skin. It swims with wonderful velocity, and can only be killed when there is a great number of them together. They are always seen in flocks, in the severest winter, amidst the fissures of the fixed ice, in the bays from 70° of N. Lat. to the most northern regions. They never occur in more southern latitudes. The Greenlanders drive with their sledges to the fissures of the ice, where the animals generally come up to take air, and kill them there with their harpoons, or with guns. They eat both their flesh and skin, raw, dried, or boiled; use the blubber for their lamps; and the horns, which are highly valued as an article of trade. Most of them are killed in Disko bay, in the 70°; in Omenak's firth, or Cornelius bay, in the 72°; and at Upernavik, in the 73°.

The *white-fish*, *beluga* of the Russians, and *kelleluak* of the Greenlanders, is likewise a migrating animal, and visits the coast of West Greenland regularly every year about the end of November. It is, next to the seal, the most useful animal to the Greenlanders, and it comes at a season, when their provisions fall very short. It arrives in flocks, in very stormy weather, when the wind blows from the south-west. It has a short, roundish, very fleshy head, but the skull is longish and flat; the eyes and the mouth are small; in each jaw of each side are nine teeth; the pectoral fins are nearly of an oval form; and beneath their skin may be felt the bones of five fingers, which terminate in five very distinct projections. The body is round, oblong, and well proportioned; and its tail is divided into two lobes, which lie horizontally. Its length is from twelve to seventeen feet. In swimming it makes great use of the lobes of its tail, bending them under the body, and working it with such force as to dart along with the velocity of an arrow. One of the large size yields five barrels of good blubber. Its flesh is somewhat similar to that of beef, though oily; its skin is eaten raw, dried, and boiled. Its oil is of the best, whitest, and finest quality. The intestines are used for windows, and the curtains of tents. The sinews, when split, give the best sort of strong thread. The female white-fish has two nipples, and yields a yellowish-white milk, but it produces only a single young one, which is of a fine pearl-grey colour, but it afterwards grows white. The pearl-grey young is called *utak* by the natives. The full grown are the most beautiful animals; they are not shy, and sometimes follow, tumbling themselves round the boats. They are killed with harpoons, and also caught in large strong nets, which are set in narrow sounds between the islands.

The *porpoise*, or *Delphinus delphis*; the *nise*, or *Delphinus phocæna*; and *the sword-fish*, or *Delphinus orca*, are frequently seen on the coast, but very rarely caught.

Whales.—There are different species of whales which visit the coast of West Greenland, viz. *Balæna physalus*, or fin-fish, called *tunnolik* by the Greenlanders; *Balæna musculus*, or *northcaper*, (Green. *kepokarnak*); *Balæna rostrata*, (Green. *tigagulik*); *Balæna boops*, (Green. *keporkak*), and *Balæna mysticetus*, or the Greenland whale, called *arbek* by the natives. The *Balæna boops* or *butskopf*, comes regularly to the coast in the neighbourhood of Fredrikshaab about the end of July, when the Greenlanders, both men and women, go out in their canoes. The men in their small canoes follow the whale, and continue to throw a great number of harpoons and lances into the animal, until it dies from loss of blood. They afterwards join their canoes, fasten their spoil to them, and carry the booty to their houses, where it is divided.

The *Balæna boops* is a smaller kind of whale, its length being from twenty to twenty-five feet. It has a fin on its back, and also a protuberance which grows towards the tail. It has long rugged wrinkles under its neck, that are white inside, and greyish-black on their elevation. A great number of the shells called *Lepas balænaris*, or *Lepas diadema*, are found near its fins. Its body is longer, and sharper behind and before, than that of the other whales. Its back is of a black, and its belly of a greyish-white colour; the whalebones of this species rarely exceed the length of one foot. Its blubber is thin, and not very oily. This whale follows always along the coast farther to the north, and it is also caught by the Greenlanders in Disko Bay.

*Balæna mysticetus*, the great or Greenland whale, is the most valuable and lucrative species of this genus, on account of its bigness, and the great quantity of fat, which affords much oil; it is also the most tame, and the easiest to be caught, on account of its unwieldy size. It has no back-fin. The head of it forms one-third part of the whole body. Its eyes are very small in proportion, not much bigger than those of an ox, and black, with a white iris; they lie deep, and are placed above the junction of both lips. Instead of ears, a hole appears on each side of its head, so small that it is scarcely discernible, not admitting any thing thicker than a goose-quill; but within the flesh there is a larger orifice, formed like an ear, which enables it, as has been noticed, to hear very distinctly. The two holes, or pipes, on the top of its head, are crooked, and very similar to the holes in the belly of a violin. They are for receiving air, as well as for discharging the water which it swallows by its mouth. This is forced upwards through these holes in very large quantities, and to a considerable height, (of some fathoms) with such a noise, that it roars like a hollow wind, and may be heard at three miles distance. When wounded, it blows more fiercely than ever, the water frequently being mixed with blood. Its throat is uncommonly narrow, not exceeding the width of one inch and a half. Its tongue is eighteen feet long, when the animal measures fifty-six or sixty feet; it is then ten feet broad, is very fibrous, floats on the water, and affords four to six barrels of oil; its weight is to 600 or 800 pounds. The tongue is inclosed in long pieces of a corneous substance, generally called whalebones; and these are covered on their interior side with a kind of fibre, or straight hair of the same substance, similar to coarse horse hair. On each side of the tongue are commonly found 250 of different lengths; the longest are about the middle, and decrease towards the snout and the throat; they are attached to the upper jaw. The under jaw forms with the jaw bones an oblong triangular deep bason, of a tendinous and cartilaginous substance, which is as deep as to cover the longest whalebones in their perpendicular shape when the mouth is closed; this receptacle is, of course, deepest towards its middle part. The broad ends of the whalebones, where they are joined to the palate, are generally one foot broad; they terminate very pointed, and have the form of a curved sword; they would wound the tongue, which is very delicate, if they were not covered with hair on their inside. There are no other teeth in the mouth. This whale is very thick from the head to the middle, but thinner and sharper towards the tail; its fins and its tail stand horizontally.

In the spring of 1813, a whale was killed at Godhavn, of the length of 67 feet. The dimensions of a whale, killed in the year 1811 at Godhavn, was, from the centre of the mouth to the point of the tail, 56 feet. From the point of the under lip to the root of the fins 23½ feet. From the fins to the point between the two lobes or wings of the tail 33 feet. The length of the head was 18 feet. From the middle point of the upper lip to the blow-holes 16½ feet. The length of one of the fins 8 feet 4 inches. The thickness of a fin, on its thickest part, 1 foot 9 inches. The breadth of the tail from one extremity of its wings to the other, 22 feet 7 inches. The length of one of the blow-holes 11 inches. There were 13 ribs on each side, and in all 26 ribs. The animal was a female. The fins serve this large animal for rudders, to turn in the water, and to give a direction to the velocity impressed by the tail. The tail serves for an oar, to advance itself in the water; wherewith it swims with incredible force and celerity. When swimming a little under the surface of the water it leaves a track in the sea like a great ship, and this is called its wake, by which it often is followed. The female makes use also of the fins, when pursued, to bear the young one, placing it on its back, and supporting it by the fins on each side, from falling. They are also seen sometimes having their young upon the tail.

The skin of the whale is of a different nature. The epidermis resting upon the skin is not thicker than parchment; but when this is removed, the real skin appears, which is about an inch thick, of a bluish-black colour, fibrous and spongy; it is called by the Greenlanders *maktak*; it is very much wrinkled in the old whales, and smooth in the young ones. Beneath the skin (*maktak*) lies a yellowish white, very tenacious, reticulated fibrous substance, which affords more fritters than oil; it is called *maksak* by the natives: with this substance the real blubber is immediately connected. The blubber is of very unequal thickness, from 10 inches to one foot thick upon the back, and on the under lips two feet thick; but the latter is very cartilaginous, and intermixed with coarse nerves. The head and the back of the whale is bluish-black, the under jaw is white, and sprinkled or spotted with bluish-black, and the tail is greyish-black. The skin of the suckers is greyish-blue. The Greenlanders state, that the old animals become more and more of a greyish-white colour. The blubber of young whales is reddish-white and rose-red, that of the old is yellowish-white; the flesh of the young is dark blood-red, that of the old is dark red-brown. The bones of the whales are very porous, and afford, when sawed in pieces, the finest oil. The female whale has two breasts, with teats like a cow, and has one young one, very seldom two. When it suckles the young it lies on its side, on the surface of the sea, and the young one attaches itself to the teat. The food of the whales is the *clio arctica*, the *argonauta arctica*, *cancer pedatus*, and *cancer oculatus*, none of them exceeding the size of a common wasp. Sometimes also *oniscus pulex*, and other species of oniscus, are found in its stomach. It takes its food under water; these small insects become entangled by the hair of the whalebones, and the water is emitted partly on the sides of the mouth, partly through the blow-holes. The whale cannot remain longer than from 15 to 20 minutes under water. It sleeps on the surface of the sea, and is often caught asleep.

The settlements or colonies, which are established and supported by the Danish government on the coast of West Greenland, for the purpose of the whale-fishery, are Holsteinsburg in 67° 10′, Egedesminde and Wester-island on the southern point of Disko bay, Hunde Island, and Crown-prince-island in Disko bay, Christianshaab, Claushavn and Jacobshavn on the continent of Disko bay, Godhavn on Disko island, and Klokkerhuck on Arve-Prince-Island, situated on the entrance of the Waygat. The fishery is carried on in boats, by natives and settlers, on the account of the Danish government. The fishery was not very successful during the last ten years. The English and Scotch whale-fishers visit Disko bay every year, about the end of April, and leave it again in June. The Dutch whale-fishers, who formerly also came there every year, were prevented from fishing at all during the late war. It is only the balæna mysticetus, which is caught there at that season. It comes to the coast about the end of December, and leaves it again in June.

The spermaceti whale, or cachalot, (*Physeter macrocephalus*) the enemy of the balæna mysticetus, is seldom seen on the coast of West Greenland.

Birds.—West Greenland presents very few land birds. The largest of them is the *vultur albicilla*, the cinereous eagle, called *nektoralik* by the natives; it feeds on seals, fishes, and all kinds of birds; is of a greyish brown colour, and inhabits Greenland the whole year, sitting on the rocks with flagging wings, and flies slowly. It is eaten by the Greenlanders, and the skin employed for clothing.

The *falco rusticatus*, the *falco islandus*, and the *falco fuscus*, or Greenland falcon, called by the natives *Kirksoviarsuk kernertok*, inhabit the most remote parts of the friths; they feed on birds. The latter is of a very fine appearance. Its colour is marbled of white grey and brown. It is only eaten by the natives when compelled by hunger. All falcons inhabit Greenland the whole year.

The *beautiful snowy owl*, or *stryx nyctea*, called *orpik* by the Greenlanders, is found in the interior of the continent, in the vicinity of the glaciers. It preys on every kind of bird day and night.

The *raven*, (*Corvus corax*,) (Green. *Tulugak*,) occurs in great number, and frequents the huts of the natives, who abhor its flesh.

The *white partridge*, (*Tetrao lagopus*), called in North Greenland *ageiksek*, and in South Greenland, *kauio*, inhabits in summer the mountains for the sake of crowberries, (*Empetrum nigrum*). In winter it descends to the valleys near the shores. It is brownish in summer, and changes its colour in winter into a snow white. The Greenlanders like very much to eat its intestines raw.

Of small land birds, which all leave this country in the beginning of winter, are only seen the *fringilla lapponica*, (Green. *Narksamiutak*), the *fringilla linaria*, (Green. *Orpingmiutak*), the *motacilla oenanthe*, (Green. *Kussektak*), and the *emberiza nivalis*, (Green. *Kopanauarsuk*). The arrival of the latter about the end of May announces the approach of spring. In autumn, in the beginning of September, it collects again in great flocks, in order to migrate.

Of water birds, there occur on the coast,—

1. *Anas bernicla*, bernacle. Green. *Nerdlek*.
2. *Anas clangula*, golden-eye. Green. *Kærtlutorpiarsuk*.
3. *Anas histrionica*, harlequin. Green. *Tornaviarsuk*.
4. *Anas boschas*, mallard. Green. *Kertluctok*.
5. *Anas glacialis seu hyemalis*, long tailed duck. Green. *Aglek*.
6. *Anas spectabilis*, king-duck. Green. *Siorakitsok*.
7. *Anas mollissima*, eider-duck. Green. *Mitek*.

The *Anas molissima*, or eider-duck, visits the coast as soon as the grass begins to grow, and plucks the finest down from its breast to form its nest. The down taken from the nest is the finest and most elastic. It is customary to take away the first eggs, which occasions a second laying, and a second deplumation. They lay their eggs on uninhabited islands among the grass growing near the shores. They brave the severest winter of the arctic regions, and their breeding-places are the most northern. They come constantly every spring to the same spot again, if not disturbed. The Greenlanders kill them with darts and guns, watching their course (when they dive) by the air-bubbles, and strike them when they ascend. The flesh is valued as food. The skin of this duck is the most valuable of all as a garment placed next to the skin. The down forms a very considerable article of trade. The colony Egedesminde produced in the year 1808, 1000 pounds weight of that article. One pound sterling is paid for one pound weight of the best sort of down.

Of *Merganseres* occur,—1. *Mergus serrator*. Green. *Paik*.

2. *Mergus merganser*, goosander. Green. *Pararsuk*.

Of *Auks*.—1. *Alca impennis*, great auk. Green. *Isarokitsok*.

2. *Alca torda*, razor-bill. Green. *Akpardluk*.
3. *Alca pica*, black-billed auk. Green, *Akpa*.
4. *Alca arctica*, puffin. Green. *Killangak*.
5. *Alca alle*, little auk. Green. *Akpalliarsuk*.

The *alca pica* vies with the eider duck in point of utility to the Greenlanders. The skins are used for clothing, and the flesh is eaten. They only approach the coast when the cold becomes very severe, and breed in summer in the clefts of the remotest rocks. They are killed in canoes with darts, and give food to the Greenlanders in the months of February and March, when they want every other supply from the sea. It appears that the words *alca*, *auk*, and *akpa*, are formed from the note or sound which the bird emits when flying or swimming in large flocks.

Of *Petrels*, or *Procellariæ*, are seen,—

1. The *Procellaria glacialis* fulmar. Green. *Kakordluk*; and,
2. The *Procellaria puffinus*, shear-water. Green. *Kakordlungoak*.

The prey of these birds being the blubber of the whale, they are only found in the vicinity of the whale-fisheries. They are, from the nature of their food, extremely fetid; and so stupid and voracious, as to be killed with rods in their attempt to obtain prey. They are rarely eaten.

Of *Guillemots*.—1. *Colymbus Grylle*, black guillemot. Greek. *Sergvak*.

2. *Colymbus glacialis*, northern guillemot. Green. *Tudlik*.

3. *Colymbus septentrionalis*, red-throated guillemot. Green. *Karkfak*.

Their skins are very excellent for clothing, in consequence of their durability.

Of *Terns*.—*Sterna hirundo*, great tern. Green. *Imerkoteilak*.

Their eggs are the most delicate of all water-birds. They come latest in summer, that is, in the beginning of June, and leave the coast earliest, that is, in the beginning of September, under great noise.

Of *Gulls*.—1. *Larus marinus*, black-backed gull. Green. *Nayardluk*.

2. *Larus trydactylus*, kittiwake. Green. *Tattarak*.

3. *Larus candidus*, ivory gull. Green. *Nayauarsuk*.

4. *Larus arcticus*, *cataracta parasitica*, arctic gull. Green. *Meriarsairsok*.

5. *Larus glaucus*, glaucous gull. Green. *Naya*.

Of *Pelicans*.—1. *Pelicanus carbo*, corvorant. Green. *Okaitsok*.

2. *Pelicanus cristatus*, crested corvorant. Green. *Tingmik*.

3. *Pelicanus bassanus*, gannet. Green. *Kuksuk*.

All these birds are used as food; their skins for clothing.

Of *Scolopax*.—1. *Scolopax gallinago*, common snipe. Green. *Sigrektok*.

2. *Scolopax jardreka*, jardreka. Green. *Sargvarsursoak*.

Of *Tringa*.—1. *Tringa striata*, striated sandpiper. Green. *Sirksariarsungoak*.

2. *Tringa interpres*, Hebridal sandpiper. Green. *Telligvak*.

3. *Tringa lobata*. Green. *Nelloumirsortok*.

4. *Tringa fulicaria*. Green. *Kajok*.

5. *Tringa alpina*, dunlin. Green. *Tojuk*.

Of *Charadrius*, or *plover*—1. *Charadrius apricarius*, alvargrim. Green. *Najoirovek*.

2. *Charadrius stiaticula*, ringed plover. Green. *Tukagvajok*.

Fishes.—Greenland cannot boast of valuable fisheries. The natives attend only to their seal-game, and neglect entirely every other branch of industry. The few Europeans residing there are occupied with trade. There can be no doubt, however, that such an extensive coast would afford numerous and profitable banks. Some have already been discovered at Tunugliarbik, Guannersoak, Fredericksbaab, Fishfiord, Sukkertop, Amertlok, where *different species of cod-fish* are caught; for instance, *Gadus æglefinus*, (Green. *Misokarnak*;) *gadus callarias*, (Green. *Sarolik*;) *gadus morrhua*, (Green. *Saraudlirsoak*;) and *gadus barbatus*, (Green. *Ogak*.) In the north of Greenland, in the 70, 72, and 73d degrees, were discovered very extensive *flounder banks*. The *pleuronectes hippoglossus*, holibut, Green. *Netarnak*, sometimes of a weight of more than 100 pounds, is found in abundance in the neighbourhood of the colonies of Godthaab and Sukkertop. Extensive banks of the *pleuronectes cynoglossus*, (Green. *Kaleraglick*,) were lately discovered at Jacobs havn in Disko bay, and at Omenak in Cornelius bay. Different species of *salmo*, viz. the *salmo carpio*, (Green. *Ekalluk*,) the *salmo alpinus*, (Green. *Iviksarsok*,) and the *salmo rivalis*, visit every year the friths and inlets of the continent. But the most remarkable of all the fishes is the *salmo arcticus*, called *Angmarsæt*, the Greenlanders deriving their daily food from them. It forms their bread, and makes also a sort of dessert after their most delicate repasts. The *Angmarsæt* live at sea most part of the year; but, at the end of May, they come in immense numbers into the bays and friths. They are taken in nets in all kinds of vessels, and even with the hands, in great multitudes. The whole bottom of the sea seems covered with them. They are dried on the rocks, put into sacks, and preserved for the winter under heaps of stones. They are generally eaten dried instead of bread, but many are dressed fresh as soon as they are taken. They seldom exceed seven inches in length. They have a very strong sharp smell when they are dry; and are, on the whole coast of Norway, in bad credit, as a very noxious fish, a calumny which they do not deserve. The impression of this fish occurs frequently in an indurated gray sandy marl on the end of the bays. Next to *angmarsæt*, the Greenlanders eat most of the *ulkes*, a kind of *cottus*, particularly *cottus scorpius*. They eat the fishes dried, or boiled in sea water, but the heads of *pleuronectes* are eaten putrid.

Insects.—The Greenlanders are tormented with very troublesome insects. The *culex pipiens*, a kind of musquitoes, appear in the months of June, July, and August in myriads. But a great number of other insects increase, from the incredible filthiness of the natives.

The insects, which contribute to the comforts of life, are, *Cancer phalangium*, a species, which has some resemblance to *cancer longimanus*, the cancer *squilla*, and cancer *homaroides*. The minute species of *Cancer pedatus*, and *Cancer oculatus*, afford food to the whale, and their existence is therefore of great importance to the natives. Numerous species of *oniscus* are found partly in the sea, and partly attached to the bodies of several marine animals.

Vermes.—Numerous species of *gordius* and *lumbricus* are found, and the intestines of the arctic quadrupeds, birds, and fishes, swarm with different species of *ascarides*. Of the interesting family of *Nereis* occur ten species.

Shells.—The coast of Greenland cannot boast of numerous varieties of beautiful shells, of which the seas of the warm climates abound. Of *Asterias* occur the *asterias rubens*, with 6 rays; the *spongiosa*, with 5 conical rays; the *papposa*, with 12 and 13 rays; the *minuta*, with 6 rays, and the *ophiura*, with 5 rays. In Discofiord is found the *asterias caput medusæ*. Of *Echinus* exists only the *saxatilis*; 12 species of *Serpula*; 3 species of *Chiton*, one of which is new, and not yet described; its testæ are marbled of a yellow and red colour. Of *Lepas* occurs on the shores, *lepas balanus*, and *balanoides*; and on the skin of the Balæna bonps, the *lepas balænarus*, or *diadema*.

Of Bivalvia are found the *mya* arenaria, arctica, truncata and byssifera, the latter a new species; only one *Cardium*, viz. ciliare; three *Veneres*, the islandica, minuta, and fragilis. The *pecten* islandicus. The *mytilus* edulis, discors and faba. The myæ and mytili are eaten by the natives, and the shells used as spoons.

Univalvia are: some *patellæ*, *argonauta*, *arctica*, the favourite food of the balæna mysticetus; the *helix* pellucida, nitida, and haliotoides; the *trochus* cinerarius, divaricatus and helycinus; the *tritonium* undatum, despectum, antiquum, glaciale, lapillus, fornicatum, clathratum, craticulatum, and ciliatum; the two latter are new species. Of *Nerita*, the littorea only is found.

In the friths and inlets are found various *tubiporæ*, *madreporæ*, *milleporæ*, and *celleporæ*, but all very minute. *Flustræ* and *sertulariæ* grow on the whole coast in great numbers; *alcyonia* and *spongia* occur very seldom.

It will no doubt be interesting to our readers to have a catalogue of works concerning Greenland, which have been published at different times.

The oldest accounts of Greenland will be found in *Kongs-speilet*, or *Speculum regale*. More in Whitfeldt's *Chronica*, and in Lychsander's *Chronike*. Copenhagen, 1602. Part of it is translated into English, and published in Purchas' *Pilgrims*.

Jens Munks *Navigatio Septentrionalis*, in Danish, was published at Copenhagen, 1624, 8vo. It contains his voyage for discovering a north-western passage, and some account of Greenland.

Isaac de la Pereyre wrote a *Relation de la Groenlande*. Paris, 1643, 8vo. It was translated into the Danish and German language.

From this time to the year 1721, some curious critical pamphlets were written concerning East and West Greenland, viz.

Rudolph Cappel, *Orbis Arcticus*. Hamburgi, 1675, 4to.

Arngrimi Jonæ, *Groenlandia*, (in Latin.) Hafniæ, 1688. 8vo.

Thormodi Torfæi, *Historia Vinlandiæ Antiquæ*. Havniæ, 1705, 8vo.

Thormodi Torfæi *Groenlandia antiqua*. Havniæ, 1706, 8vo. and 1708, 8vo. *cum tabulis geographicis*.

Pierre de Mesange, *les aventures et les voyages de Groenlandt, avec une relation de l'origine, de l'histoire, des mœurs, et du paradis des habitants du pole arctique*, à Amsterdam, 1720, 2 vols. 8vo.

Zorgdrager *oud en nieuwe Groenlandish Walvischery*, 4to. Amst. translated into German, Hamb. 1724, 4to.

Hans Egede, the celebrated Danish missionary, went to Greenland in the year 1721, and published, in the year 1729, at Copenhagen, in 4to. *Den gamle Groenlands nye perlustration*. It was soon translated into English, German, Dutch, and French.

Afterwards he published, in the year 1738, at Copenhagen, in 4to, *Omstandelig og udforlig Relation angoende den Gronlandske Missions Begyndelse og Fortsættelse*, (containing his journal.)

Paul Egede, his son, the second Danish missionary, published soon afterwards, continuation of *Relationerne betreffende den Gronlandske Missions Tilstand* from 1734 to 1740.

In the year 1788 he published his last work, *Efterretningerne om Groenland, uddragne af en Journal holden fra Aarene*, 1721 till 1788. Copenhagen, 8vo. with plates.

Nils Egede, his brother, who was a merchant in Greenland, published a continuation of *De Gronlandske Relationer*, from 1739—1743.

In the year 1761, David Crantz, of the German Unitas Fratum, visited their settlements on the coast of West Greenland, and remained there till August, 1762. In the year 1765 he published, *Historie von Groenland*. 2 Bande, 8vo. with plates. Barby; and in the year 1770, Fortsezzung (continuation) *Der Historie von Groenland*. His account was translated into English, Dutch, and Swedish.

The Rev. Otto Fabricius, who was a missionary in Greenland during five years, published his *Fauna Groenlandica* at Copenhagen, in 1780, in 8vo.

The first Greenlandish Grammar was published by Paul Egede in the Danish and Latin language at Copenhagen, in 1760, in 8vo.

The first dictionary in Greenlandish, Danish, and Latin, was published by Paul Egede, in 1750, in 8vo.

Both works were very much improved by Otto Fabricius, the Grammar in 1791, and in a second edition in 1801, and the Dictionary in the year 1804, 8vo.

Paul Egede was also the first who translated the New Testament into the Greenlandish language. It was reprinted in the year 1803, and very much improved by Otto Fabricius.

Besides this, partly by the Danish Society for the furtherance of the missions, partly by the Unitas Fratrum, psalm-books, prayer-books, and other religious books, have been printed, and distributed gratis amongst the Greenlanders.

GREENLAW, is a small town of Scotland in Berwickshire, and is situated on a plain, watered by the Blackadder, nearly in the centre of the county. There are here the remains of two religious houses, which were dependent on the priory of Kelso. Marchmont house, the seat of the family of Marchmont, is about two miles from the town. Greenlaw is the county town of Berwickshire. Its population is about 600.

GREENOCK, is a sea-port town in Scotland, situated on the Frith of Clyde, about 22 miles below Glasgow, and 46 above Ayr. It contains many neat and well built houses, but its streets are irregular and narrow; and its general appearance is far from being elegant. Of late years, it has extended very much to the west, and there, as might have been expected from the opulence and taste of the inhabitants, a great improvement has taken place, both in the general plan and in the structure of individual edifices. The principal public buildings of Greenock consist of the infirmary, which was erected in the year 1808 at an expence of nearly 2400*l*. and contains good accommodation for a considerable number of patients; the theatre, erected the same year, at an expence of 2500*l*.; a bridewell, erected in 1809, at an expence of 1340*l*.; and a tontine inn, erected in 1802, at at expence of 10,000*l*. There are three established churches, viz. the West Church, which serves the country part of the parish, is very old, and very uncomfortable; the New Church, built in 1762, a large commodious place of worship in the centre of the town, and having a steeple attached to it 146 feet high; and the East Church, originally built in 1774 as a chapel of ease, but erected into a parish church in 1809. There is also a Chapel of Ease for the Gaelic population, built in 1791, at an expence of 1700*l*. and containing 1600 people. Besides these, there are various dissenting meetings: the Burgher meeting, erected in 1791, at an expence of 1300*l*. and containing 1000 sitters; the Antiburgher, erected in 1803, at an expence of 1122*l*.; the Relief, erected in 1808, at an expence of 2,200*l*., and containing 1700 sitters. There is also a Tabernacle, a Methodist meeting, and a Roman Catholic chapel. A Unitarian preacher in the theatre on Sunday evenings. There are public schools for all the various branches of literature and science. A free school, established in 1790, is under excellent management, and gives useful and religious education to hundreds of poor boys and girls, at an expence of 6*s*. 8*d*. per annum for each child. In 1812, a society was instituted in Greenock and Port Glasgow for the encouragement of arts and sciences. About 150 subscribers, at 5*s*. each per annum, were obtained, and the whole funds are distributed in prizes to persons of genius and merit. For some years, there has been connected with this an exhibition of paintings. Since 1793, there has existed an institution, under the title of the Greenock and Innerkip Farmer and Agricultural Society. There are several subscription and circulating libraries, with extensive collections of books. One newspaper, the Greenock Advertiser, is published thrice a week. The poor, who are very numerous, are supported partly by the public collections, partly by voluntary assessments, and partly by the interest of sums, which from time to time have been bequeathed to them by the charitable. There are various societies established by particular trades and professions, whose principal object is to afford relief to their decayed members: Such as the Ship-carpenters Society, instituted in 1732; Master Wrights Society, instituted in 1754; Shoemakers Society, instituted in 1754; Journeymen Coopers Society, instituted in 1792; Widows Society, instituted in 1796, &c. The Merchants House Society was instituted in 1787; five guineas are paid on admission, and 5*s*. annually for the support of those families or individuals belonging to it, who have grown indigent. There was formerly in Greenock a society, designed the Clyde Marine Society; but in 1786 it was incorporated by act of parliament with the Glasgow Marine Society. This institution is very rich and very useful. There are several banks and branches of banks established at Greenock, which do a great deal of business.

The old harbour of Greenock, begun to be built in 1707, contains about 10 acres. These are inclosed within two circular quays, in the middle of which is another quay built in 1712, projecting like a tongue. The original cost was 10,000 merks Scots, or 5625*l*. sterling, which was to be defrayed by a malt duty, and was liquidated in 1740, leaving a surplus of 1500*l*. In 1801 and 1803, acts of parliament were obtained for enlarging and improving the harbour; and when all the plans are executed, the accommodation for shipping, &c. in this port will be of a very complete and superior kind. The new harbour will contain about 8 acres of ground, which were obtained from Sir John Shaw Stuart and Lord Cathcart at 5 guineas per fall, and a shilling per fall of feu duty. During the last ten years, 85,000*l*. have been expended in extending the harbours, by building new quays, sheds, &c. and an additional sum of 25,000*l*. will be required to finish the work, including the expence of building a new graving dock.

The expence of erecting the present sheds, and keeping them in repair, has cost the trustees of the harbour 9868*l*. and those yet to be erected will not cost less than 3132*l*., making together 13,000*l*.

The revenue received from them for the year ending
September 1812, was 1201*l*.
Do. 1813, 1472
Do. 1814, 2052
Do. 1815, 2053

And the yearly rent on an average for five years ending in April last, is 1609*l*.

The anchorage or ring money for the year ending
September 1813, was 175*l*. 13
Do. 1814, 181 17
Do. 1815, 218 12

making the yearly rent on an average for three years 192*l*.

Ship-building is not so much followed as might have been expected at such a port as that of Greenock. On an average, there are about 10 or 12 vessels built annually. As to quality and construction, these vessels are equal to any in the united kingdom. There is a graving dock, which was erected by share holders in 1783. The building yard of Messrs John Scott & Co. containing a graving dock, a basin, boat and mast sheds, blacksmith's shop, &c. is, in point of size and convenience, superior to any private establishment of this kind in the kingdom. Mr Steele also has excellent premises for building and repairing ships.

There are four large rope works, and several smaller ones. They employ from 200 to 300 hands, and manufacture annually about 1000 tons of cordage, which is sold for the use of the shipping of the port, and for exportation to the colonies. There is one rope-work for making patent cordage. Sailcloth is also manufactured here to a considerable extent. There are two manufactories for this article. Greenock contains two soap and candle manufactories, which are carried on to a large extent, principally for supplying our North American and West India colonies with these articles. One of them is an old establishment, having existed since the year 1772. There are also two extensive breweries, both of which export large quantities, solid and in bottles. While the French West India islands were in our possession, the supply of this article was very great, particularly light coloured table beer. There are two iron and brass founderies; one large hat manufactory, and several smaller ones; a green glass and a flint glass work; three tan works; a pottery; and a lamp-black manufactory. All these depend greatly on the export trade, and the demand for the shipping.

An account of the number of ships and vessels, with their tonnage, and number of men and boys usually employed, registered, and belonging to the port of Greenock for the years ending 30th Sept. 1814 and 1815:

| | Ships. | Tons. | Men. |
|---|---|---|---|
| Year ending 30th Sept. 1814, | 360 | 34,159 | 3325 |
| Do. 30th Sept. 1815, | 336 | 35,210 | 3220 |

At present there are 379 ships, brigs, sloops, &c. registered at the custom-house, admeasuring 47,268 tons, and navigated by 3457 men.

An account of the number and tonnage of ships and vessels, which were of, and belonging to, the port of Greenock, with their number of men, that have traded to and from foreign parts, or coastwise, or been employed in fishing, in the years ending 5th January 1815 and 1816, accounting each vessel but once in the year.

The herring fishery has been long an object of importance to the town of Greenock. So far back as the year 1688, it was carried on to a considerable extent. Since that period, it has experienced frequent vicissitudes. The following statement will shew its present situation:

In the year ending the 5th of April 1815, there cleared out for the herring fishery 177 vessels, 6896 tons, manned with 958 men. Carried out 688,171 square yards of netting, 68,205½ bushels of British salt, and 36,861½ barrels.

Entered inwards from do. 174 vessels, 6612½ tons. Carried in 24,503½ bushels salt, 11,394½ barrels (not filled) with herrings, and 23,603½ barrels of herrings.

Exported to Ireland, 5828 barrels; to the north of Europe 350; to the West Indies 24,203. Total exported 30,381 barrels.

In the year ending the 5th of April 1816, there cleared out for the fishery 149 vessels, 5623 tons, manned with 814 men. Carried out 547,167 square yards of netting, 53,434½ bushels of salt, 30,172 barrels.

Entered inwards from the fishery 157 vessels, 5975 tons. Carried in 15,382 bushels salt, 6941 empty barrels, and 24,275½ barrels of herrings.

Herrings exported to Ireland, 4478 barrels; to the north of Europe 859; and to the West Indies 23,368. Total exported 28,705 barrels.

An account of the amount of duties received at the port of Greenock, for the two years ending 5th January 1815 and 1816.

| | | |
|---|---|---|
| Year ending | 5th January 1815, | L.376,713 15 10½ |
| Do. | 5th January 1816, | 403,176 6 8 |

Account of the amount of drawbacks and bounties paid forthe same period.

| | | Drawbacks. | Bounties. |
|---|---|---|---|
| Year ending | Jan. 5. 1815, | L.41,120 5 7¼ | L.67.978 8 3¾ |
| Do. | Jan. 5. 1816, | 32,924 2 3¾ | 81,617 19 1¾ |

The excise duties and drawbacks are not included in the above.

The total receipt of the duties of customs at the port of Greenock, year ending 5th January 1816, was 403,176*l.* 6*s.* 8*d.* principally under the following heads:

| | |
|---|---|
| Upon general goods imported | L.115,717 13 11¾ |
| Upon sugar, rum, coffee, tobacco, wine, &c. for home consumption . . . . . . . . . . | 275,111 10 2¼ |
| And upon general goods exported | 12,347 2 6 |
| | 403,176 6 8 |

And there was paid during said year for bounties, on linen, sail cloth, silk, sugar, and cordage, exported, 81,617*l.* 19*s.* 2¼*d.*

Vessels entered and cleared at the custom-house 1815, and paid harbour dues in and out.

| | Harbour Dues |

Making an average per year for three years of 247*l.* 5*s.* 10*d.*

In 1757, the population of Greenock was 3900. In 1781, it was 12,000. In 1792, it was 14,299. In 1797, it was 15,000. In 1802, it was 17,458, the number of houses being 1029; of males 8194, and of females 9262. In 1804, it was 20 000. And in 1811, it was, exclusive of those at sea, 19,042, having increased in the preceding 20 years 4743, or 1212 males, and 3531 females. Greenock is a burgh of barony. It was erected in 1757, by Sir John Shaw Stuart the superior, and is governed by a council of 9 feuers, 2 of whom are annually elected to the office of bailies, with corresponding powers. In 1795, the rental of the parish, comprising 5065 Scots acres, was 3500*l.* sterling, its valued rent being 2285*l.* Scots. In 1810, the rental was 10,000 sterling. (*r*)

GREENWICH, is a market town of England, in the hundred of Blackheath, and county of Kent. It is delightfully situated on the south bank of the Thames, where the river is from 320 to 360 yards broad at low water, and is principally celebrated for its splendid naval hospital, and for the Royal Observatory. The kings of England had a royal residence at Greenwich since the reign of Edward I. A. D. 1300. After the restoration of Charles I. when the buildings had fallen almost into ruin, this monarch ordered them to be taken down, and a magnificent palace of freestone to be erected on the spot, from the designs of Webb, the son-in-law of Inigo Jones. Only one wing of this edifice was completed, at the expence of 36,000*l.* Charles occasionally resided in it; but it was not till the reign of William III. that any farther progress was made in the building. The government having resolved, on the suggestion of the queen, to provide an asylum for old and disabled seamen, Sir Christopher Wren recommended that the unfinished palace should be devoted to this purpose. A grant of the palace and adjoining lands was made in 1699 to commissioners. The foundation stone was laid on the 3d June 1696, and was gradually enlarged and improved till it reached its present state of splendour and magnificence.

The following account of Greenwich hospital has been abridged from a very full and excellent description of it in the *Beauties of England and Wales.*

Greenwich hospital is principally built with Portland stone, and consists of four distinct quadrangular masses of buildings, distinguished by the names of the respective sovereigns, in whose reigns they were founded or built. The grand front opens on a terrace, skirting the southern bank of the Thames, and extends 865 feet in length, in the centre of which is a descent to the river, by a double flight of steps. The ground plan of the whole edifice forms nearly a square, of which King Charles's building occupies the north-west angle; Queen Anne's, the north-east; King William's, the south-west; and Queen Mary's, the south-east. The interval between the two former buildings forms a square 270 feet wide, in the middle of which is a statue of George II. sculptured by Rysbrach, out of a single block of white marble, which weighed 11 tons, and was taken from the French by Admiral Rooke: this statue was given to the hospital by Sir John Jennings, who was governor from 1720 to 1744. The inscriptions on the pedestal were by Mr Haugan. The space between the two latter buildings, which include the hall and chapel, with their elegant domes, and the two colonnades, forms a lesser square. The two squares are intersected by a spacious avenue, leading from the town through the hospital. The buildings which immediately front the Thames have a general correspondence in style and arrangement. The north and south fronts of each exhibit the appearance of a double pavilion, conjoined above by the continuation of an Attic order, with a balustrade, which surmounts the whole, but is separated below by an open portal. The centre of each pavilion displays an elegant pediment, supported by four Corinthian columns, and the sides a double pilaster of the same order. King Charles's building contains the apartments of the governor and lieutenant-governor, the council-room, and anti-chamber; with 14 wards, wherein 300 pensioners may be accommodated. In the council-room are several portraits: in the anti-chamber two large sea-pieces, given to the hospital by Philip Harman, Esq.; and a series of six small pieces, representing the loss of the Luxemburgh galley, in 1727. Queen Anne's building, which was erected between 1698 and 1728, contains several apartments for inferior officers, with 24 wards for 437 pensioners. King William's building stands to the south-west of the great square, and comprises the great hall, vestibule, and dome, designed and erected by Sir Christopher Wren, between the years 1698 and 1703. To the inner side of each range is attached a colonnade 347 feet in length, supported by Doric columns, and pilasters 20 feet in height. The great hall, or saloon, is 106 feet in length, 56 in width, and 50 high: the ceiling and sides are covered with portraits and emblematical figures, executed by Sir James Thornhill, for which he was paid at the rate of 3*l.* per square yard for the ceiling, and 1*l.* for the sides, amounting in the whole to 6685*l.* The west front of King William's building, which is of brick, was finished about 1725 by Sir John Vanbrugh: the building contains 11 wards, wherein are 551 beds. The foundation of the eastern colonnade, which is similar to that on the west side, was laid in 1699; but the chapel, and the other parts of Qeen Mary's building which adjoin to it, were not finished till 1752. It corresponds with King William's, and is furnished with 1092 beds, in 13 wards. The chapel which forms part of Queen Mary's building, is one of the most elegant specimens of Grecian architecture in this kingdom, and was erected from the classical designs of the late James Stuart, Esq. It is 111 feet in length, and 52 in width, and is capable of accommodating 1000 pensioners, nurses, and boys, exclusive of the seats for the directors and other officers. The entrance portal consists of an architrave, frieze, and cornice, of statuary marble: the folding-doors are of mahogany, highly enriched by carving. The interior is finished in an elegant style, and is adorned with many appropriate paintings, the most distinguished of which is the altar-piece, executed by West, and representing the preservation of St Paul on the island of Melita. There is a double range of windows on each side of the chapel. Without the walls of the hospital stands the infirmary, erected in 1763, after a design by Stuart: it forms an oblong quadrangle, 198 feet long and 175 broad, consists of two stories, and is divided into two principal parts, appropriated respectively to those whose cases require surgical aid, and to those who need only medical assistance. It contains sixty-four rooms, and each is fitted up for the accommodation of four patients. It also includes a chapel, hall, kitchen, and apartments for the physician, surgeon, and apothecary; with hot and cold baths, and other necessary offices. Near the hospital is the school, where 200 poor children are educated. The school-house was erected in 1783, by Stuart. It is 146 feet long, 42 broad, exclusive of a Tuscan colonnade, in front 180 feet long, and 20 broad, for the boys to play in during bad weather. The pensioners, who are the objects of this noble charity, must be seamen disabled by age, or maimed either in the king's service, or in the merchant service, if the wounds were received in defending or taking any ship, or in fight against a pirate. Foreigners, who have served two years in the British navy, become entitled to the benefits of this institution in the same manner as natives. The widows of seamen are provided for, having the exclusive privilege of being nurses in the hospital. The number of pensioners is upwards of 2400, (of whom at an average 203 die annually,) who are furnished with clothes, diet, and lodging, with a small allowance of pocket-money. The nurses are 144, each of whom receives eight pounds per annum as wages, with every necessary of life. The commissioners of the hospital are about 100, and consist of all the great officers of state, the archbishops, the lord chancellor, the judges, the master and five senior brethren of Trinity-house, the lord mayor, and three senior aldermen of London, with some of the principal officers of the hospital. The annual average expence of each pensioner, according to the report of the commissioners of naval enquiry, was estimated at 27*l.* 10*s.* 9*d.* per man; and of the nurses 29*l.* 15*s.* each, the total annual expence being 69,206*l.* 5*s.* The funds of the establishment are principally derived from a duty of sixpence per month, paid by every mariner, either in the king's or merchant's service; the forfeited estates of the Earl of Derwentwater, containing many valuable lead and other mines; various benefactions from different sovereigns, from parliament, and from private persons, from fines for offences committed on the Thames, from the half-pay of such of its officers as have regular salaries, and from other sources of less importance.

Greenwich park, which is vested in the crown, was encircled with a wall by James I. and contains 188 acres. It is planted chiefly with elms and Spanish chesnuts, some of which are of a very large size. In one part of the park are the remains of many ancient barrows, in some of which were found human bones, spear heads, &c. The upper part of the park is considerably elevated above the Thames; and on one of the eminences stands the Royal Observatory, which was built by Charles II. in 1675, on the site of the ancient tower erected by Duke Humphrey in the reign of Henry VI. It is built of brick, and is by no means an elegant structure; but it contains excellent apartments for the Astronomer Royal, and commodious rooms for the admirable instruments, with which it is now furnished. Flamstead, the first Astronomer Royal, died in December 1719, and was succeeded by Dr Halley. Dr Bradley succeeded upon the death of Halley in 1742, and died in 1762. Dr Bliss held the office for two years, and was succeeded in 1764 by Dr Maskeline. Mr Pond, the present Astronomer Royal, succeeded Dr Maskelyne in 1811, and, by means of the fine mural circle constructed by Troughton, has already made a series of the most valuable observations, decidedly the most accurate that have been made in any of the other observatories of Europe.

A farther account of the institution, and of the instruments it contains, will be found in our history of ASTRONOMY, and in the articles CIRCLE and OBSERVATORY.

The church of Greenwich is an elegant stone building, and was erected in 1718. Greenwich contains two hospitals for poor people, and several schools for the education of the poor, and some excellent boarding schools. The following is the population abstract for 1811, for the town of Greenwich:

| | |
|---|---|
| Number of houses | 2,315 |
| Number of families | 3,276 |
| Ditto employed in agriculture | 96 |
| Ditto in trade and manufactures | 1,002 |
| Males | 8,723 |
| Females | 8,224 |
| Total population | 16,947 |

GREGORIAN CALENDAR. See CHRONOLOGY.

GREGORIAN TELESCOPE. See OPTICS.

GREGORY, St VINCENT. See GEOMETRY.

GREGORY, JAMES, an eminent Scotch mathematician and natural philosopher, was born at Aberdeen in the month of November 1638. He was a son of the Rev. Mr John Gregory of Drumoak, in Aberdeenshire,* who was married to the daughter of Mr David Anderson of Finshaugh, the brother of Alexander Anderson, who was professor of mathematics at Paris: (See ANDERSON.) Having lost his father in the 13th year of his age, the charge of his education devolved upon his elder brother David Gregory, who put into his hand the Elements of Euclid, and stimulated the ardour which he had begun to show for mathematical learning. After having completed his philosophical studies at the Marischal College of Aberdeen, James Gregory directed his particular attention to the subject of optics, and he published the results of his labours in a work, entitled *Optica promota seu abdita radiorum reflexorum et refractorum mysteria, geometrice enucleata, cui subnectitur Appendix subtilissimorum astronomiæ problematum resolutionem exhibens*, Lond. 1663. It was dedicated to Charles II. and was completed with the assistance and encouragement of his brother David, after he had been stopped a long time at the twenty-sixth problem.† This work is remarkable, as containing the description of a new reflecting telescope, and the deduction of the true law of refraction. The method in which he has investigated this law is remarkable for its elegance and originality; and, in his experimental demonstration of it, we are furnished with a striking proof of the accuracy of his observations. In comparing the refractions calculated by the law with the experiments of Vitellio on the refractions of water and glass, the greatest error amounts to 61′ in water, and 94′ in refractions from glass into water. When compared with the experiments of Athanasius Kircher, the greatest error in water is 89′, in wine 110′, in oil 104′, and in glass 93′; but in comparing them with his own observations, the greatest error is only 15′; and it is remarkable that he made the index of refraction for water 1.3347, differing only 0.0018 from 1.3358 the most accurate measure, whereas Vitellio made it 1.306. Before the publication of the *Optica Promota*, Gregory was informed, that he was anticipated in the discovery of the law of refraction by Descartes, and he thus alludes to it in his preface:—*Et ex analogiis in prima hujus tractatuli propositione declaratis, inveni primam hujus opticæ partem, de genuina refractionum hypothesi et mensura nescius scilicet* (*propter inopiam novorum librorum Mathematicorum in alias inclyta Bibliotheca Abredonensi*) *hæc eadem a Cartesio fuisse inventa.*

The invention of the reflecting telescope formed an epoch in optics and astronomy. Gregory was not acquainted with the errors in dioptric instruments, arising from the unequal

* The following quotations, relative to the Rev. John Gregory of Drumoak, are taken from Spalding's *History of the Troubles in Scotland*, from 1624 to 1645:

"Upon the second day of June, 1640, Mr John Gregory, minister at Drumoak, was brought into Monro by a party of soldiers: He was taken out of his bed naked upon the night, and his house pitifully plundered. He was closely keeped in Skipper Anderson's house, having five musketeers watching him night and day, and sustained upon his own expences. No not his own wife could have private conference with him, so strictly was he there watched. At last he is fined to pay Major-General Monro 1100 merks, for his outstanding against the covenant, and syne got liberty to go; but in the General Assembly holden in July, he was nevertheless simplicieter deprived, because he would not subscribe the covenant; and when all was done, he is forced to come in and yield to subscribe the covenant.

"Next, Mr John Gregory having been summoned to appear before the General Assembly (1640), by and attour his being fined in 1000 merks, as ye have before, was deposed from the ministry of Drumoak. The Laird of Drum deals for him, being his own pastor, and upon swearing and subscribing the covenant, and teaching penitentially, with great difficulty he was again restored (1641) to his own parish-kirk.

"Upon Thursday, the 15th of April, 1641, being a presbytery day, Mr John Gregory, of whom ye heard before, teached a penitential sermon in New Aberdeen. It was not found satisfactory by Mr James Hervie, Moderator, and the remnant members of the Presbytery, and he was ordained to put the same in write. The brethren advised the same with the next Provincial Assembly, who found it not satisfactory, and therefore they ordained him to preach penitentially at certain kirks, till he gave content to the next ensuing General Assembly; which he obeyed. He was received and reinstated in his kirk (1641).

"Upon Tuesday, the 6th of September, 1642, Mr John Gregory, at the visitation of the kirk of New Aberdeen, teached most learnedly upon the fourth verse of the second chapter of the Colossians, and reprehended the order of our kirk, and new brought in points. Mr Andrew Cant, sitting beside the reader, as his use was, offended at this doctrine, quickly closed the reader's book, and laid down the glass before it was run, thinking the minister should the sooner make an end; but he beheld and preached half an hour longer than the time. Sermon being ended, the brethren conveen to their visitation, where Mr Andrew Cant impugned this doctrine, desiring the said Mr John to put the same in write. He answered, he would not only write, but print his preaching, if need so required, and abide by all that he had teached as orthodox doctrine. The brethren heard all, and had their own opinions, but without any more censure they dissolved, somewhat perturbed with Cant's curiosity.

"Upon Thursday he railed out in his sermon against the said Mr. John Gregory's doctrine, and on Sunday likewise. At last, by mediation of the town's baillies, at a cup of wine, they two were agreed, and settled, with small credit to Cant's business."

Mr Gregory of Drumoak was one of the first persons in Scotland who understood the use of the barometer as an instrument for predicting the weather. Having one day observed that the mercury was falling rapidly, he advised his parishioners to remove the sheaves of corn from the low grounds on the banks of the river Dee. They immediately followed his advice, and when they found his prediction verified by an unusual rise of the river, they were naturally led to regard him as a being of a superior order. Mr Gregory died about the year 1652.

† "Ubi diu hæsi omni spe progrediendi orbatus; sed continuis hortatibus et auxiliis fratris mei Davidis Gregorii in mathematicis non parum versati (cui siquid in hisce scientiis prestitero, me illud debere non inficias ibo) animatus tandem incidi in seriam imaginis considerationem, &c." *Pref. ad Optic. Promot.*

refrangibility of the rays of light; and his principal object in proposing this new instrument, was to avoid the error arising from the spherical figure of the lenses. It consisted of a parabolic concave mirror, near whose focus is placed a small concave elliptic speculum, having a common focus with the parabolic one. This instrument gave rise to the Newtonian telescope, in which the small mirror is plane, and reflects the image to the side of the tube where the eye-glass is placed; and also to the Cassegrainian telescope, which differs only from that of Gregory in having the small speculum convex instead of concave. The Gregorian principle has been almost universally used for telescopes of a moderate size. The Newtonian form has been adopted in the magnificent instruments used by Dr Herschel; but it is extremely probable, that the Cassegrainian telescope, in which the rays never cross each other at a focus,* will hereafter be considered as the most valuable of the reflecting telescopes. The *Optica Promota* is terminated by a collection of astronomical problems. The object of one of these, is to determine the paralaxes of two planets from their conjunction; and, in a scholium to this problem, he points out the great use of the transits of Venus and Mercury, in determining the sun's parallax.† This happy idea, which has since been of such service to astronomy, has always been ascribed to Dr Halley.

Mr Gregory went to London about the year 1664 or 1665, and was introduced to Mr Collins, the secretary to the Royal Society, who introduced him to some of the best practical opticians, for the purpose of having his reflecting telescope executed. A Mr Rives was employed for this purpose, but he could not polish the speculum upon the tool, and was therefore obliged to do it with a cloth and putty. The success of this trial was so little, that Gregory was discouraged from making any farther attempts, and a tube was never even made to hold the mirrors. He afterwards, however, made some trials with a little concave and convex speculum; but, to use his own words, "they wer but rude, seeing I had but transient views of the object; being so possessed with the fancie of the defective figure, that I wold not be at the pains to fix every thing in its due distance."

After these unsuccessful attempts to construct a reflecting telescope, Gregory left England, and fixed his residence at Padua, which was then in high repute as a seat of mathematical learning. Here he published, in 1667, 1668, his work, entitled, *Vera Circuli et Hyperbolæ Quadratura in propria sua proportionis specie inventa, et demonstrata*, which contains his discovery of an infinitely converging series for the areas of the circle, ellypsis, and hyperbola. A copy of this work was laid before the Royal Society by his friend Mr Collins, and was honoured with the approbation of Lord Brouncker and Mr Wallis. In the following year he reprinted it at Venice, and added a new work, entitled, *Geometricæ pars universalis quantitatum curvarum transmutationi et mensuræ, inserviens*, which contains a new method for the transmutation of curves. This work had previously appeared at Padua in 1668; and, upon its arrival in England, was read by Mr Collins to the Royal Society.

In the year 1670, Mr Gregory received, in a letter from Mr Collins, a series for the area of the zone of a circle, and being informed that Newton had invented an universal method by which he could square all curves geometrical and mechanical by infinite series of that kind, Gregory applied himself to the investigation of the subject, and discovered an universal method of series, which he communicated to Newton, and the other English mathematicians, by a letter to Collins, dated February 1671. His brother David urged him to publish this method without delay; but he declined this from the most honourable motives; for Newton having been the first inventor, he thought himself bound to wait till his method should be published.

Upon Mr Gregory's return to London, we believe in 1668, he was elected a fellow of the Royal Society, and laid before them an account of a dispute in Italy relative to the earth's motion, which Riccioli and his followers had denied. About this time also he engaged in a dispute with the celebrated Huygens through the medium of the *Philosophical Transactions*. Huygens published in the *Journal des Sçavans*, July 2d 1668, some animadversions on Gregory's quadrature of the circle, and particularly objected to the proposition which stated the impossibility of expressing perfectly the area of a circle in any known algebraical form besides that of an infinite converging series. Gregory defended himself in the 37th Number of the *Philosophical Transactions*, and the dispute was carried on with considerable warmth by both parties. The whole of the controversy will be found in Huygens' *Opera Varia*, vol. ii. p. 463.

In 1668, Gregory published in London his *Exercitationes Geometricæ*, a small work of twenty-six pages, which contains the following subjects:

Appendicula ad verum Circuli et Hyperbolæ Quadraturam.

N. Mercatoris Quadratura Hyperbolæ Geometrice demonstrata.

Analogia inter Lineam Meridianam Planispherii Nautici et Tangentes Artificiales Geometrice demonstrata; seu quod secantium Naturalium additio efficiat Tangentes Artificiales.

Item, Quod Tangentium Naturalium additio efficit Secantes Artificiales.

Quadratura Conchoidis.

Quadratura Cissoidis.

Methodus Facilis et Accurata componendi Secantes et Tangentes Artificiales.

The preface to this work, and the introduction to the *Appendicula*, &c. are remarkably interesting, in so far as they throw considerable light on the dispositions of our author. He speaks with great severity of the jealousy and injustice of his contemporaries, and alludes to the treatment which he had received from Huygens. In the introduction to the *Appendicula*, he resumes this subject with more keenness. He declares, that Huygens had accused him of ignorance and plagiarism; and after arguing against Huygens' claim to the discovery, he concludes with this remarkable passage: "At parum refert quis sit ejus primus inventor, satis enim constat me primum esse publicatorem; neque mihi esset difficile affirmare (si modo mentiri vellem) me ante 20 annos illam cognovisse: utcunque sit, conabor hic circuli et hyperbolæ quadraturam ad talem per-

* The effect of the collision of the rays in the focus was first noticed by Dr Brewster, in the most perfect achromatic telescopes: (See *Treatise on New Philosophical Instruments*, p. 44. and 193.) It was afterwards observed in reflecting telescopes by Mr Kater, who has examined the subject with much attention and success: (see *Phil. Trans.* 1813, 1814.) We have found from experiment, that the heat of a burning lens, as well as the light, is more intense within than without the focus, and that radiant heat is also most intense within the focus. Mr Leslie had long before obtained the same result with regard to radiant heat. It is therefore certain, that this diminution of effect must arise from the collision of the luminous as well as of the calorific rays. We may therefore lay it down as a principle in the construction of optical instruments, that the rays should, if possible, never be brought to a positive focus.

† "Hoc Problema pulcherrimum habet usum, sed forsan laboriosum in observationibus Veneris vel Mercurii particulam solis obscurantis: ex talibus enim solis parallaxis investigari poterit." *Optic. Promot.* schol. prop. 87.

fectionem promovere, ut Hugenius prolem suam vix cognoscat."

Mr Gregory was about this time elected professor of mathematics in the university of St Andrew's. In 1669, he married the daughter of George Jamieson, the celebrated Scottish painter, by whom he had a son, James, the father of Dr John Gregory, (the subject of a succeeding article,) and two daughters. In August 1672, he began a correspondence with his friend Mr Collins, relative to the comparative merits of his own telescope, and that of Sir Isaac Newton. The sentiments of the two philosophers were communicated to each other by their respective friends, and the dispute was thus carried on in the most amicable manner. The correspondence has been published by Dr Desaguliers, at the end of his edition of Dr David Gregory's Catoptrics and Dioptrics.

In the year 1669, a work was published at Rotterdam, by Mr George Sinclair, professor of philosophy in the university of Glasgow, entitled *Ars Nova et Magna Gravitatis et Levitatis;* and another work on hydrostatics, by the same author, appeared at Edinburgh in 1672. Mr Sinclair had been dismissed from his professorship soon after the restoration, on account of his political principles, and had given offence to the Royal Society of London, by charging them with negligence and injustice. He appears also to have acted improperly towards one of Mr Gregory's colleagues, and thus to have incurred the displeasure of that mathematician. In the year 1672, Gregory, under the assumed name of Patrick Mathers, archbedal to the university of St Andrew's, attacked Sinclair, in a tract, entitled *The great and new art of weighing Vanity, or a discovery of the Ignorance and Arrogance of the great and new Artist, in his Pseudo-philosophical writings.* To this work is annexed *Tentamina de motu penduli et projectorum.*

In 1674, Gregory was called to the mathematical chair in the university of Edinburgh, a situation which he did not live long to enjoy. In the month of October 1675, when he was walking home from supper, he was struck suddenly blind, and expired a few days afterwards, in the 36th year of his age.

The following is a list of the inventions and discoveries of James Gregory, as given by Dr Hutton. The reflecting telescope; burning mirror;* quadrature of the circle, ellipse, and hyperbola; method for the transmutation of curves; geometrical demonstration of Lord Brouncker's series for squaring the hyperbola; demonstration that the meridian line is analogous to a scale of logarithmic tangents, of the half complements of the latitude; a simple converging series for making logarithms; solution of the famous Keplerian problem, by an infinite series; method of drawing tangents to curves geometrically, without previous calculation; a rule for the direct and inverse method of tangents, depending on the principle of exhaustions; a series for the length of the arc of a circle from the tangent, and *vice versa*, and also for the secant and logarithmic tangent and secant, and *vice versa*; and serieses for the length of the elliptic and hyperbolic curves. See Hutton's *Mathematical Dictionary*, 2d edition, p. 601, &c. and the other works quoted in the article.

GREGORY, David, Dr, a celebrated astronomer and mathematician, was the nephew of the subject of the preceding article, and the eldest son of David Gregory of Kinnairdie. He was born at Aberdeen in the year 1661, and after receiving his education at the grammar school of that town, he went to Edinburgh for the purpose of completing his studies. In 1684, when he was only 23 years of age, he was appointed professor of mathematics in the university of Edinburgh, and in the same year he published his work, entitled *Exercitatio Geometrica de Dimensione Figurarum sive specimen methodi generalis Dimetiendi quasvis figuras.* Mr Gregory having found among his uncle's papers particular examples of infinite series, without any of the methods, proposes in this treatise to explain a method which may suit the examples given by his uncle; and he does this by applying the principles of indivisibles, and the arithmetic of infinites, to particular cases in hyperbolas, parabolas, ellipses, spirals, cycloids, conchoids, and cissoids. He also explains several methods of reducing compound quantities into infinite series, so that the method of infinites may be conveniently applied to them.

Dr Gregory seems to have been one of the earliest supporters of the Newtonian philosophy in Britain; and while the doctrines of Descartes were in the highest esteem at Cambridge, the true system of the universe was publicly taught in the university of Edinburgh.

In consequence of a report that Dr Bernard proposed to resign the Savilian professorship of astronomy at Oxford, Gregory went to London in 1691, and, in spite of the brilliant talents of his competitor Dr Halley, he was appointed to succeed Dr Bernard, through the friendship and influence of Sir Isaac Newton and Mr Flamstead. Halley, who lost this appointment in consequence of his attachment to infidelity, became afterwards the colleague of Dr Gregory, when, in 1703, he succeeded to Dr Wallis as Savilian professor of geometry. During Mr Gregory's residence in London, he was elected a fellow of the Royal Society, and before his appointment to the mathematical chair, the university of Oxford had conferred upon him the degree of doctor of physic.

In the year 1692, Viviani, one of the disciples of Galileo, had proposed to mathematicians the Florentine problem of the quadrable dome. Leibnitz and Bernoulli had resolved this problem on the very day on which they had received it, and the Marquis L'Hospital had also given a solution. Dr Wallis and Dr Gregory were equally successful, and the latter published his solution in the *Philosophical Transactions* for 1693, under the title of *Solution of the Florentine Problem, concerning the Testudo veliformis Quadrabilis.* In 1694, he published another paper in the *Transactions*, containing a vindication of his uncle from a charge preferred by the Abbot Galloise,* that James Gregory and Dr Barrow had stolen from Roberval their general propositions concerning the transformation of curves. Galloise replied in the *Memoirs of the Academy* for 1713; and Dr Gregory put an end to the controversy by a very sharp answer, which appeared in the *Philosophical Transactions* for 1716, and which was the last of his communications to that learned body.

In 1695, Mr Gregory published at Oxford his *Catoptricæ et Dioptricæ Sphericæ Elementa*, a work which formed the substance of lectures which he delivered in 1684, in the university of Edinburgh, and which require no higher mathematical knowledge than the Elements of Euclid. This work was republished and translated by Dr William Browne, with several important additions; and a third edition of it by Dr Desaguliers, appeared in 1735. In this work it is stated, that, in the construction of telescopes, "it would perhaps be of service to make the object lens of a different medium, as we see done in the fabric of the eye, where the crystalline humour (whose powers of refracting the rays of light differs very little from that of glass) is by nature, who never does any thing in vain, joined with the aqueous and vitreous humours, (not differing from water as to their power of refraction,) in order that

* See our article Burning Instruments.

† See *Hist. Acad. Par.* 1693.

the image may be painted as distinct as possible on the bottom of the eye. We cannot agree with the biographers of Dr Gregory, in considering this suggestion as any thing like an anticipation of the principle of the achromatic telescope; for it was impossible to form an idea of the construction of that instrument, till it was discovered that bodies possess different dispersive powers. This remarkable property of light, even the penetrating mind of Newton failed to discover; and we must not allow ourselves to diminish the well-earned reputation of Dollond, by giving to another any portion of the praise which is so exclusively due to himself. In the year 1747, more than 50 years after this conjecture of Dr David Gregory was published, the celebrated Euler suggested the human eye as the model of an achromatic telescope, and several ignorant foreigners have ventured to claim a share of Dollond's merit for this illustrious mathematician. Whatever credit therefore may be given to Euler, must now be claimed for our countryman David Gregory.

In the year 1697, our author published, in the *Phil. Transactions*, a long paper *On the properties of the catenaria or curve line, formed by a heavy and flexible chain, hanging freely from two points of suspension.* The leading properties contained in this communication, had been previously discovered and published by Huygens, Leibnitz, and Bernoulli, but without demonstrations; and Mr Gregory proposed to himself to demonstrate these properties. An anonymous writer in the Leipsic Acts for February 1691, attacked this paper as destitute of originality. Dr Gregory replied to this attack in the *Phil. Trans.* for 1699, and claimed as his own discovery the property of the catenaria as being the true geometrical figure of an equilibrated arch. This discovery, however, had been previously made by Dr Hooke *.

The greatest of Dr Gregory's works, and that on which his fame must rest, appeared at Oxford in 1702, entitled *Astronomiæ Physicæ et Geometriæ Elementa*, Fol. In this valuable work, all the physical explanations are founded on the principles of the Newtonian philosophy; and the geometrical parts are either proved by reference to the writings of standard authors, or demonstrated by lemmas inserted in their proper places. A very admirable analysis of this work was given, apparently by Dr Halley, in the *Phil. Trans.* for 1703. Newton himself considered these elements as an excellent defence and exposition of his philosophy.

This work was followed, in 1703, with an edition of Euclid, entitled *Euclidis quæ supersunt omnia, Gr. et Lat. ex recensione Davidis Gregorii*, M. D. &c. It was published in prosecution of a plan of Sir Henry Saville to print the works of the ancient mathematicians. It contains the Elements; the Data; two musical tracts; the Optics and Catoptrics; the tract *De Divisionibus;* and a fragment, *De Levi et Ponderoso.*

In the year 1704, Dr Gregory published, in the *Philosophical Transactions*, a paper on *Cassini's Orbit of the Planets*, in which he shewed that the hypothetical curve proposed by that astronomer, is not consistent with the received doctrines of astronomy.

After Dr Halley had been appointed to the Savilian professorship of Geometry in 1703, he embarked with Dr Gregory in the prosecution of Sir Henry Saville's plan, and had begun the publication of the Conics of Apollonius; but after having proceeded a short way in this undertaking, he was seized with an illness of which he died, at Maidenhead in Berkshire, on the 10th of October 1710, in the 49th year of his age.

He left behind him four sons by his wife Elizabeth, daughter of Mr Oliphant of Langtown, to whom he was married in 1695. Among his manuscripts were found, *A Short Treatise of the nature and Arithmetic of Logarithms*, which was afterwards published in Dr Keill's translation of Commandine's Euclid; a *Treatise of Practical Geometry*, which was translated and published by Mr Maclaurin in 1745; and a commentary on the *Principia*, which Newton kept by him many years after the author's death. Sir Isaac had entrusted Gregory with a manuscript copy of the *Principia* for this purpose, and he availed himself of the annotations of his friend in the second edition of that immortal work. A complete copy of these observations was presented, by the present Dr James Gregory, to the library of the University of Edinburgh, where it is carefully preserved. There are some paragraphs in this manuscript in the handwriting of Huygens, concerning his theory of light.

His wife, who survived him, erected an elegant monument to his memory in the church of St Mary, Oxford, with the following inscription:—

P. M.
DAVIDIS GREGORII, M. D.
Qui Aberdoniæ natus, Jun. 24, 1661,
In Academia Edinburgensi
Matheseos prælector publicus,
Deinde Oxonii
Astronomiæ Professor Savillianus,
Obiit Oct. 10. A. D. 1710;
Ætatem illi heu brevem Natura concessit,
Sibi ipsi longam prorogavit
Scriptor illustris.
Desideratissimo viro
Elizabetha Uxor.

David Gregory, of Kinnairdie, the brother of the celebrated James Gregory, was born in 1627, and served an apprenticeship to a mercantile house in Holland; but having a great passion for knowledge, he returned to Scotland in 1655, when he was 28 years old, and having succeeded to the estate of Kinnairdie, by the death of an elder brother, he devoted his time to mathematics and philosophy. He appears to have been the first person in the country who had a barometer, and he had the honour of corresponding, upon meteorological subjects, with the celebrated Mariotte. "About the beginning of the last century," says Dr Reid, "he removed with his family to Aberdeen, and, in the time of Queen Anne's war, employed his thoughts upon an improvement in artillery, in order to make the shot of great guns destructive to the enemy, and executed a model of the engine he had conceived. After making some experiments with this model which satisfied him, the old gentleman was so sanguine in the hope of being useful to the allies in the war against France, that he set about preparing a field equipage with a view to make a campaign in Flanders, and in the mean time sent his model to his son, the Savilian Professor, that he might have his and Sir Isaac Newton's opinion of it. His son shewed it to Newton, without letting him know that his own father was the inventor. Sir Isaac was much displeased with it, saying, that if it tended as much to the preservation of mankind as to their destruction, the inventor would have deserved a great reward; but as it was contrived solely for destruction, and would soon be known by the enemy, he rather deserved to be punished, and urged the professor very strongly to destroy it, and if possible to suppress the invention. It is probable the professor followed this ad-

* See Robison's *System of Mechanical Philosophy*, Vol. I.

vice; for at his death, which happened soon after, the model was not to be found.

When the rebellion broke out in 1715, the old gentleman went over a second time to Holland, and returned when it was over to Aberdeen, where he died, about 1720, in the 93d year of his age. He left behind him a historical manuscript of the transactions of his own time and country."

Mr Gregory had twenty-nine children by two wives, and he had the good fortune to see three of his sons professors of mathematics at the same time, viz. David Gregory at Oxford, James at Edinburgh, and Charles at St Andrews. James was first a professor of philosophy at St Andrews, and succeeded David when he removed to Oxford. Charles was created professor of mathematics at St Andrews in 1707, and in 1739 he resigned that office in favour of his son, Professor David Gregory, who died in 1763, and left behind him a good compendium of arithmetic and algebra, with the title, *Arithmeticæ et Algebræ compendium, in usum Juventutis Academicæ*, Edin. 1736. His son David was master of an East India ship. David Gregory, the eldest son of the Savilian professor, was appointed Regius Professor of Modern History, at Oxford, and died in 1767, after having filled, for many years, the situation of dean of Christ's church. The celebrated James Gregory, the inventor of the reflecting telescope, had only one son, James, born in 1674, who was professor of medicine in King's College, Aberdeen. His youngest son was Dr John Gregory (the subject of the next article), and the father of the present Dr James Gregory, professor of the practice of medicine in the university of Edinburgh.

GREGORY, John, Dr, an eminent physician, was born at Aberdeen on the 3d of June 1724, and was the youngest child of Dr James Gregory, professor of medicine in King's College, Aberdeen, by his second wife, Anne Chalmers, the only daughter of the Rev. Principal Chalmers of King's College.

In consequence of the death of his father when he was only seven years old, the charge of his education devolved upon Principal Chalmers, his elder brother Dr James Gregory, who had succeeded his father as professor of medicine, and his cousin, the late celebrated Dr Reid. After receiving the first rudiments of his education at the grammar school of Aberdeen, he entered King's College, and made rapid progress in the knowledge of ethics, mathematics, and natural philosophy.

In 1742, he went to Edinburgh, accompanied by his mother; and having resolved to pursue the study of medicine, he attended the different medical lectures, and became a member of the Medical Society, at a time when his friend, the celebrated Dr Akenside, was a member of the same institution. In the year 1745, Mr Gregory went to Leyden, to complete his professional studies, under the care of Albinus, Gaubius, and Van Royen, who were at that time the ornaments of the university. Here he became acquainted with the famous John Wilkes and the Hon. Charles Townshend, two of the greatest wits of the age; and before he left this university, he received from King's College, Aberdeen, an unsolicited degree of doctor of medicine. Upon his return from Holland, he was chosen professor of philosophy in the same college; and during the years 1747, 1748, and 1749, he read lectures in mathematics, experimental philosophy, and moral philosophy.

Having resolved, however, to establish himself as a physician at Aberdeen, he resigned his professorship in the end of 1749, and went for a few months to the continent.

After he returned to Scotland, he married, in 1752, Elizabeth, daughter of William Lord Forbes, who brought him a handsome addition to his fortune. This accomplished and amiable woman, who possessed the rare combination of great beauty and great intelligence, lived only nine years after her marriage, and left her husband and six children to lament their premature loss.

Perceiving little prospect of succeeding in Aberdeen to the full extent of his wishes, Dr Gregory resolved to settle in London, where he arrived in 1754. He was chosen a Fellow of the Royal Society in the same year; and, from the influence and attachment of his friends, as well as from his own professional talents, he had the best prospects of an extensive practice. The death of his elder brother, however, occasioned a vacancy in the professorship of physic in King's College, Aberdeen; and being solicited to accept of this situation, he returned to his native country in 1756, and began to discharge the duties of his new office.

Among the eminent young men who at that time adorned the university, were Reid, Campbell, Beattie, Gerard, John Stewart, professor of mathematics in Marischal College, and David Skene, a correspondent of the celebrated Linnæus. These young men established a literary society or club, which met weekly at a tavern. A short essay was read by each member in rotation, and a literary or philosophical question was proposed every night as a subject of discussion at the following meeting. The proposer of the question was obliged not only to open the discussion, but to digest the opinions of the different members in the form of an essay, which was ingrossed in the album of the society. Several of those composed by Dr Gregory, on philosophical, moral, and political questions, still exist, and contain some of his favourite opinions. Some of the separate essays which Dr Gregory contributed were afterwards corrected and published in 1765, under the title of *A Comparative View of the State and Faculties of Man with those of the Animal World*. It was considerably enlarged by the author in a second edition, and has passed through other editions since his death.

About the end of the year 1764, Dr Gregory removed from Aberdeen to Edinburgh. In 1766, he was appointed professor of the practice of physic, on the resignation of Dr Rutherford; and in the same year, he succeeded Dr Whytt as first physician to his Majesty for Scotland. His lectures on the practice of physic were delivered in the years 1767, 1768, and 1769; but, in consequence of an arrangement with Dr Cullen, professor of the theory of physic, these celebrated individuals gave alternate courses of the theory and practice of medicine. The lectures of Dr Gregory were never committed to writing. Having made himself fully master of his subject by previous meditation, he required no other aid than a few notes, containing the heads of his lecture. The introductory lectures, however, were carefully composed, and related principally to the duties and qualifications of a physician. Many copies of these lectures having been taken by his pupils, one of them was offered for sale to a bookseller. It therefore became necessary to anticipate this fraudulent design, by the publication of a correct copy, which appeared in 1770, and afterwards in a more enlarged and perfect form, in 1772. In the same year, Dr Gregory published *Elements of the Practice of Physic, for the use of Students*, a work intended as a text-book for the use of his pupils. He proposed to embrace all the diseases of which he treated in his lectures; but he did not live to bring the work farther down than to the end of the class of febrile diseases.

After the death of his wife in 1761, Dr Gregory occupied his solitary hours in the composition of a *Father's Legacy to his Daughters*. This admirable work, which every mother should study, and every daughter read, was written under the impression of an early death. It is marked by a deep knowledge of the world and of human character, and abounds with the finest lessons of piety and virtue.

From the eighteenth year of his age, Dr. Gregory had been, at irregular intervals, attacked with the gout; a disease which he inherited from his mother, who died suddenly, in 1770, while sitting at table. Dr Gregory anticipated a similar event for himself, and often mentioned this impression to his friends. In January 1773, when conversing with his son, the present Dr Gregory, the latter remarked, that having had no attack for the three preceding years, he might expect a pretty severe fit of it that season. His father was displeased with the prediction, which was unfortunately too correct; for he was found dead on the morning of the 10th of February, although he had gone to bed in his usual health.

"Dr Gregory," says his friend and biographer, Mr Tytler, "was in person considerably above the middle size. His frame of body was constructed with symmetry, but not with elegance. His limbs were not active; he stooped somewhat in his gait; and his countenance, from a fulness of feature, and a heaviness of eye, gave no external indication of superior powers of mind or abilities. It was otherwise when engaged in conversation. His features then became animated, and his eye most expressive. He had a warmth of tone and of gesture, which gave a pleasing interest to every thing which he uttered. But, united with this animation, there was in him a gentleness and simplicity of manner, which, with little attention to the exterior and regulated forms of politeness, was more engaging than the most finished address. His conversation flowed with ease; and when in company with literary men, without affecting a display of knowledge, he was liberal of the stores of his mind.

"He possessed a large share of the social and benevolent affections, and which, in the exercise of his profession, manifested themselves in many nameless, but important, attentions to those under his care; attentions which, proceeding in him from an extended principle of humanity, were not squared to the circumstances or rank of the patient, but ever bestowed most liberally where they were most requisite. In the care of his pupils, he was not satisfied with a faithful discharge of his public duties. To many of these, strangers in the country, and far removed from all who had a natural interest in their concerns, it was a matter of no small importance to enjoy the acquaintance and countenance of one so universally respected and esteemed."

Dr. Gregory left behind him three sons and two daughters, the eldest of whom is Doctor James Gregory, professor of the practice of medicine in the university of Edinburgh, who fully inherits the virtues and talents of his ancestors. The works of Dr John Gregory were published at Edinburgh in 1788, in 4 vols duodecimo, and were enriched with a well written life of the author, by the late Mr Tytler, Lord Woodhouselee, to which we have been indebted for the preceding facts.

GRENADA, the most southerly of the Caribbee islands in the West Indies, is situated between 12° 20′ and 11° 58′ North Lat. and between 61° 20′ and 61° 35′ West Long. It is twenty leagues north-west of Tobago, and the same distance from the nearest point of the American continent. It is about twenty-five miles in length from north to south, and fifteen at its greatest breadth, contracting gradually towards both extremities. A chain of mountains traverse the whole island from north to south, and give rise to a great number of small rivers; and in the highest ground is a circular lake called Grand Etang, from which several of these streams derive their source. There is a bay on the north-west coast (which has been recently fortified at great expence,) so capacious and secure, that sixty men of war may ride in it safely almost without casting anchor. The air is salubrious, and the soil fruitful in the productions of the climate.

Grenada was discovered by Columbus in 1498, and was at that time inhabited by a warlike people called Charaibes or Caribbees. The Spaniards do not appear to have made any attempt to form a settlement on the coast, and the natives remained free and undisturbed till the year 1650. At this period, the French governor of Martinico, Du Parquet, landed on the island with 200 adventurers, who seem to have been resolved upon a wanton destruction of the unoffending inhabitants, and an unwarrantable possession of the country; but being hospitably received by the unsuspecting objects of his unjustifiable attack, they pretended to make a purchase of the island for a few knives and hatchets, a quantity of glass beads, and a barrel of brandy to the chief. Immediately assuming the sovereignty, and having roused the natives to resistance by their tyrannical proceedings, they took measures to extirpate the whole race as lawless rebels. This they are said to have speedily accomplished by a course of atrocious massacres; and a few wretched survivors of their butcheries having thrown themselves headlong from a steep rock, rather than fall into the hands of such merciless enemies, the French settlers, with characteristic levity, gave to the spot the name of *Le Morne des Sauteur*, the Hill of the Leapers. The perpetrators of these enormities soon began to quarrel among themselves, and to suffer, in their turn, the oppressions of tyrannical governors. By a succession of calamities and revolutions, the narration of which would interest few readers, the prosperity of the settlement was so much impaired, that, in the year 1700, more than twenty years after the sovereignty had been vested in the crown of France, there were found on the whole island only 151 white inhabitants, 53 free negroes or mulattoes, 525 slaves, 64 horses, 569 horned cattle, 3 plantations of sugar, and 52 of indigo. Above fourteen years afterwards, however, an active commercial intercourse was opened with the island of Martinique, cultivation was rapidly extended, and, notwithstanding the interruption which these improvements sustained by the war in 1744, Grenada was found, in 1753, to contain 1262 white inhabitants, 175 free negroes, 11,991 slaves, 2298 horses or mules, 2456 horned cattle, 3278 sheep, 902 goats, 331 hogs, 83 sugar plantations, &c.; and in 1762, when it surrendered to the British arms, it is said to have yielded annually, together with its dependencies the Grenadines, a quantity of clayed and muscovado sugar, equal to 11,000 hogsheads of 15 cwt. each, and 27,000 lbs. of indigo. Having been finally ceded to Great Britain by the treaty of peace in 1763, a duty of 4½ per cent. upon all exported produce was ordered to be levied, in place of all customs and duties formerly paid to the French king; a measure which gave rise to a great constitutional question, in which, after a long and elaborate law discussion, judgment was given by Lord Mansfield against the crown, and the duty was abolished in Grenada and the other ceded islands. Great commotions and divisions also were excited in the island, respecting the election of Roman Catholic inhabitants as members of assembly. By these party-contentions, the colony continued to be disturbed till its recapture by the French in 1779: and they were again renewed, with additional violence, after its restoration to Great Britain in the general pacification which took place in 1783.

The island of Grenada is divided into six parishes, viz. St. George's, St. David's, St. Andrew's, St. Patrick's, St. Mark's, and St. John's; and, since its restoration to Great Britain in 1783, a Protestant clergy have been established by law. Four clergymen are allotted to the whole, and each is provided with an annual stipend of 330*l.* currency,* 60*l.* for house rent, and a considerable portion of the valuble glebe lands which had formerly been appropriated to the support of the Romish clergy, for whose benefit a part of the amount is still reserved. The capital of Grenada, formerly named Fort Royal, but now St George, is situated close to the spacious bay on the west coast, already described, and is divided by a ridge into two towns; the Bay-town, in which is a handsome square and market-place; and the Carenage-town, where the principal merchants reside. On the ridge, between the two towns, stands the church; and on the promontory above it is an old fort built of stone, and capable of accommodating an entire regiment. The other towns are only villages or hamlets, which are generally situated at the bays or shipping places.

The governor of the island is also chancellor-ordinary and vice-admiral, and his salary is 3200*l.* currency per annum, which is raised by a poll-tax on all slaves.* The council consists of twelve members, and the assembly of twenty-six. A freehold or life estate of fifty acres in the country, and of fifty pounds house rent in the capital, qualifies for a representative. An estate of ten acres in fee, or for life, or a rent of ten pounds in any of the country towns, and a rent of twenty pounds out of any freehold or life estate in the capital, gives a vote in the election of the representatives. The law courts, besides those of chancery and ordinary, in which the governor presides, are the court of grand sessions of the peace, held twice a year, in which the person first named in the commission of peace presides; the court of common pleas, in which a professional judge, with a salary of 600*l.* presides; the court of exchequer, lately fallen into disuse; the court of admiralty, and the court of error, composed of the governor and council, for trying appeals. In all cases the common statute law of England is the rule of justice, unless where particular laws of the island interfere.

The white population of Grenada has decreased considerably since it came into the possession of the British. In 1771 their number was above 1600; in 1777, they had diminished to 1300: and in 1791, they were not supposed to exceed 1200. Of these about two-thirds are able to bear arms, and are incorporated into five regiments of militia, with a company of free blacks, or mulattoes, attached to each. There are likewise about 500 regulars from Great Britain, for the defence of the island. The negro slaves, also, which, in 1779, were stated at 35,000, including those which were in the smaller islands, were found, in 1785, to have decreased to 23,926. The free people of colour amounted, in 1787, to 1115, whose evidence is received in the courts of law, upon proofs of their freedom being produced: and who are allowed to possess lands or tenements to any amount, provided they are not aliens.

There are 80,000 acres of land in the island, but only 50,000 were brought into cultivation in 1791. The face of the country is mountainous, but every where accessible, and well provided with rivulets and springs. On the west side, the soil is a rich black mould, lying on a substratum of yellow clay; on the north and east, it is a brick mould; on the south, and in the interior, it is of a reddish hue, and generally poor. In 1776, the exports from the island and its dependencies were 14,012,157 lbs. of muscovado, and 9,273,607 lbs. of clayed sugar; 818,700 gallons of rum; 1,827,166 lbs. of coffee; 457,719 lbs. of cocoa; 91,943 lbs. of cotton; 27,638 lbs. of indigo, and some smaller articles, the whole of which, at a moderate computation, was worth, at the ports of shipping, 600,000*l.* sterling. The sugar was the produce of 106 plantations, worked by 18,293 negroes, which gives rather more than a hogshead of muscovado sugar of 16 cwt. from the labour of each negro,—a return which Mr Edwards affirms to be unequalled by any other British island in the West Indies, except St Christopher's. In 1787, the exports were 175,548 cwt. of sugar, 670,390 gallons of rum, 8812 cwt. of coffee, 2,062,427 lbs. of cotton, and 2810 lbs. of indigo. In 1810, the value of the exports amounted to 388,936*l.*, and of the imports to 173,366*l.*

*The following Table shews the Articles imported into Grenada in the Years* 1804, 1805, *and* 1806.

* The currency of Grenada, or rate of exchange, is commonly 65*l.* per cent. worse than sterling

The sugar plantations in this colony are subject to great ravages from the carnivorous or sugar ant, an insect which is thought to be common to all the West India islands, but which has been peculiarly destructive in Grenada. It is the *Formica omnivora* of Linnæus, and is described by Sloane as the *Formica fusca minima antennis nis longissimis.* They are of an ordinary size, a slender shape, a dark red colour, remarkable for the quickness of their motions; but are distinguished from every other species, chiefly by the sharp acid taste which they yield when applied to the tongue, and the strong sulphureous smell which they emit when rubbed together between the palms of the hands. Their numbers have often been so immense, as to cover the roads for the space of several miles; and so crowded in many places, that the prints of the horses' feet were distinctly marked among them, till filled up by the surrounding multitudes. They were never seen to consume or carry off any vegetable substance whatever, but always laid hold of any dead insect or animal substance that came in their way. Every kind of cold victuals, all species of vermin, particularly rats, live poultry, and even the sores of the negroes, were exposed to their attacks. But they were chiefly injurious by constructing their nests among the roots of the lime, lemon, orange trees, and sugar canes, and so obstructing their growth, as to render the plants sickly and unproductive. A premium of 20,000*l.* from the public treasury, was offered to the discoverer of any effectual method of destroying them; and the principal means employed were poison and fire. By mixing arsenic and corrosive sublimate with animal substances, myriads were destroyed; and the slightest tasting of the poison rendered them so outrageous as to devour one another. Lines of red hot charcoal were laid in their way, to which they crowded in such numbers, as to extinguish it with their bodies; and holes full of fire were dug in the cane grounds, which were soon extinguished by heaps of dead. But, while the nests remained undisturbed, new progenies appeared as numerous as ever; and the only effectual check which they received, was from the destructive hurricane of 1780, which, by tearing up altogether, or so loosening the roots where they nestled, as to admit the rain, almost extirpated the whole race, and pointed out the frequent digging up and consuming by fire of those stools and roots in which they take refuge, as the best preventative of their future increase. See Edward's *History of the West Indies*, vol. i.; Ablè Raynal's *History of the Indies*, vol. v.; and Gray's *Letters from Canada*, p. 379. (*q*)

GRENOBLE, a city of France, the capital of the former province of Dauphiny, and under the late government, the chief town of the arrondissement or district of Grenoble, and of the department of the Isere. This city stands at the confluence of the rivers Drac and Isere, the latter dividing it into two unequal parts; the former, which is crossed by a bridge with a single lofty arch, is liable to overflow its banks, and commit considerable devastation both in the city and its environs. Grenoble is situated at the foot of the Alps, in an agreeable country, abounding in wood and water, but of a climate so variable, that the thermometer sometimes ranges through nearly 30° in a day: the greatest heat is from the 10th of July to the 15th of August, and the greatest cold from the 20th of December to the 20th of January. The city stands 900 feet above the level of the sea, and the medium height of the barometer is 27 inches two lines. Nine-tenths of the city are on the left bank of the Isere, constituting the portion chiefly exposed to inundations, several of which have done much damage, and the water has been known to rise three feet deep in the streets.

Grenoble is surrounded by a wall, and is commanded by a citadel; but, unless its fortifications have been lately augmented, it is not considered a strong place. Within the walls, its area occupies about 64,000 square feet. It consists of 1200 or 1300 houses, and is inhabited by 23,500 souls, according to recent computations, for those of older date increase that population above a fifth. The streets are broad, and tolerably regular; and the houses, in general well built, consist of four or five stories. There are several fine public edifices, particularly the Episcopal palace, and that wherein the parliament formerly held its sittings. Among the charitable institutions which sufficiently illustrate the disposition of the citizens, the general hospital is the chief, and is governed by directors selected from the most distinguished of the inhabitants. The building, which is very spacious, is appropriated for incurables; persons insane; the indigent, who commonly amount to 400; and the foundlings of the city, about 150 in number, are also received here. This institution occupies an inclosure, to the south-east of the city, and adjoining to it is the military hospital. In the hospital of Providence, there are 60 beds, and in the hospital of the Ladies of Charity, for females, there are 20; besides which institutions, there is a poor's house in the suburbs. Grenoble has also a museum of the arts, and a botanical garden well managed. A garrison, consisting of a small body of troops, is kept here.

The principal manufactures of this city, are woollen cloths, muslins, hats, and particularly gloves, the principal towns of France, Spain, Italy, and Britain, being supplied with them. Marble cutting is also carried on to some extent, for which purpose there are mills driven by water from the adjoining rivers.

Grenoble is the see of a bishop, who formerly arrogated the title of Prince of Grenoble, and enjoyed those peculiar privileges, which, in less enlightened ages, were reserved almost exclusively for ecclesiastics. Besides the parish churches, there are several monastic institutions.

Grenoble is celebrated for the complaisance and polished manners of its inhabitants, many of whom have shewn a distinguished taste for letters. Condillac and Mably, well known among the modern literati of France, were both natives of this place. It has also to boast of having given birth to the Chevalier Bayard, characterised by his sovereign Francis I. as one *sans peur et sans reproche*, and who, if we are to credit history, singly defended the narrow pass of a bridge against 200 horsemen. The Baron Adrets, a sanguinary chief of the Huguenots, during the wars for the reformation of religion, was born here, and distinguished himself by his cruelty on the miserable prisoners who fell into his power.

As the site of this city is elevated only 15 feet above the level of the river Isere, an unusual humidity prevails, which is the source of many serious distempers among the inhabitants. Though standing at the edge of a plain, extending over a square league, and surrounded by fertile fields and gardens, these advantages are counteracted by the miasmata emanating from the depositions of the waters. Certain seasons of the year are extremely unhealthy; slow fevers are seldom eradicated; and it has been remarked, that even the children are, in infancy, of smaller size, and longer of attaining the strength and complexion of those in the neighbouring country. "The river Isere," an intelligent physician observes, "has become a kind of domestic enemy to Grenoble, with which it is necessary to live; the constant humidity, and the mud deposited by its tranquil waters in the neighbouring marshes, are inconveniences with which benificent nature has accustomed the inhabitants; but they excite less attention than the tendency of all the prevalent diseases to terminate in dropsy." It has been proposed to counteract the deleterious effects arising from local circumstances, by digging a canal to drain off the stagnant waters, and which, at the same time, would prevent the overflowing of the river; as also to deepen the bed of the Isere, in order to give it a stronger current.

Grenoble has subsisted from a very ancient period, and was known by the name of *Cularo*, under which it is designed in a letter from Plancus to Cicero. It is said to have been called *Gratianopolis* from the Roman emperor Gratian; but since the period when it was possessed by the Allobroges, and when it was denominated a city, it repeatedly changed its masters. After various revolutions, Dauphiny came under the dominion of the kings of France, and Louis XI. instituted a parliament in Grenoble, founded on the model of the parliament of Paris, since which time it has remained an integral part of the kingdom. (c)

GRETNA, or Graitney Green, is the name of a village and parish in Scotland, in the county of Dumfries. The village of Gretna, which is the first stage in going from Longtown in England, to Annan in Scotland, is built on each side of the road, and has, for more than 70 years, been famous as a place for the celebration of the clandestine marriages of English lovers. This ceremony was generally performed by a blacksmith or tobacconist, and the number of marriages have been calculated at 65, which brought in an annual income of about 1000*l.* at the rate of 15 guineas each. The remains of an oval druidical temple, occupying about half an acre of ground, has been discovered at Gretna Mains. The mansion house of Gretna hall has been fitted up by the proprietor, the Earl of Hoptoun, as an inn. The population of the parish, in 1811, was 1749.

GREW, Nehemiah, a celebrated botanist, was born at Coventry, about the year 1628, and was the son of Dr Obadiah Grew, vicar of St Michaels. At the restoration of Charles II. being a non-conformist, he went abroad, and prosecuted his studies at a foreign university, where he took the degree of Doctor of Medicine. Upon his return to England he settled at Coventry, and, in the year 1664, his attention was first directed to the anatomy of plants; and he was encouraged to proceed in this branch of natural history by his brother-in-law Dr Henry Samson, who pointed out to him a passage in Glisson's work *De Hepate*, in which this subject is represented as an unexplored, but promising line of study. In the year 1670, Dr Samson, who had seen the first book of Grew's *Anatomy of Plants*, put it into the hands of Oldenburg, who gave it to Dr Wilkins, bishop of Chester, by whom the manuscript was read to the Royal Society, under the title of a *Philosophical History of Plants*. This work was highly approved of, and was printed by that distinguished body in 1671, under the title of the *Anatomy of Vegetables begun, with a general Account of Vegetation founded thereon*. In consequence of the reputation which this work acquired for its author, Grew was invited to settle in London, where he arrived in 1671; and, upon the recommendation of Dr Wilkins, he was elected a Fellow of the Royal Society, and admitted on the 30th November 1671. At the suggestion of the same learned divine, Grew was appointed curator to the Royal Society for the anatomy of plants, which led him to draw up the 2d, 3d, and 4th Parts of his work, and the various lectures on the same subject, which form a part of his Anatomy of Plants. All these papers were composed between the years 1670 and 1676, and were read at various meetings of the Royal Society. They were afterwards collected in 1682, with 83 plates, and published in a folio volume, under the title of the *Anatomy of Plants*, a work full of the most important facts in vegetable physiology.

In the year 1673, Dr Grew published in the Transactions, a paper, entitled *Observations on Snow*, in which he supposes, that the snowy particles are formed by the drops of rain containing spirituous particles, and meeting in their descent with others of a saline, partly nitrous, but chiefly urinous or acido-salinous nature. In the year 1677, he was appointed secretary to the Royal Society, in which capacity he published the *Phil. Trans.* from January 1678 to February 1679. In the year 1680, he was made an honorary fellow of the College of Physicians, and attained to considerable practice in the medical profession.

Dr Grew drew up a catalogue of the natural and artificial rarities belonging to the Royal Society, and preserved at Gresham College, which was published in 1681 in folio, with the title of *Museum Regalis Societatis*, containing 22 plates. It was accompanied with another work, entitled the *Comparative Anatomy of Stomachs and Guts begun*, being several lectures read before the Royal Society in 1676. The description of the Museum, though by no means free from mistakes, is a work of merit, and is remarkable for an ingenious scheme or disposition of shells.

The other papers which he printed in the Transactions, were

*The Description and Use of the Pores in the Skin of the Hands and Feet.* Phil. Trans. 1684.

*Some Observations on a diseased Spleen*, Id. 1691.

*Description of the American Tomineius, or Humming Bird*, Id. 1693.

*On the Food of the Humming Bird*, Id. 1693.

*A Demonstration of the Number of Acres in England or South Britain, and the use which may be made of it*, Id. 1711.

One of the last works of Dr Grew, was his *Cosmographia Sacra*, or *a Discourse of the Universe, as it is the Creature and Kingdom of God*. The principal object of this work, was to demonstrate the truth and excellence of the sacred writings. The works of Dr Grew were translated into French and Latin. He died after a short illness on the 25th of March 1711, about the 83d year of his age.

GRIDIRON Pendulum. See Horology.

GRIES, is a mountain of Switzerland, situated in the Alpine chain which separates Piedmont from the Upper Vallais. The road over this mountain leads from Oberghestelen, in the Vallais, to Domo d'Ossola, in the Val-Maggia, and to Locarno. This road rises to the height of 7336 feet, and traverses a glacier a quarter of a league wide, and blackened by the dust of the mica slate. The distance from Oberghestelen to Formazza, at the southern foot of the Gries, is 7¾ leagues. The descent of the Gries is by four different terraces or vallies. The first is called Bettelmatte, celebrated for its fine cheese, and for the small lake from which the Toccia, or Tosa, issues. The second valley is called Morast, and from this the road descends by a very steep path to a third valley, occupied by the hamlet of the Auf der Frout, where the valley of the Toccia, or the Dolgia, commences. Another steep declivity conducts to the south valley, called Froutval, which is celebrated for the cataract of the Tosa, or Toccia, which, excepting the fall of the Rhine, is reckoned the most magnificent in Switzerland. It is about 300 or 400 feet high, and forms a species of pyramid, whose base is extremely wide, while its summit is only 4 or 5 feet in breadth. The rock is inclined about 140° or 150° to the horizon. This cataract is surrounded on all sides with lofty rocks, crowned with wood. The southern side of the Gries is inhabited by Germans as far as the village of Foppiano. The south side of the mountain is composed of gneiss, of veined granite, and of mica slate. In the valley of Egino, there are beds of potstone, which are wrought about a quarter of a league on the east side of the bridge. Slates occur to the south, and lower down the mica slate appears. The first valley is composed of gneiss and calcareous strata. Below the second valley, rocks of argillaceous schistus stretch to the north-east; and, on the other side, are rocks of a ferruginous aspect. All the rocks from the north to the south, as far as Pommat, lie in strata almost vertical, in the direction from north-east to south-west. See Ebel's *Manuel*, &c.

GRIMALDI, Francis Maria, a learned Italian Jesuit, was born in the year 1619, and cultivated the sciences along with his friend Riccioli. Grimaldi was the first person that observed the lengthening of the solar image when refracted by a prism; and he is principally known for his discovery of the diffraction of light; a subject which was afterwards examined by Sir Isaac Newton, under the name of the Inflexion of Light. These discoveries of Grimaldi are contained in his work entitled *Physico-Mathesis de Lumine, Coloribus et Iride*, Bononiæ, 1665. The principal object of this work, is to determine whether light be a substance or a quality; and, after occupying 535 quarto pages in this discussion, he concludes, with the Aristotelians, that it is not a *substantial*, but an *accidental* quality. A full account of this work will be found in the *Phil. Trans.* for 1672, No. 79, p. 3069. Grimaldi died in 1663, in the forty-fourth year of his age. The discovery of the solar spots, and the present nomenclature of the lunar spots, have been erroneously ascribed to him. See *Phil. Trans.* abridged, vol. i. p. 675, Note. See also Optics.

GRIMSBY, or Great Grimsby, is a borough and seaport town of England, in Lincolnshire, situated near the mouth of the Humber. The streets are clean, and the houses in general well built. The church, which is called St James, is spacious and handsome, and is built in the form of a cross, with a tower in the centre. The steeple is a fine specimen of English pointed architecture. A part of the choir fell down in 1600, but the steeple has scarcely suffered from the depredations of time. In the upper part of the steeple is the singular inscription, "Pray for the soul of John Empringham." The church contains many ancient monuments. Grimsby had formerly a monastery of Gray Friars, a convent of Benedictines, and a priory of Augustine canons. Grimsby was once a rich and populous town, with a considerable foreign and inland trade. It was a mayoralty in the reign of King John; and in the reign of Edward III. it furnished 11 ships and 170 mariners to assist at the siege of Calais. The harbour, however, was gradually choked up, and a dangerous sand bank having drifted near its mouth, its trade declined, and was transferred to Hull. Of late, the trade of the place has revived; the harbour has been improved, a dock constructed at great expence, and the town enlarged by additional buildings. A small coasting trade is carried on with sloops. Salt and coals are the chief articles of importation. There was once at Grimsby a castle, but it is entirely decayed. There are some very extraordinary fountains near the town, called Blow Wells, which never overflow, though they rise to a level with the surface of the ground. Grimsby is a port town under that of Hull, and has a deputy collector, comptroller, and coast surveyor. The Grimsby canal is a short canal, which leads from the Humber to Grimsby wet docks. Population of the burgh and parish, in 1811, 2747. See the *Beauties of England and Wales*, vol. ix. p. 689, &c.

GRIMSEL, is the name of a lofty mountain in Switzerland, over which there is a road from the canton of Berne into the Upper Vallais. The distance from Meyringen on the Aar, to the Hospice of Grimsel, is about seven leagues, and from thence to Oberghestelen on the Rhone, is three leagues. This road is bordered in several places with frightful precipices, and it is often necessary to pass over bridges apparently insecure.

After leaving Meyringen, the traveller passes through the forests of Mount Kirchet, by the agreeable valley of Im Grund. The gneiss here appears below the calcareous strata, lying above the primitive rock. The strata of the gneiss are almost vertical, a little inclined to the south. Beyond the forest which occupies the extremity of Grund, the calcareous rocks cease altogether, and the gneiss and micaceous schistus replace it on the side of Guttaner, the southern dip of these rocks being a little increased. In the valley of D'Urbach, the great glacier of D'Urbach or of Gauli descends into the plain; and after passing the Aar by a bridge, a rough and solitary path cut out of the rock leads between the mountains of Urbach, Ritzli, Gauli, and Gouttan, to the hamlet of Im Boden, and thence to the village of Gouttanen, situated 3196 feet above the level of the sea, where there is a tolerably good inn. This village was burnt in 1803, but, in consequence of the liberality of the Swiss, it has been rebuilt. About a quarter of a league above Gouttanen, the granite appears in mass, and extends to the Grimsel. Its stratification is distinctly seen. At first the strata stretch from north-east to south-west, and afterwards from east-north-east to west-south-west. About half a league from Gouttanen, the Aar forms a cascade at the side of the road; and a fine rainbow may be always seen in clear weather between ten and two o'clock. Beyond Gouttanen the road passes Mount Stampf, and, after twice crossing the Aar, the traveller reaches the chalet of Handeck in two hours. The glacier and the lake of Ghelmer are distinctly seen from that mountain to the east, and to the south-west appear the glaciers of Erlen and Ritzli, and the Handeckhorn to the south. At a considerable distance below the chalet, the Aar forms one of the finest waterfalls in Switzerland. It should be visited during sunshine, between half-past nine and eleven o'clock, and from the bed of the river, as near the bottom of the fall as possible. From Handeck to the Hospice is a distance of two leagues, over a terrible road, which is three times crossed by frightful though substantial bridges. About half a league from Handeck appear immense rounded surfaces of granite, in which steps have been cut for the feet of the horses and of travellers. After travelling half an hour longer, we cross the fine Alpine pastures of Roderischboden. At the last bridge, not far from the Hospice, the Aar suffers another remarkable fall.

The Hospice, which was built in 1557, is surrounded with frightful rocks, and is situated at a height of 5628 feet above the level of the sea. The keeper of it is allowed to hunt in any of the cantons of Switzerland, and is bound, in return, to feed and lodge all travellers that cross the Grimsel. He remains at the Hospice from March till the beginning of November. He can furnish seven good beds, though there are sometimes more than a hundred candidates for them. Near the Hospice is a small lake called Kleinsee, from thirty-two to sixty-two feet deep. The Sassbach throws itself into the lake in a fine cascade. After leaving the Hospice, the road continues to ascend for three quarters of a league, and at its most elevated point the height is 6570 feet. The height of the Seidelhorn, which is the highest summit of this mountain, is 8580 feet. From the highest part of the road, there is a fine view of the Furca, of the Galenstock, of the peaks of St Gothard, of the Gries, and of the southern chain of the Vallais, as far as Mont Blanc. The descent to Oberghestelen occupies only about two hours.

On the top of the Grimsel a reddish granite occurs;

mica slate appears in the southern face; and argillaceous schistus at the southern foot of the mountain. A singular grotto, filled with crystals, was opened on Mount Jochli, upon the Zinkenstock, in 1720. It was the richest ever found in Switzerland: It was 120 feet deep and 18 wide, and contained crystals, of which a small number weighed nearly eight quintals, and several four or five quintals. Several thousands of quintals were obtained, of the estimated value of 30 000 florins. One of the largest of these was $3\frac{1}{2}$ feet diameter, $2\frac{1}{2}$ feet long, and one of its six faces $1\frac{1}{2}$ feet wide. It is now in the museum of Natural History at Paris.

The glaciers of the Aar are generally visited by the travellers that cross the Grimsel. In the month of August 1799, the French ascended the mountain, and, after a severe conflict, drove the Austrians from their position on its summit. See Ebel's *Manuel, &c.*

GRINDELWALD is the name of a village of Switzerland, in the canton of Bern. It is situated in a rich Alpine valley, at the height of 3150 feet above the level of the sea. The direction of the valley is N. E. and S. W. and it is encircled with lofty mountains. The Faulhorn, to the north of Grindelwald, is 8020 feet high; the Wetterhorn, to the east, is 11,433; the Eiger, to the south, is 12,268. The Schreckhorn, to the south-east, is 12,530 feet; and the Jungfrau, to the S. S. W. is 12,840 feet. The valley is shut up at the north-east by the Scheideck, which is 6045 feet high.

This valley is one of the most frequented in Switzerland, both from its proximity to Bern, and from the facility with which its two glaciers may be visited. These glaciers are parallel to each other, and are each about a league distant from the Inn. The smaller glacier forms an arm of the immense valley of ice which is situated between the Schreckhorn, the Viescherhorn, and the two Eigers. In the middle of this glacier there is a rock, almost vertical, on which the snow cannot rest, and which has, therefore, received the name of the *warm rock*. The surface of the glacier is extremely unequal, and is formed into many splendid pyramids of ice. Near it is a wood of elder trees, where excellent strawberries may be gathered almost close to the ice.

The great or upper glacier, almost entirely separated from the small one by the rocks of the Schreckhorn, lies between the Mettenberg and the Wetterhorn. Its ancient limits were formed by a hill of debris, thirty feet high, and covered with pines of considerable height. In 1720, the glacier extended thus far, but it afterwards retired, and the space which it left was covered with trees. A new augmentation, however, which it experienced in 1780, destroyed this wood. The torrent which flows from it is the Black Lutschinen. In this valley the traveller frequently hears the thunders of the glaciers, and experiences the violence of the winds which issue from their crevices.

The road from Grindelwald to Meyringen, in the valley of Hasli, by the Scheideck, is extremely interesting. It is only a distance of seven leagues, and may be performed on horseback without any danger. See Ebel's *Manuel, &c.*

GRINDING OF DRUGS. See DRUG MILL.

GRINDING AND POLISHING OF PLATE GLASS. See GLASS, Sect vi.

GRINDING OF LENSES AND MIRRORS for optical instruments. See OPTICS.

GRINSTEAD, EAST, is a borough and market town of England, in Sussex. It is pleasantly situated on a hill, near the northern border of the county. The town is irregularly built, but it contains many neat modern houses. The church, which stands on the east side of the main street, is a spacious and handsome structure. It has a lofty and well-proportioned tower, adorned with pinnacles at the corners. Sackville college, a large quadrangular stone building, stands at the east end of the town. It was built in 1616, as a charitable institution, for the support of 24 old persons of both sexes. A suite of rooms is set apart for the Duke of Dorset, who gave the use of them to the judges when the assizes were held here. There is here a neat chapel belonging to the college, and also a free school here for 12 boys. Population, in 1811, 2804. See *Beauties of England and Wales*, vol. xiv. p. 150.

GRINDSTONES, from the Latin *Gyrandus*, are circular stones, a few inches thick, which are mounted on a spindle, and turned with a common winch, for the purpose of grinding edge tools. When a great number of these stones are driven by machinery for the purpose of cutlery, they are called *blade mills* or *grind mills*. Grindstones are formed of a gritstone, in which the grains of silex are firmly cemented to each other by a siliceous or other hard cement, the interstices not being filled up as in other kinds of sand stone. The following is a list of the grindstone quarries in England, with their degrees of fineness, drawn up, we believe, by Mr Farey, for Dr Rees's *Cyclopædia:*

Ashover, N. W. (hill quarry) Derbyshire, middling.
Beely Moor, E. of the town, Derbyshire, coarse.
Belper, S. E (Hungerhill) Derbyshire, middling.
Biddulph-Hall, N. W. of Leek, Staffordshire, coarse.
Bilstone, S. E. of Wolverhampton, Staffordshire, middling.
Bolsover, N. W. (nunnery) Derbyshire, middling.
Bredsal Moor, N. of Derby, middling.
Brinclif-edge, S. E. of Sheffield, Yorkshire, fine.
Buxton, N. (Corbar) Derbyshire, fine.
Darley Moor, E. of the town, Derbyshire, coarse.
Gate-head fell, $2\frac{1}{4}$ miles south from Chester Ward, Durham.
Glossop, Derbyshire, coarse.
Harthill, S. E. Yorkshire, fine.
Hooton-Roberts, near Rotherham, York, middling.
Horsley, N. of Derby, fine.
Lane-top, N. of Sheffield, Yorkshire, whitening.
Little Eaton, N. of Derby, coarse.
Milford, S. of Belper, Derbyshire, coarse.
Molecopt-hill, S. of Congleton, Cheshire, coarse.
Morley-moor, N. of Derby, fine.
Norton, W. (Hemp-yard lane) Derbyshire, fine.
Overton (Gregory) in Ashover, Derbyshire, coarse.
Polesworth, S. E. of Tamworth, Warwick.
Purton, W. of Wolverhampton, Staffordshire, fine.
Ridgeway (Lum-delph) in Eckington, Derbyshire, fine.
Stanley, N. E. of Derby, fine.
Stanton by Dale, E. of Derbyshire, fine.
Stanton Moor, N E. of Winster, Derbyshire, coarse.
Therberg, near Rotherham, Yorkshire, fine.
Treton, ditto, ditto, fine.
Warton E. of Tamworth, Warwickshire.
Wickersley, near Rotherham, Yorkshire, middling.
Wokes, near Barnsley, Yorkshire.

The most extensive grindstone quarries are those near Gateshead. They are sent to all quarters of the globe, under the name of Newcastle grindstones, and constitute a great branch of the trade of Newcastle and Gateshead.

The explosion of grindstones when in motion is a phenomenon which has frequently happened, and which has been attributed to the effect of the centrifugal force, and to the expansion of the wooden wedges. On the 8th June 1768, a very singular accident of this kind happened to a cutler at Ivry-sur Seine, near Paris, who was grinding kitchen utensils. The stone flew into the air apparently on fire, and burst into innumerable fragments, with a dreadful noise. One of the fragments, of about three pounds weight, flew over a building 40 feet high, and alighted 108 feet beyond it in the garden, where it broke the branch of a lime tree. Another fragment, of nearly the same size, grazed the parasol of a young lady who was standing beside the cutler. A part of the stone was found upon the pavement reduced to powder. A similar accident happened to a cutler at Strasburg, who was killed by the explosion.

Our readers will find some curious facts relative to grindstones, and to their sudden explosions while they are at work, in the *Encyclopedie Methodique*, art. TOURNEUR; *Collection Academique*, tom. xiii. p. 45 48, 413. and tom. xii p. 109; *Mem. Acad. Par.* 1762. *Hist.* p. 37; and *Id.* 1768.

GRISONS, the *Upper Rhetia* of the ancients, is the name of a republic which was formerly independent, but since the year 1798 it has formed one of the nineteen cantons of Switzerland. It is bounded on the north by the canton of Glaris, from which it is separated by a chain of mountains, and by the German districts of Schweiz, and the Voralberg, in Suabia; on the east by the Tyrolese; on the south by the Valteline, and the Ticino; and on the west by the canton of Uri.

This canton is the largest in Switzerland. It contains 140 square geographical miles (15 to a degree), and comprehends no fewer than 60 principal and lateral vallies. From its most eastern part, at Finstermunz on the Inn, to the Mountain Badus at the source of the anterior Rhine, is 32 leagues; and from its most northern part at the Mountain Seesa Plana, to its most southern part near the Mountain St George, is 23 leagues.

The natural divisions of the Grisons form five great vallies, viz. the valley of the Posterior Rhine, the valley of the anterior Rhine, the valley of the Inn or the Engadin, the valley of the Albula, and the valley of the Landquart, or the Prettigau.

1. The valley of the Posterior Rhine includes the vallies of Rhinwald, Schams, Via Mala, and Domlesch. The Rhinwald is about eight leagues long, and is surrounded on all sides by lofty mountains. It is accessible only by one road, which passes through the defile called Rofflen, which leads into the valley of Schams. The surrounding mountains, of which the Avicula and the Piz-val-Rhin are 10,280 feet high, are covered with enormous glaciers, and the valley is exposed to frightful avalanches. The winter continues nine months. The grass does not begin to grow till the end of June, and it is necessary that the hay be got in before the beginning of September. This valley is inhabited by Germans of the Suabian colony, which the Emperor Frederick I. sent, at the end of the 12th century, to ensure a passage into Italy over the Splugen. The two principal roads for crossing the Alps pass through the Rhinwald; one of them over the Splugen, and the other over the Bernardin. In taking the road over the Splugen, eighteen hours are necessary to go from Coire to Chiavenna. From the village of Splugen, the road follows the brook Hansle all the way to the inn on the summit of the hill on the Italian side, which is a distance of three leagues. The height of the road is here 6170 feet; but that of Tombo-horn, the neighbouring summit of the mountain, is 9795. The gorge called the Cardinell is truly horrifying and dangerous. The road then follows the impetuous course of the Lira, and the traveller arrives in two hours at Isola. In two hours more, after passing through the valley of St Jacques, and by Campo Dolcino, where the custom-house officers examine all baggage, he reaches Creston, and then Sta Maria, which is only a league from Chiavenna. General Macdonald crossed this mountain in 1800, between the 27th of November and the 1st of December, and lost many men and horses by the avalanches. The northern side of the Splugen is chiefly composed of gneiss and micaceous schistus. Very fine white marble occurs near the summit of the road. It stretches between the micaceous schistus from south-west to north-east. The inhabitants of the village of Splugen make very fine articles of it. There were once two roads over the Bernardin, but the shortest is passable only in summer. The longest is kept in repair by the commune of Hinter-Rhein. At the highest part is a Hospice, which is three hours distant from the village of Hinter-Rhein on the north, and two hours from the village of Bernardin, in the valley of Misox, on the south. The small lake of Muesa, with several islets, is situated on the summit of this mountain. The water that runs from the southern face of the glacier of the Rhine throws itself into this lake, which again forms the brook of Muesa, and, after running through the valley of Misox, joins the Tesino at Bellinzone. This mountain is composed of gneiss. It was crossed in 1797, on the 7th March, by the French army under General Lecourbe.

In entering the Rhinwald from the valley of Schams by Rofflen, the road passes the villages of Suvers, Splugen, Medel, Ebi or Planura, Noveina or Noufenen, and Hinter-Rhin. The church of Hinter-Rhin is 4770 feet above the level of the sea. From the very bottom of this valley, which extends itself, with a singularly wild aspect, among the horrible rocks of Avicula and the Piz-val-Rhin, the glacier of Rhinwald and the source of the posterior Rhine may be distinctly seen, and can be reached in three hours from Hinter-Rhin. From a station a little way beyond the chalets of Tessini upon Zaport, may be seen the basin formed by the rocks of the Black Muschelhorn, and by a ridge of mountains about two leagues long, from which 13 torrents descend. At the bottom of this basin lies the glacier of Rhinwald. The torrent of the glacier issues from a magnificent vault of ice, and receiving the 13 brooks already mentioned, it forms the true source of the posterior Rhine. On leaving this deep gorge, it receives 16 torrents before reaching Splugen. After this it escapes through the gorge of Rofflen, receives other six brooks from the valley of Schams, throws itself into the abysses of the Via Mala, and still farther enlarged in the valley of Domlesch by ten tributary streams, particularly the Albula, it joins itself at Reichenau to the anterior Rhine, which is considerably less in size, though enlarged by nearly 30 torrents. The Via Mala is one of the most frightful defiles in Switzerland. It extends two leagues from Tousis to Zilis. See VIA MALA.

The valley of Schams, which is two leagues long, contains eight or nine considerable villages, on both sides of the Rhine. It is lower and more fertile than the Rhinwald, and is one of the richest and most populous in Switzerland. See SCHAMS.

The valley of Domlesch, or Tomleasca, is formed by the posterior Rhine, after its junction with the Albula, and before it falls into the anterior Rhine. It is about two leagues long and one wide, and is the most temperate in the Grisons. It derives much of its celebrity from the picturesque and cultivated mountain of Henzenberg, about two leagues long, and stretching along the west side of the valley. The northern entrance to the valley is scarcely 100 paces wide; and on the south it is shut up by the Beverin and the Mouttnerhorn, between which the river forces itself with great fury. Soon after it receives the black stream of the Nolla, and half a league lower that of the Albula. The valley of Domlesch contains no fewer than 22 villages, and 12 ruined and inhabited castles, some of which are remarkable for their antiquity. Excepting at Tousis, the Romansh is here the general language. The base of the mountains is composed of argillaceous schistus, covered with calcareous schistus. Gypsum appears in vertical beds in the Via Mala, and in the western part of the valley. See Tomils and Tousis.

2. The anterior Rhine comprehends the valleys of Tavetsch, Medels, Sumvix, Lugnetz, Petersthal, &c. The valley of Tavetsch forms the upper part of the anterior Rhine. Sadrun is the principal place. Ruaras is the highest Grison village in the south-east. Selva and Camot are the only other places of note. The anterior Rhine is formed by three branches, which unite at Camot. The middle branch comes from the mountain Badus, and is called Rhin-de-Camot. It is formed by the glaciers on the eastern side of that hill, which throw their waters into the small lakes of Lac-de-Toma and Lac-Palidulca, and form the branch already mentioned. The second branch, called the Rhin-Cornara, flows out of the valley of the same name, having risen in the mountains of la Sceina de la Reveca. The third branch comes from Kamerthal, and rises at the foot of the Crispalt. The anterior Rhine, formed by these branches, receives ten brooks before it falls into the middle Rhine, which flows through the valley of Medels. Badus is 9085 feet above the bottom of the valley. It is accessible from the north, south, and east, and commands a grand view of the distant Alps. From Camot and Selva, this mountain may be ascended and descended in one day. The valley of Tavetsch is peculiarly exposed to avalanches. In 1749, an avalanche came from Crispalt, a mountain two leagues distant, and overwhelmed 100 persons, of whom 80 were taken out of the snow alive. On the night of the 13th December 1808, another descended from Rouenatsch on the village of Selva, and killed 42 persons, and 237 cattle.

The valley of Medels is very narrow and picturesque. It is watered by the middle Rhine, and extends five or six leagues. Wheat, barley, flax, and hemp, are here cultivated; but the care of the cattle is the principal concern of the inhabitants. Very fine cheese is also produced in this valley. Beyond the junction of the middle and anterior Rhine, the valley is for $1\frac{1}{2}$ miles very narrow and dark, owing to the height of the rocks, and the fir trees which cover them. The middle Rhine runs in a very narrow channel, and forms many fine cascades. In leaving this defile, the smiling valley of Medels appears. The village of Kurajla is seen situated above the river; and on the left the lateral valley of Platas, which contains the hamlets of Soliva and Bisquolm. At the Hospice of St Maria, on the Lucmanier, the Val-Kadelina opens, in which the middle Rhine has its origin. See Lucmanier.

The valley of Sumvix opens into the Rhine opposite the village of Sumvix, and has the village of Surhein at its mouth. It is about five leagues long, and stretches between huge mountains covered with glaciers. It is rich in mountain pastures, meadows, and forests. The mountain of Tenija, situated at the upper extremity of the valley, divides it into two branches, viz. Val-Vijlots and Val Greina. The torrent which runs through the valley, has its origin in the vast glacier of Medels. Though the valley is more fertile than that of Medels, it has only two chapels, and 121 inhabited houses. There is a sulphureous spring half a league above Surhein. The view of the cascade of the Greina, and the surrounding glacier, is particularly admired.

The valley of Lugnetz opens into the Rhine near Ilantz (See Ilantz.) It is eleven leagues long, and contains many lateral vallies. From Ilantz to the central point where the valley divides, is three leagues. To the south-west of this point stretches the valley of Urin, and to the south-east that of St Petersthal. The greater part of the inhabitants are Catholics. See Lugnetz.

The road from Dissentis to Coire, along the banks of the Rhine, is extremely interesting. The Benedictine abbey of Dissentis is situated above the town of the same name, on the northern face of the mountain Vakaraka, whose great forests protect both it and the town. It enjoys a splendid view of the Rhine as far down as Coire. It was founded in 614, by Sigebert, a Scottish Benedictine, who came to preach Christianity to the Rhetians. Placide Toparcha of Trons gave him the ground for this purpose, and became himself a monk. The convent and a part of the town were burned by the French in May 1799, and the inhabitants were put to the sword, in consequence of the women having massacred a company of soldiers without arms in a general insurrection. A collection of books and precious manuscripts, and the mineralogical collections and journals of R. P. Placide a Specha fell a prey to the flames. The convent has been rebuilt, and the Catholic school of the canton has been established here since 1804. The town is the chief place of the district of Dissentis, which is one of the most ancient and populous of the Grey league. From Dissentis to Trons is a distance of 3 leagues. The best wheat in the Grisons grows about Sumvix. The mountains are all primitive to Trons, but to Ilantz they are composed of beds of calcareous stone and schistus. To the north of Trons (See Trons) opens the wild valley of Puntajlas, indented with glaciers, from which issue the torrent of Ferrara. From Trons to Ilantz, by Tavenas and Rauvis, is a distance of four leagues, through a very narrow valley The great road recrosses the Rhine below Tavenas, and passes by Rauvis, Schlowis, Sagens, Lax, Flims, Trins, and Tamins to Reichenau. At Rauvis, a league below Ilantz, is a mine of galæna, containing silver. The galæna is in masses of gneiss. At Obersax, a village on the other side of the Rhine, there is a mine of pale red copper, containing much silver. There is also here abundance of borax. These two mines have been wrought since 1806. The road through Scholwis, Sagens, and Lax, traverses thick forests of Pines, and a wild country, diversified with grain and pastures. At Flims, which is situated on beautiful hills, in a pleasant place, and also at Tamins, the houses stand in separate clusters. Flims is remarkable for the beauty of its inhabitants, and for the excellence of its springs of water. The torrent Blaun sometimes commits dreadful ravages. From Flims to Elm, in the canton of Glaris, is $7\frac{1}{2}$ hours by the Hunter's road. Reichenau is the key of the anterior Rhine, and is situated at the confluence of the posterior and anterior Rhine. The former has an ash-grey colour, and the latter is a limpid green. See Reichenau.

The road from Reichenau to Coire or Chur by Ems, is a distance of 2 leagues. Between Reichenau and Ems, are 15 or 20 conical hills, covered with oak, and adorned in the most picturesque manner by chapels and ruins. From Ems to Coire is a fine rich valley, bounded on the right by the mountains of Malix, and on the left by the Galanda. This mountain is 6598 feet high, and rises like an enormous pyramid. It is ascended most easily on the side of Coire. It is composed of calcareous rocks, and of calcareous schistus, containing much argil. The strata are inclined to the south. Coire is situated on the left bank of the Rhine, in a rich plain between 2 or 3 miles wide. The town lies partly in the plain, and partly on the steep side of a rock. It is encircled with ancient brick walls, strengthened with round towers. The streets are narrow and dirty. The bishop's palace and the cathedral, built in the 8th century, stand in the highest part of the town. The convent of St Lucius is situated above the palace. The library of the town, an institution for the poor, the cantonal school, are the other principal establishments. In 1806, about 200 copper medals of the Roman emperors were found near the anterior gate. The plain around Coire is diversified with corn and pasture, and the sloping hills are covered with vines, which yield a pleasant but not a strong wine. The population of the town is 3000. Rafts, carrying from 20 to 50 quintals, descend the Rhine from the bridge over the Albula to the Lake of Constance.

Below Coire, the road passes through the fine villages of Masans, Trimmis, Zitzen, and Ighis, to the chateau of Marschlen, where the Messrs Salis have a fine library, and a superb cabinet of natural history. The Economical Society of the Grisons was established at Zitzen in 1778, and had published nine fasciculi in 1803. The road now crosses the Lanquhart by the bridge of Zollbrucks, where there is a pontage, and passes through Malantz, Jennins, and Mayenfield. Malantz is a small handsome town on the side of a hill. Its red and white wines are reckoned the best in the Grisons. There are beds of gypsum near Jennins, and much blue marl in the neighbourhood. Jennins is half a league from Mayenfield, and three quarters of a league from the defile of Luciensteg. The fine valley of Mayenfield is a league wide, and is surrounded with lofty calcareous mountains. The defile of Luciensteg is situated near the northern frontier of the Grisons, on the side of Suabia, between the Gouscher Alp, 5573 feet high, and the Flesch, 3114 feet high. A wall 100 toises long, and a rampart of the same length, defends on that side the entrance to the Grisons. The frontier passes near Balzeres, situated on that defile. At the village of Gouscha near Luciensteg, the mothers are accustomed to tie their children to a rope of a certain length, when they are obliged to leave them at home, lest they should fall over the precipices.

3. The valley of the Inn, or the Engadin, is one of the finest in Switzerland. It has 28 lateral vallies, several of which have two or three ramifications. It stretches from the south-west to the north-east, and is 18 leagues long from the Maloggia to the bridge of St Martin. It is divided into the higher and the lower Engadin. The former is seven leagues long, from the mountain Maloggia to that of Cassanna, and the latter is 11 leagues long, from Brail to the bridge of St Martin. It is subject to frequent earthquakes. A full account of this interesting district will be found in our article Inn.

4. The valley of the Albula comprehends the valleys of Davos and of Oberhalbstein. The principal valley of Davos is five leagues long, and is watered by the Landwasser, which falls into the Albula near Filisour, the end of the valley, where the river runs through a defile 1200 feet deep. The lateral vallies of Davos are those of Flula, Dischma, and the fine valley of Sertig, which is divided into two, and has a sulphureous spring, and another mineral water of a purgative quality. Each of these three vallies is four leagues long. Opposite the gorge of Zughen is the valley of Montstein, which has two branches, each a league in length. The district of Davos contains six lakes; the greatest of these, which is half a league long and a quarter wide, contains great quantities of fish. This district possesses several mines of galæna, copper, lead, and iron. The river Albula issues from a small lake in a mountain of the same name, over which there is a road to the Engadin. It descends into the valley across a dreadful gorge, called the rock of Bergun or Bergunerstein, and meets the Landwasser at Filisour. Though the smallest of the two, the united stream is called the Albula. It receives the Rhin-d'Oberhalbstein at Tiefenkasten, and is then lost in the posterior Rhine at Furstenau.

The valley of Oberhalbstein lies on the northern face of the mountains Septimer and Julier. It is 8 leagues long, and its river rises in a small lake on Mount Septimer. Savognin is the chief place in the valley. About Tintzen the valley grows very narrow, and the road ascends at the side of a torrent, bounded by horrible rocks. At the end of three-fourths of an hour it enters the meadows of Rofna. Near Molins, the castle of Splondatsch appears at the bottom of a frightful gorge. On the road to Marmels, the ruins of the castle of the ancient lords of Marmels rise on the right, upon the summit of lofty rocks. There is a mine of silver and of tin near Ziteil; and the remains of a copper mine between Ochsenberg and Tintzen.

5. The valley of the Lanquhart, or the Prettigau, is 8 leagues long and 4 wide, and has 9 or 10 lateral vallies. An account of it will be given under Prettigau. For still farther topographical information respecting the Grisons, see Misox, and the other articles already referred to.

The Grisons are divided into three leagues. 1. The League of God's House; 2. The Grey League; and, 3. The league of the Ten Jurisdictions.

The League of God's House is divided into 11 districts, and 21 communes, and sends 22 deputies to the general diet. Coire is the capital. The jurisdictions are,

| | |
|---|---|
| 1. Coire. | 7. Obervats. |
| 2. Pregalia. | 8 Oberhalbstein. |
| 3. Upper Engadin. | 9. Puschiavo. |
| 4. Lower Engadin. | 10. Munster. |
| 5. Bivio or Stalla. | 11. Villages of Zitzen, Ighis, Trimmis, and Unter Vatz. |
| 6. Ortenstein. | |

The Grey League is divided into 8 high jurisdictions and 27 communes, and sends 32 members to the general diet. The following are the jurisdictions:

| | |
|---|---|
| 1. Dissentis. | 5. Flims. |
| 2. Valley of Lugnetz. | 6. Rhinwald and Schams. |
| 3. Grub. | 7. Henzenberg and Tousis. |
| 4. Waltensburg. | 8. Misox. |

The League of Ten Jurisdictions is composed of 11 communities, and sends 14 members to the diet. It comprehends the rest of the Grisons, viz. the vallies of Davos, Prettigau, Mayenfield, &c.

These three leagues are connected by an annual diet of the congress and of the three chiefs. The diet consists of 63 deputies, who are chosen in the several communities by every male above a certain age. The diet meets about the beginning of September at Ilantz, Coire, and Davos, in rotation, and sits three weeks or a month. The chief of the league, in whose district the diet is held, is president, and has a casting vote. In all affairs of importance, the deputies act according to the instructions of their constituents. A majority of votes decides every thing; but they vote in the following manner: When the communities send instructions, the secretary reads them aloud, and the votes are taken from these instructions. In all resolutions, respecting which instructions are not received, the deputies may vote as they please; but these resolutions are subject to the revisal of the communities. For this purpose, a congress is held in February or March at Coire, consisting of the three chiefs and three deputies from each league, for the purpose of receiving the votes of the different communities relative to the questions referred to them at the preceding diet. The three chiefs, and the other members of congress, receive 54 florins, about 4*l*, to defray their expences. The deputies to the general diet receive a salary, which never exceeds five shillings a day.

The three chiefs meet three times in the year at Coire, and send information to the different communities respecting the subjects of discussion at the general diet.

The Roman law, modified by municipal customs, prevails in the three leagues. It appears from the concurring testimony of several travellers, that the administration of justice, both in the civil and criminal courts, is very imperfect. The judges are capable of being bribed; and confessions are obtained by torture.

The public chamber of justice, called the *Strattgericht*, is a court composed of ten judges out of every league, and twenty advocates. It is assembled by a demand made by the peasants to the general diet, and is paramount to all law. There is no appeal from the decisions of this inquisitorial tribunal. The worst effects resulted from the meeting of this court, but fortunately it is now gone into disuse.

The Catholic and Protestant religions both prevail in the Grisons. The Protestants form about two-thirds of the population. There are 135 Protestant parishes, viz. 53 in the League of God's House, 46 in the Grey League, and 36 in the League of Ten Jurisdictions. The livings are from 6*l*. to 25*l*. per annum. The clergy are here obliged to increase their income by traffic; and their poverty is rendered more oppressive from their dependence, as they are generally chosen by the people. Several of the ministers are, however, very respectable, and well informed. The Protestants are educated at Zurich and Basle; and the Catholics at Milan, Pavia, or Vienna. A Latin school was established at Coire for the children of the burghers; and another in 1763, for those intended for the church.

The expenditure of the government consists merely in the salaries of the deputies, and in the expences incurred at the sitting of the diet. The revenues are drawn from the duties upon merchandise, which passes through the canton of the dependent states, and was farmed at 17,000 florins, or 1259*l*.: from fines upon delinquents; from a tribute of 500 Philips, or 125*l*. from the Valteline; and 100 Philips, or 25*l*. from Chiavenna; and from the interest of a small sum, the principal part of which, viz. 4000*l*. was vested in the British funds.

The commerce of the Grisons is very limited. Its principal exports are cheese and cattle, and some planks, stones, and coal, to Milan. The care of the cattle is the principal employment of the peasantry. The canton possesses 8000 head of great cattle, about 30,000 cows, from 60,000 to 70.000 goats, and nearly 100,000 sheep, which come annually from Italy to feed upon the fine pastures of the Grisons. The cattle of the Prettigau are the finest breed. Vines are cultivated in the vallies on the northern and southern frontiers.

The imports of the Grisons are grain, rice, salt, and silk stuffs from Milan; grain from Suabia and the Tyrol; salt from the Tyrol and Bavaria; fine linens and muslins from Switzerland; and English, French, and Silesian fine cloth through Germany. The only manufactory in the country, is that of cotton at Coire. The trade of the Grisons, and the subject provinces, is carried on with Milan across the Lake of Como, by its branch the lake of Lecco, by the river Adda, and by the canals of the Adda and the Trezzo.

The Italian, German, and Romansh languages, prevail in the Grison territory. The inhabitants of Pregalia and Puschiavo, and of the vallies of Misox and Calanca, speak the Milanese dialect of the Italian tongue. The inhabitants of the Ten Jurisdictions, with the exception of a few villages; those of the League of God's House, at Avers, Coire, and the four villages; those of the Grey League, at Splugen, Cepina, and other villages of the Rhinwald; at Valts, in the valley of St Pedro; at Tousis, Reichenau, Feldsperg, Tamins, Meyerhof, Versam, and Valendros.

The Romansh, or Rhetian language, is the vernacular tongue throughout the greater portion of the Grison territory. It was formerly spoken at Coire, and the adjacent districts, and as far as Inspruck in the Tyrol. It is divided into two principal dialects; the one called Cialover, spoken in the Grey League; and the other Ladin, in that of God's House. These dialects vary both in pronunciation and orthography, and they have a great affinity to the Latin, and other languages derived from the Latin. Planta seems to have proved, that the Romansh of the Grisons is the same with the ancient Romansh, called *Lingua Romana*, the mother of the French tongue. It was the earliest language derived from the colloquial Latin, and was understood in Italy, in the Morea, and at Constantinople, having been universally diffused throughout the south of Europe in the 11th and 12th centuries.

The antiquities in the Grisons are very numerous. There are no fewer than 180 castles and ruins of the middle ages.

Mr Coxe reckons the population of the Grisons at 98,000.

| | |
|---|---|
| The Grey League contains - - | 54,000 souls. |
| League of God's House - - - | 29,000 |
| League of Ten Jurisdictions - - | 15,000 |
| | 98,000 |

In the year 1806, the population was 73,862, viz.

| | |
|---|---|
| Protestants - - - - - - - | 44,982 |
| Catholics - - - - - - - - - | 28,880 |
| | 73,862 |

Or they may be divided into

| | |
|---|---|
| Germans - - - - - - - - - | 28,000 |
| Those who speak the ancient Rhetian language - - - - | 36,065 |
| Italians - - - - - - - - - | 9,797 |
| Total population | 73,862 |

This number is exclusive of the provinces formerly subject to the Grisons. Se Coxe's *Travels in Switzerland*, vol. iii.; Ebel's *Manuel d'un Voyageur en Suisse*, passim; and Planta's *Account of the Romansh Language*, in the Philosophical Transactions for 1776, vol. lxvi. p. 129.

GRODNO, is a town of Poland, in Lithuania, and, with the exception of Wilna the capital, is the most important place in that province. It is now a frontier town on the Russian division of Poland. It is built upon an eminence which overlooks the river Niemen, which is here a broad, clear, and shallow stream. Grodno is a large and straggling place, and has the appearance of a town in decay. The few houses that are in good repair form a singular contrast with the wretched habitations, the falling houses, the ruined palaces, and the magnificent gateways, which are everywhere to be seen. Some remains of the old palace, in which the kings formerly resided during the diets, are still to be seen upon a hill of sand, rising abruptly from the river, and forming a part of the bank. The new palace is opposite to this hill. It was built, but never inhabited, by Augustus III. and became the temporary residence of Stanislaus Augustus after his abdication. It contains the apartments for the meeting of the diets. The late king of Poland established at Grodno a royal academy of physic for Lithuania, in which ten students are instructed in medicine, and twenty in surgery, and are lodged, boarded, and taught, at the royal expence. The physic garden contained 1500 exotic plants, when Mr Cox passed through the town in 1778. The principal manufactures here are cloth and camlets, linens and cottons, silk stuffs, embroidery, silk stockings, hats, lace, fire-arms, needles, cards, bleaching wax, and carriages. They were chiefly established by the king in 1776, and in 1778 they were carrying on in wooden sheds, built by Augustus III. for stables, which were converted into temporary working looms, and dwelling houses for the workmen. The establishment was subsequently removed to Lossona, a village near Grodno, where convenient buildings were erected at the public expence. The country furnishes a sufficient supply of wool, flax, hemp, beaver's hair, and wax, for the manufactories that require these articles; but the silk, cotton, iron, colours, gold and silver, for the embroidery, and the fine thread from Brussels, are all articles of import. Three thousand persons are employed in these manufactories, including those in the neighbouring villages who spin linen and worsted. Seventy foreigners direct the different branches, and the rest are natives. Grodno contains nine Catholic churches, and two Greek churches. The population consists of 3000 Christians, exclusive of those engaged in manufactures, and 1000 Jews. See Cox's *Travels in Poland, &c.* vol. 1. p. 220, 223.

GROINS. In our article CARPENTRY, we have already treated the subject of groins at some length. We proposed, under the present head, to have investigated the subject of *Domes*, from which we have made a reference; but we have found it necessary to include this subject under that of ROOFS, to which the reader is referred.

In the article CARPENTRY, we have mentioned the great improvement in the construction of brick groins, rising from rectangular piers, as made by Mr George Tapper. The following account of this improvement has been drawn up for our work by Mr John Narien.

If a square or rectangular area be covered with two vaults, penetrating each other at right angles, and forming two ridges which cross the area diagonally, and intersect each other at the common summit of the vaults, the arch thus formed is called a groined vault: the penetrating vaults may be either semicircular, or semi-elliptical, or one of them may be semicircular and the other semi-elliptical. The intersections of the circular or elliptical vaults, forming the ridges or groin angles, will be ellipses, because every oblique section of a cylinder or elliptical prism produces an elliptic curve, and the case will be the same when one of the vaults is circular, and the other elliptical; for if horizontal lines were drawn from points in the diameter or chord of the circular vault perpendicularly to that diameter, and cutting in different points a line drawn diagonally across the area, the ordinates drawn up to the ridge or groin angle from these points, will be respectively equal to the ordinates at the corresponding points under the circular vault, and consequently their ends will be in the periphery of an ellipse.

The four vaults or arches forming the groined vault, spring from the angles of four square abutment piers, and if the intended vault is to be built of stone, the courses in each arch respectively are laid upon the centering, in lines parallel to the axis of the arch they compose, in such a manner that the voussoirs of each arch meet the voussoirs of its adjacent arch at the groin angle, where the faces of the angular voussoir in each course are wrought in such a manner as to form the curve of the groin, which springs from the angle of the pier on which the arches stand. The upper surfaces of these angular voussoirs are also wrought, so that on both faces they may coincide with the other stones of the same course, by which means these surfaces meet in a ridge which is always perpendicular to the curve of the groin angle. When the intended vault is to be built of brick, the internal faces of the brick voussoirs in each course are cut away at the groin angle, to receive the wedge-like end of a brick in the adjacent arch in the same course, in order to bind the arches together more firmly: (See Plate CCLXXXIV. Fig. 1.) But as bricks have not, like wrought stones, the form of a frustrum of a wedge by which they may sustain themselves when arranged in the shape of an arch, their stability must depend upon the strength of the cement placed between them, which, uniting them into one mass, renders a structure of this kind a sort of vault hewn out of a rock.

From a consideration of the above mentioned mode of constructing groined vaults, it will be evident that the pressures, both vertical and lateral, of all the arches of which they are composed, are resisted and sustained by the mutual intersections of the courses of masonry at the groin angles; these intersections may be considered as squares upon the corners of the piers from which they spring, the side of the square being equal to the thickness of the course of voussoirs, so that the diagonal ribs of the vault form as it were two arches, which are kept in a state of equilibration, by the weight of the spandrils immediately over them, and serve as bases upon which the side arches with their spandrils, and all the superincumbent loading, ultimately rest; hence it will be evident that, if the weight of the arches, with their loading over them, were in a constant ratio to the weight necessary for keeping the ribs in a state of equilibration, the whole vault will be in equilibrio in all its parts. This, however, cannot be attained in practice, because the distances between the ribs at any part are never in proportion to the height of the spandrils over the ribs at those parts, and therefore the groined vaulting will always in some degree be defective in its equilibration; besides the disadvantage arising from the whole of the weight falling entirely upon the ribs, which receive no support from the voussoirs of the contiguous side arches, whose joints are all oblique to the directions of the ribs.

But as groined vaults are absolutely necessary in warehouses, and many other buildings, for the purpose of giving communication throughout the same in every direction, which cannot be obtained where waggon-head vaults are used and as there is a great saving of materials, resulting from the arches bearing on piers only, instead of parallel walls, it follows, that an improvement in their construction, which tends to bring them nearer to an equality in strength with the waggon-head vaulting, must be a great acquisition. This improvement has been lately made by Mr George Tappen, an architect of London, who, instead of the square piers hitherto used, has adopted octangular ones, (by which a considerable saving of room is made,) and has thrown stout ribs diagonally over the vault, whose breadths are equal to the sides of the octagons on which they stand. The side arches, which in brick-work are set four inches back from the face of the ribs, in order to save the trouble and expence of cutting the groin angles, are worked into, and rest upon these ribs. By this improved construction, the ribs form a much stronger support for the weight of the incumbent vault, and the loading above, than by the old method, as the following comparison will shew.

Since the force of the superincumbent weight has been found by experience to act chiefly in the direction of the groins, they require the greatest strength that can be given them; at the same time, the side arches should be made to throw as little weight as possible upon them, particularly about the summit of the vault, that their tendency to fracture towards the crown may be diminished as much as the nature of the case will admit. In the groined vaults hitherto constructed, where the groins spring from the extreme corners of the square piers, their section, taken perpendicular to their length, forms a square, (see *a*, Plate CCLXXXIV. Fig. 2.) having one of its angles turned towards the centre of the curve, and its side equal to the thickness of the arches; whereas in the new vault, the section taken in the same manner, forms a rectangle equal in breadth to the side of an octagon inscribed in the square pier, and of a depth which may exceed that of the old groin in any proportion, (see *b*, Fig. 2.) Now, the strength of an arch, in its different points, is measured by the greatest weight which it is able to carry on those points without breaking; that is, it is in a ratio compounded of the triplicate ratio of the secant of the angle of the curve's inclination to the horizon, in its various points, and the reciprocal simple ratio of the radius of curvature in the same points. But since the relative strength of arches is to be determined by comparing them in their weakest parts, (namely the crown,) the strength of any arch at the crown will be reciprocally as the radius of curvature at that point, since the angle of the curve's inclination to the horizon at that point is always 0° 0′; or reciprocally as the span of the arches, when the rise of them is the same, their thickness being supposed equal. From this it will be evident, that the strength of the diagonal ribs and groins will be directly as the areas of their sections and distances of the centres of gravity from the place where the fracture would end, and reciprocally as the spans of the arches: that is, if A represent the area of the section, G the distance of its centre of gravity, and S the span of the arch; then the strength of one arch to that of another will be as $\frac{A \cdot G}{S}$.

Let the side of the square pier be $= a$; then the thickness necessary for the side arches will be $= \frac{a}{4}$, which, consequently, will be the side of the square section of the groins in the old arch; its area, therefore, will be $= \frac{a^2}{16} = A$, and its half diagonal $= \frac{1}{2}\sqrt{\frac{a^2}{8}} = G$. The distance of the piers being $4.5\,a$, the span of the diagonal groins will be $= \sqrt{2 \times (4.5\,a)^2} = 6.364\,a = S$; we have therefore $\frac{A \cdot G}{S}$ $= \frac{\frac{a}{32}\sqrt{\frac{a^2}{8}}}{6.364}$ for the strength of the old groin.

The side of the square pier remaining still $= a$ in the new arch, the breadth of the rib $= \sqrt{2\,a^2} - a$, which is the side of an octagon inscribed within the pier, the thickness proper for the rib will be $= \frac{a}{3}$: then will $A = \frac{a^2\sqrt{2} - a^2}{3}$; $G = \frac{a}{6}$; and $S = 5.364\,a + \sqrt{2\,a^2}$; consequently $\frac{A \cdot G}{S} = \frac{a^2\sqrt{2} - a^2}{122.004}$, the strength of the new rib.

If we assume $a = 4$ feet 8 inches, (the dimensions assigned by Mr Alexander to the piers of the groined vaults at the London dock tobacco warehouses.) the strength of the old groins will be to that of the new ribs as 5.44 to 10 64, which is nearly 2 to 1 in favour of the new construction; and this will be the case while the same proportions are preserved, whatever may be the extent of the arch.

If the side arches, with their spandrils, and the loading on the floor above, be cut by parallel vertical planes, (as at S, Fig. 2) the sections will be to each other as their chords *c d* nearly; which being less in the new vault than in the old, on account of the greater breadth of the ribs, the weight incumbent on those ribs (which always tends to destroy their equilibrium) is just so much less in the former than in the latter, and consequently their tendency to fracture is diminished in the same proportion.

It may not be improper to observe, that Dr Hutton recommends the stones of the wall, or spandril over the extrados of the voussoirs of an arch, to be bonded into the stones of the pier, and with one another; because the pier will then carry part of their weight, and thereby oppose a greater power of resistance to the thrust of the arch. For the same reason, it would be equally advisable, in the new method of building groined vaults, to carry up at the same time the diagonal ribs, side arches, and spandrils, well bonding the whole together into one solid mass; which will render vaults built in this manner a valuable acquisition in warehouses and other large buildings, where the greatest weights are to be sustained.

GRONINGEN, a town in Holland, and capital of the province of the same name. It is intersected by the river Hunes, which passes through it in a northerly direction to the sea. The town is large, rich, strong, and populous, and is adorned with many excellent buildings. It is nearly round, and is surrounded with good ramparts, a wall, and ditches, and has a citadel. Its university was founded in 1614, and endowed with the revenues of several monasteries. The harbour can contain many vessels, which enter it by a canal about nine miles from the sea. It carries on a considerable trade in butter, horses, and horned cattle. There are some breweries in the town.

GROSE, Francis, a celebrated antiquarian, was born in 1731, and was the son of a jeweller at Richmond, who died in the year 1769, and left his son an independent fortune. He entered into the Surrey militia, and was appointed adjutant and paymaster; and such was his love of dissipation, that he soon squandered away the fortune which his father had accumulated. The distress to which he was now reduced, compelled him to have recourse to his talents; and having a fine taste for drawing, he began to collect materials for his *Views of Antiquities in England and Wales*, a work which he began to publish in numbers in 1773, and which was completed in 1776. Other two volumes, including Guernsey and Jersey, were completed in 1787. The success of this work induced him to embark more deeply as an author. In the summer of 1789, he made a tour through Scotland; and in 1790, he began to publish in numbers, his *Antiquities of Scotland*, which were completed in two volumes 4to. In the year 1791, Mr Grose set out for Ireland, with the view of collecting materials for an account of the antiquities of that country; but soon after his arrival at Dublin, he was seized with an apoplectic fit, of which he died, on the 6th of May 1791, about the 60th year of his age. Mr Grose was remarkable for his good humour, conviviality, and friendship. He was extremely corpulent, and altogether singular in his external appearance. A likeness of him, at full length, is given in his Olio, published after his death.

The following is a list of his works: 1. The Antiquities of England and Wales, 8 vols. 4to. and 8vo. 2. The Antiquities of Scotland, 2 vols. 4to. and 8vo. 3. The Antiquities of Ireland, 2 vols. 4to. and 8vo. 4. A Treatise on Ancient Armour and Weapons, 4to, 1785. 5. A Classical Dictionary of the Vulgar Tongue, 8 vols. 1785. 6. Military Antiquities; being a History of the English Army from the Conquest to the present time, 2 vols. 4to, 1786, 1788. 7. The History of Dover Castle, by the Rev. William Daniell, 4to, 1786. 8. A Provincial Glossary, with a Collection of local Proverbs and popular Superstitions, 8vo, 1788. 9. Rules for drawing Caricatures, 8vo, 1788. 10. Supplement to the Treatise on Ancient Armour and Weapons, 4to, 1789. 11. A Guide to Health, Beauty, Honour, and Riches; being a collection of humorous Advertisements, pointing out the means to obtain those blessings; with a suitable introductory Preface, 8vo. 12. The Olio; being a Collection of Essays, in 8vo, 1793.

GROTIUS, Hugo, one of the most profound and enlightened scholars, and one of the most remarkable men of his age, was born at Delft in the United Netherlands, on the 10th of April 1583. The name in Dutch is *De Groot*, or *the Great*; and as it had for many ages been the patronymick of one branch of his ancestors, the circumstances which led to its adoption are unknown. But few families have better merited such a distinction, if greatness be estimated not by external rank and honour, but by those intellectual and moral endowments which far surpass in value all the gifts of fortune. The family of Grotius had been illustrious at Delft for four centuries, and he himself in the estimation of his own age and of posterity, pre-eminently merited the surname of *Great* among the *great*. He did not descend, however, in the uninterrupted male line from that family; for it is related, that about the year 1430, Dederic de Groot, burgomaster of Delft, and a highly distinguished member of the family, had an only child, a daughter named Eremgard, whom he left a wealthy heiress. This young lady was sought in marriage by Cornelius Cornetz, who sprung from that branch of the noble family of Cornetz, which, under the Dukes of Burgundy, had emigrated from France into Holland. The lady favoured his addresses, but, under this stipulation, that should there be any children of the marriage, they should take the name of her and her ancestors, *De Groot*. The first who, in conformity to this agreement, bore her name, was Hugh, grandson of Dederic, and grandfather of the subject of this article. One of the sons of this Hugh was Cornelius de Groot, born in Delft in 1544. After acquiring much learning at his native place, he prosecuted his studies, literary and mathematical, with great ardour at Louvain and Paris. He delighted in the philosophy of Plato. He then applied himself to the civil law at Orleans, and on his return to Delft, betook himself to the bar, and afterwards filled several important offices. In 1575 he was appointed professor of philosophy in the university of Leyden, which dates its origin from about that time, and which has since been so celebrated in the republic of letters. He afterwards taught the civil law in that seminary, and evinced his preference for the quiet pursuits of learning, by refusing a seat in the great council of the States, though that appointment was repeatedly pressed on his acceptance. He died without issue in 1601. Hugh De Groot had another son, John, who also studied law. He was appointed burgomaster of Delft, and afterwards curator of the university of Leyden. He was an elegant scholar and a poet. But his chief claim to the remembrance of posterity is, that he was the father of our Hugo Grotius, to whom it is now proper to direct our attention.

This illustrious man was born, as we already stated, at Delft, in 1583. His mother's name was Alide Overschie, and the family to which she belonged was of some note. Endued by nature with admirable talents, he enjoyed from his infancy the advantage of an excellent education. When he was only seven years of age, he was placed under the tuition of masters, with whom he made such extraordinary progress, that before he had completed his ninth year he composed verses which obtained the approbation of the learned. At twelve he was so great a proficient in the knowledge of the classics, and of *belles lettres*, that he was qualified to pursue his studies at the university. He was accordingly sent in 1595 from Delft to Leyden, where he spent three years in the study of mathematics, philosophy, theology, and law, and excelled in the knowledge of each of these sciences. He was only fifteen years old when he wrote a commentary on a very difficult Latin poet, Marcianus Capella. The celebrated statesman, John Barnevelt, attorney-general of the republic of Holland, having been, in 1598, appointed ambassador to France, the young Grotius accompanied him thither. Henry IV. who then reigned in France, gave him most gratifying marks of his esteem. The monarch presented him with a gold chain, and a portrait of himself; and it is said that he was so highly pleased with such attention, that he caused his own portrait to be engraved, adorned with these tokens of royal favour. While he remained in France, he obtained the degree of Doctor of Law at the early age of sixteen.

On his return to Holland, Grotius, in compliance with his father's desire, entered on the profession of law; and at the age of seventeen, he began to plead with distinguished ability and success. He retained his fondness, however, for classical and literary pursuits, and continued to prosecute his general studies with ardour in those intervals of leisure which his laborious profession allowed, and which supplied the place of recreation, chiefly by affording a change of employment. When he was in his 24th year, he was appointed attorney-general of Holland, Zealand, and West Friezland, and filled his high office with such talents and integrity, that the salary attached to it was augmented.

In 1613 he removed to Rotterdam, to engage in the duty of pensionary, or chief magistrate of that city, as successor of the recently deceased Elias Barnevelt, brother of John, his early patron and friend. At this time, religious controversy ran high in the United Provinces between the Calvinists, or Gomarists as they have been called, from Francis Gomar of Bruges, and the Armenians, especially with respect to grace and predestination. Grotius, amidst the heat of the contending parties, conducted himself with such prudence and moderation, as to retain for a considerable time the respect of both. He was also admitted into the assembly of the states of Holland; and as he had written in defence of the right of the Dutch to trade with India, he was sent to England, to adjust the differences which had arisen between the merchants of the two countries. He succeeded in the object of his mission, and received marks of regard from James I. At his return home, he found the United Provinces divided and distracted by quarrels about religion; and while he had the affliction to see that true patriot and able politician, John Barnevelt, sacrificed to a faction, under the pretence of treason and heresy, to gratify its own ambitious projects, Grotius himself most narrowly escaped sharing his melancholy fate. Barnevelt was tried by twenty-six commissioners deputed from the Seven Provinces, and, in terms of the sentence of this cruel tribunal, was beheaded in 1619. Grotius, who had been warmly attached to him, and who was suspected, by the bigots of the day, of favouring the Armenians, was involved in his disgrace. He was arrested in August 1618, and in May following was condemned to perpetual imprisonment, and to have all his property confiscated. He was strictly confined in the castle of Louvestein, near Gorcum. "Here he remained," says Dumourier, "without any other consolation than the company of his wife, and of books which his friends were permitted to send to him. A large trunk was usually sent filled with books, which he returned after having devoured them, (*après les* *avoir devorés*,) and it was during this imprisonment that he translated Stobœus. But his confinement lasted only about two years, as he was happily delivered from it by the address of his wife, Mary Reygelsberg.* She, having remarked that his guards (tired with frequently searching the great chest filled with linen or books, that passed between the prison and Gorcum) allowed it at length to be transmitted without opening it, advised her husband to place himself in it, after having made holes with a wimble in the part of it over his face, to allow him to breathe. He entered into the scheme, and was thus carried to the house of one of his friends at Gorcum, whence he went to Antwerp by the ordinary conveyance, after having passed through the market-place at Gorcum, disguised as a mason with a rule in his hand. His wife, who had so dexterously managed the affair, pretended that her husband was much indisposed, in order to afford time for his escape; but when she supposed him to be in a place of safety, she told the guards that the bird was flown. It was at first intended to prosecute her, with a view of having her confined in her husband's stead; but she was liberated by a majority of votes, and she was universally praised for having restored her husband to freedom. This took place in March 1621." Dumourier *Memoires de Hollande*. Grotius, thus happily delivered, secretly left Antwerp in the following month, and repaired to France, where he experienced powerful protection, and was introduced to Louis XIII. who bestowed on him a pension of 3000 livres, which he enjoyed for about ten years. Prince Maurice, the enemy of Barnevelt, and persecutor of Grotius, died in 1625; and it is a circumstance highly honourable to Grotius, that in his History of the Netherlands, from the departure of Philip II. till 1608, which was not published till after the author's death, he relates the splendid achievements of this prince with the utmost fidelity, and without alluding to the harsh treatment which he had suffered from him. The brother of Maurice, Prince Henry Frederic, entertained the most friendly disposition towards Grotius, and would gladly have recalled him, but was deterred by the jealousy of his political opponents, which still existed with unabated force.

Many attempts were in the mean time made, but, happily for the best interests of learning and humanity, without success, to excite prejudice against him in the breast of his powerful protector Louis. That prince was not to be influenced by such unworthy efforts; but, on the contrary, his respect for Grotius increased, by observing the unabated love which the illustrious exile bore towards his ungrateful country. He employed much of his time while in France in reading and composition, and increased the resentment of his enemies who then prevailed in Holland, by his admirable defence of the deposed magistrates.

In 1631, his pension from the French court was withdrawn, whether from motives of public economy, or from ministerial pique, or from what other cause, cannot be ascertained. He soon after ventured to return to Holland, confiding in the friendship of Prince Henry Frederic. But, through the malice of his enemies, he was condemned anew to perpetual exile. Finding himself cruelly compelled to leave his native land, which he still fondly loved, he repaired to Hamburgh, where he received the most gratifying offers of protection from the kings of Denmark, Poland, and Spain, accompanied with solicitations from each, that he would attach himself to his court. He preferred, however, the patronage of Gustavus Adolphus, king of Sweden, whose death, in 1632, obliged him for some time to remain unemployed in Hamburgh. Queen Christina fulfilled the wishes and intentions of her predecessor; and in 1634, appointed Grotius one of her counsellors. She soon after nominated him to be her ambassador at the court of France. This new diplomatic appointment displeased Cardinal Richelieu, then prime minister of Louis XIII. and he used his influence with Oxenstern, the chancellor of Sweden, to have him recalled. Grotius, who had remained in retirement at St Denis till the ulterior pleasure of the Swedish court should be known, made his formal entry into Paris as Swedish ambassador in March 1635. After having spent eleven years in France, he was, in consequence of his own request, recalled, and having occasion to pass through Holland in his way to Sweden, he was received at Amsterdam with every mark of respect and honour; for many of his enemies had retired, or were dead, and several of his friends were restored to offices of public trust. The account which he gave to the Queen of Sweden of the affairs connected with his embassy, proved highly satisfactory; and anxious as he was to retire from public life, she would have gladly retained him in her councils; but the jealousies of her courtiers inducing him to persist in his desire, she at length consented. She made him, when on the eve of his departure, a present of twelve thousand rix-dollars. Stress of weather driving the vessel in which he embarked for Holland upon the coast of Pomerania, he was put ashore in a bad state of health, intending to finish his journey by land. He was unable to proceed farther than Rostock. Calumnies, with regard to the soundness of the religious principles of Grotius, and the state of his mind at his death, were officiously published by his enemies; but they are satisfactorily confuted by John Questorpius, professor of theology, and minister of Rostock. This learned and pious man wrote a letter, which is still extant, giving a pleasing account of the chearful resignation and Christian piety by which the close of his valuable life was characterized. He expired at Rostock, on the 28th of August 1645, in the 63d year of his age. The remains of this great and good man were embalmed, and removed to Delft, where they were committed to the sepulchre of his ancestors. His wife appears to have survived him. He left three sons and a daughter. The eldest son Cornelius, who wrote elegant Latin verses, was for some time employed by Oxenstern in Sweden. The second, Dederic, was aide-de-camp to Duke Bernard of Weimar, and was assassinated in a tavern by his valet. The youngest, Peter, was appointed by the Elector Palatine to be his resident with the states general; and, by the favour of the De Wits, he was made pensionary of Amsterdam. After having been employed in different political embassies for Holland, he was tried for alleged offences against the state, and was acquitted. He died in retirement at the age of seventy. Cornelia, the daughter of Grotius, was married to M. de Mouthas, who served with eclat in Holland; but being involved in the fall of the De Wits, he quitted that country in 1672.

The multitude of works which Grotius left behind him on various subjects, prove him to have been an universal and profound scholar, and a man of the most indefatigable industry. It is not without astonishment that we contemplate the literary labours of one, whose private misfortunes and public duties might have been supposed to leave him little inclination, and less leisure, for the calm pursuits of philosophy and science. His mind was amply stored with the treasures of ancient and modern learning, and his excellent memory enabled him to retain and employ, as occasion might require, the knowledge which he derived

* Dumourier writes her name Reygelsberg, as in the text; but in a marginal note in Bayle's Dictionary, she is called Reygersbergen.

from his books. It is indeed related of him by Borreman, in proof of his wonderful memory, though we must be permitted to doubt the accuracy of the anecdote, that Grotius having been present at the review of a regiment, recollected the name of every individual belonging to it.

It would be tedious to give a catalogue of the works which are known to have proceeded from his pen, most of which were published during the life of the author, as they amount to seventy-four or seventy-five. As his writings, however, exercised a powerful influence, not only over his contemporaries, but have continued, and still continue, to influence the policy of nations, and the opinions of scholars and philosophers throughout the civilized world, we shall mention the names of some of the most remarkable, and add a few occasional reflections on their value. Considering him, then, as an author, we may, for the sake of arrangement, notice some of those compositions which exhibit him respectively as a scholar and poet, a patriot, a philosopher, a philanthropist, and a theologian. It is to be premised, that his works were generally written in the Latin language, which in his time, and for ages after, formed the chief medium of communication among the learned of all the countries of Europe.

In viewing Grotius as a scholar and a poet, we may mention the following works:

1. *Poemata nonnulla, seu Characteris Pontificis Romani*, &c. &c. 4to, 1599.

2. *Marciani, M. F. Capellæ Satyricon, seu de Nuptiis Philologiæ et Mercurii, libri duo emendati et notis illustrati*, 8vo, 1600. This learned publication, from so young an author as Grotius, was among the first things that brought him into notice, and gave a most auspicious promise of his future greatness.

3. *Mirabilium anni* 1600, *quæ Belgas spectant*, &c.; a poem in 4to.

4. *Adamus Exul*, tragædia, 8vo, 1601. This work was printed when the author was only eighteen, and about seven years before the birth of Milton. Whether or not this tragedy may have suggested the idea of *Paradise Lost*, or how far he, Milton, may have availed himself of it, we have not at present the means of ascertaining. But the choice of this subject by two such eminent contemporaries, is an interesting coincidence in the history of literature.

5. *Christus patiens*, tragædia, 8vo, 1608. This tragedy was translated into English by George Sandys, with notes, in 1640. A German writer used it as a model for the illustration of the rules of tragedy; and Curpzovius, Professor of Poetry at Wittemberg, made it the theme of some of his lectures.

6. *Commendatio Annuli*, (a poem) 4to, 1609. 7. *Lucani Pharsalia*, cum notis, 4to, 1614. 8. *Exerpta ex Tragædiis et Comœdiis Græcis*, &c.

In the biographical sketch, we have had occasion to mention the ardent love of country which characterized Grotius, amidst all the sufferings and varieties of his life; and we noticed two of his works relating to his native land, the one of a historical, the other of a commercial nature. The title of the latter of these, and of the answer to it, are curious, and particularly when we consider them in connection with the political events and speculations which have marked the close of the eighteenth, and the opening of the nineteenth century, both on this and the other side of the Atlantic. It is called *Mare Liberum, seu de jure quod Batavis competit, aut Indica commercia*, 8vo, 1609. It was at first printed anonymously, was then translated into Dutch, and passed through many editions. After the lapse of some years it was answered by John Seldon, in a composition entitled *Mare clausum, seu de dominio maris*, Lond. 1635. To this attack, Grotius, in so far as we have been able to discover, made no reply. Grotius published in 4to, A. D. 1610, his work *De Antiquitate Reipublicæ Bataviæ*. Also, a Discourse pronounced in the Senate of Amsterdam, upon the views of the States of Holland respecting the Reformed Religion. In the Dutch language, 4to, 1616.

But it behoves us now to speak of the great work upon which the fame of Grotius chiefly rests, which exhibits him as a citizen of the world, and which forms the beginning of a great era in the history of political philosophy. The work to which we allude was written in France, at the instigation of his friend Peireskius, and printed at Paris, in 4to, in 1625, entitled *De Jure Belli et Pacis*. The President Jean Jacques de Mesmes gave him the use of his country house Balagni, that he might have leisure and retirement for the composition of this work. The author dedicated it to Louis XIII. and he quickly attained by it a splendid height of popularity and fame. It was revised and improved by Grotius, and translated into many languages. Under this title he has attempted to give a complete system of natural law, and to evolve from the mass of precedents and particular statutes, which constituted the chief study of the lawyers of his time, many of those general maxims which should enter into the principles of legislation, and regulate inter-national transactions, as well as to point out their foundation and sanctions in the nature of man, and in the constitution of human society. His work partakes, in some respects, of the prejudices of the age in which it was written, and, particularly, of an overstrained reverence for the institutions of the Roman law. It is also overloaded with quotations and authorities from classical writers, from the Mosaic law, from other parts of scripture, and from various writers sacred and profane, by which the mind of the reader is often perplexed rather than enlightened; and the diffuseness of the notes forms a curious contrast to the brevity and obscurity of the text. Puffendorff, for whom a professorship was formed at Heidelberg, for the express purpose of extending the knowledge of the doctrines of Grotius, is deemed the most eminent of his disciples and commentators. These doctrines have been since taught almost to our own day, in the most celebrated universities of Europe, and, in the opinion of respectable judges, form the foundation of the ethical and political philosophy of the present times. Bayle has justly remarked, that Grotius must be deemed particularly fortunate as an author; and that, fifty years after his death, this work obtained for him an honour, which was not bestowed upon the ancients till after many ages, namely, that he appeared in it *cum commentariis variorum*.

We have space only farther to mention, that, besides several treatises connected with religion and the controversies of the day, Grotius distinguished himself by a popular and a philosophical work in defence of Christianity. The first of these was entitled, Proofs of the True Religion. It was written in Dutch verse, with the benevolent designs of furnishing innocent and useful employment to the minds of his sea-faring countrymen in long and tedious voyages; and of enabling them to maintain their stedfastness in their own faith, and, as opportunities might occur, to explain and recommend it to the foreigners with whom they might have intercourse. The other work to which we have alluded, is the celebrated treatise *De Veritate Religionis Christianæ*, which was published at Paris in 1639, and dedicated to his friend Bignonius. The plan of this work is comprehensive, the style frequently obscure, and the notes unnecessarily copious and minute. Yet, as it was among the first works of the kind which were published, and as it contained much new and excellent argument and illustration, it has been translated into all the European languages, referred to in most works on the same subject, and preserves its estimation as a standard work on theology at the present day. (*l.*)

GROTTO, is a subterraneous fissure or opening in the earth, generally adorned by calcareous incrustations, which produce a brilliant effect when illuminated by torches.

Mountainous and volcanic countries, or those regions which are partitioned into many islands, more frequently exhibit grottos, caverns, or fissures, than low or level grounds. They are also common in places subject to earthquakes, and have the greatest extent and intricacy in countries where huge masses of limestone abound.

The most celebrated grotto for beauty, size and, magnificence, is that of Antiparos, an island of the Mediterranean, already described in the previous part of this work; and that which is reputed next to it is of recent discovery in the island of Skye, among the Hebrides of Scotland. It had been long known to the islanders, that the mouth of a cavern, called *Slochd Altriman*, or the *Nursling Cave*, opened among the cliffs overhanging the sea on the south-west shore, and that a particular tradition was annexed to its history. But none ventured to explore its recesses, until, in the year 1808, the masculine intrepidity of a lady, Mrs Gillespie, exposed to more timid adventurers what has been called one of the most remarkable phenomena, which exists in the structure of the earth.

This cave comes under the particular description of a grotto; for, it may be observed, that a cave and a cavern, between which some authors even make a distinction, properly implies a subterraneous vacuity without incrustations. The land above *Slochd Altriman* is of moderate height; but, from the shore consisting entirely of perpendicular rocks, the entrance can be reached on foot only at low water, and then with particular difficulty. When the tide is up, however, a boat can easily approach it, unless the wind should render such an attempt dangerous from sunken rocks, and dislocations of stony masses from the cliffs. The grand access to the cave is formed by two immense walls of free stone, separated thirty feet asunder, rising above 100 feet in perpendicular height, and stretching out in a straight line from the shore. Here the tide flows in about 400 feet; but, at low water, the bottom is rough, and covered with slippery weeds. These obstructions being surmounted, a magnificent rugged arch, of a Gothic form, is presented to the spectator, and on one side an inferior cave with many lateral crevices. This great aperture is embellished with innumerable dark green stalactites of various sizes; some descending to the ground, and forming pillars overgrown with moss, which, with the intermixture of vivid foliage, brown heath, and wild flowers, produces an interesting combination. Close to the entrance of this grotto, there is, as it were cut out of the stone, a small fountain of pure water, surrounded by rocky pillars, and the water collected in the cistern is derived from the exudation of the rock above. A passage about nine feet broad, and from fifteen to twenty in height, conducts the visitor almost on a perfect level for twenty yards, when a steep ascent for 55 feet leads up a bank of earth, sand, and small broken whinstone; another acclivity now commences, more difficult to overcome, of irregular surface, resembling a solid cascade, or frozen snow, and sparkling with crystallizations. Advancing a few yards, the principal entrance to the interior grotto is gained, eight feet broad, and twelve in height, universally white as marble, and variously decorated with beautiful incrustations. Thousands of icicles of pure white spar are suspended from the roof like the festoons of a curtain, giving the whole a finished appearance. The breadth, on proceeding still farther, enlarges to ten feet, and the height to forty, while the white marble spar continues rough and uneven; and it is only after traversing thirty-five feet of this gallery, that the proper excavation, which has been denominated the *Spar Cave*, is reached. It consists of a circular vacuity about twenty feet in diameter, with a lofty roof, and a pool at the bottom, contained in a marble cistern. But the whole is said to exhibit the most brilliant spectacle which imagination can conceive. The sparry concretions are innumerable, and in every variety of form; while the lights, by which the spectator examines them, are reflected from a thousand glittering points. Many of the surrounding objects, formed by the calcareous depositions, are compared to animate and inanimate substances of various descriptions. To the right is the resemblance of a monk, as if kneeling on a cushion, with uplifted hands, and large as life. Behind it appear several semblances of busts; and at a distance are seen the images of various animals, together with an exact representation of a fleece. But among the whole, the monk excites the greatest attention. The head is bare, after the monastic fashion; the face is supposed to be distinct; the shoulders are in just proportion; and the drapery of the robe enveloping the body is alike beautiful and correct. Figures of vegetables are every where formed; and numerous columns, some apparently supported by distorted beings, seem to sustain the roof, which resembles a pure white cloud suspended in the air. Portions of it, however, descend in stalactites; which, together with the crystals in the interstices of the columns, emit fine coruscations from the lights below.

Another rugged declivity, similar to that which conducted the spectator to the cave, leads down to the pool, which is sixty-five feet in circuit, five feet deep, and of cooler temperature than the external atmosphere. It resembles a large marble bath of pellucid water, the bottom and sides being of the purest white. It occupies so much of the base of the grotto, that a person cannot walk round it. On its margin the spectator finds himself standing in a magnificent apartment, wholly consisting of the most brilliant spar glittering on all sides, and emitting myriads of rays, which are reflected from the bottom of the pool. In some grottos and caverns of other countries, there is a constant supply of water, which is generally discharged by a stream running towards the entrance; but here there is no visible outlet, and the quantity of water in this reservoir is not observed to decrease. Crossing the pool on a plank, a gallery of great height, but only three feet wide, is found, which leads to farther passages imperfectly explored. Its entrance is formed by two large columns of pure spar: that on the left of rustic conformation, six feet in circumference, and sixteen high; but that on the right rather resembles a work of art. It is of more surprising structure, and more elegant appearance, than any of the figures which the spar of this grotto has assumed. The shaft is twenty feet in length, nearly cylindrical, and its thickness in general about two feet and a half. It stands on a regular circular base rising from the floor, and projecting about twelve inches round its circumference. A series of sections seems to constitute the whole column, each twenty-two inches in length, and divisible into two distinct portions; the upper one being a crystallized mass of stalactites, while, in its general aspect, the under part resembles the foliated carvings of the Corinthian or Composite capital inverted. On more minute inspection, this division is found to display the most methodical arrangement of structure, in the formation and insertion of the foliage of sparry concretion; and the interstices of the leaves are of such dimensions, as to admit of complete inspection of the interior of the column, which proves a combination of the same foliated incrustations as the exterior. Passing by these pillars, the width of the gallery is somewhat enlarged, the sides still exposing elegant and numberless crystals, emitting a dazzling lustre. The floor also is of white marble, but of more singular conformation than in any other part of the cavity. Part of it rising from the rest resembles a piece of lace, and consists of many concretions on one side, while the other is quite smooth, and entirely covered with shining crystallizations, the waved interstices of which are full of water. These beautiful productions abruptly cease at the distance of about 250 feet from the mouth of the cave, and the bare black rock is exposed. Although farther recesses exist, they have not yet been explored.

Several singularities regarding this remarkable grotto being peculiarly interesting, ought not to be overlooked. Its formation is concluded to have resulted from the separation of immense dykes of whinstone, while freestone constitutes both the floor and the roof. Although no considerable stratum of limestone is seen in the neighbourhood, there is a prodigious accumulation of spar entirely calcareous within. The crystallizations are of the most complete kind, free from every imperfection, and white and beautiful. Water is constantly exuding from the whole roof; and it is likewise universally suffused over the incrusted surface of the spar, which is always moist to the touch. But this humidity augments the brilliancy of the coruscations, and is the source of the water contained in the marble cistern. The endless variety in which the sparry incrustations appear, is one of the greatest ornaments of the grotto; and the infinite combinations and modifications of it are alike brilliant and interesting. Sometimes it is disposed in foliage or flowers; sometimes in busts or columns; and the interior, of tubulated stalactites, is studded with innumerable crystals converging towards the centre. It may seem idle to speak of traditions of the ninth century, but we shall only observe in illustration of the name *Slochd Altriman* or the *Nursling Cave*, that it is said to have afforded refuge to a youthful female, who had become the victim of a feud which estranged the parents of her and her lover, the young chief of Colonsay. Separated from him, she was delivered of a son, who was carried to *Slochd Altriman*, whither his mother retired to nurse his infancy; and thence the name of Nursling Cave.

On the 17th of March 1775, the Rev. Mr Newnham, a young clergyman of Bristol cathedral, accompanied by a gentleman and two ladies, went to visit a chasm in the ground called Penpark Hole, about three miles from that city. Wishing to sound its depth with a line, he advanced a short way into the upper part of the opening declivity, which is not steep, in order to give it a freer cast, and, for greater security, held by the twig of a tree, spreading across the chasm. Unhappily, in accomplishing this, his feet slipped, owing to the humidity of the earth, and he was precipitated headlong into a frightful abyss before the eyes of his terrified companions. An accident so distressing, gave birth to many speculations respecting the caverns where it had happened, particularly as the body of the sufferer was long the object of a fruitless search; but at last some hardy adventurers having resolved on descending, discovered a great accumulation of water at the bottom, and a stone thrown down being interrupted in its fall, disclosed the spot where the body still floated, 39 days after the catastrophe. It is difficult to explain the figure of this, or indeed of any other cavern, without drawings; therefore we shall briefly observe, that the access to Penpark Hole is by two separate chasms in the ground, leading by a declivity to the interior. After passing different lateral vacuities, one of which has a spacious vaulted roof, the adventurer reaches the most extensive recess, branching into an oblong irregular space, 225 feet long, by 123 in width. Below it are other recesses, and the bottom of the whole, which, if we rightly understand the description, is more than 200 feet from the surface of the earth, is covered with water, varying in depth from 6 to 50 feet, but clear, and good, and free from any peculiarities. All the cavities are of extremely irregular formation, in general presenting a rocky surface or sparry incrustations, and the floor is described as in some places to consist of "a kind of white stone, enamelled with lead ore." The subterraneous communication between the external mouths is extremely narrow, and was first explored by Mr White, a land-surveyor, who, with much hazard and difficulty, forced his way through, by crawling on his belly. But even now, should a stone be displaced in the undertaking, the adventurer would inevitably be buried alive. Penpark Hole was visited in 1669 by Captain Sturmey, and in 1682 by Captain Collins. The former was accompanied by a miner, who, penetrating one of the galleries to a considerable distance, exclaimed that he had found a rich mine; but his joy was suddenly converted to astonishment, for he returned affrighted by the sight, as he said, of an evil spirit. No inducement could prevail on him to revisit the place, and Captain Sturmey himself sickened four days after and died. In consequence of the accident above related, it was more particularly examined by several individuals; but more minutely by Mr Catcott and Mr White, the latter of whom has drawn a section of it.

Great Britain abounds with caverns, and especially the county of Derby. Here there are no less than 28 of some celebrity, and some of lesser note. Several have already been alluded to in our notice of that county, as that stupendous recess, now converted from a rude and coarse appellation, to the Devil's Cave, or Peak Cavern, Elden Hole, and Pool's Hole, whence we shall restrict our observations to an abstract of Sir Richard Sullivans's adventure in the Three Mile Cavern. This is an immense vacuity that has partly been effected by art, and which receives its name from its supposed extent. The descent is accomplished with much difficulty for 420 feet, and introduces the spectator to two or three lofty caverns, beautifully enamelled with spar. "Penetrating still farther," Sir Richard says, "we forced our way with infinite struggles, through a narrow space between two rocks, and thence getting on our hands and knees, were, for the full distance of a mile, obliged to crawl, without ever daring to lift up our heads, the passage being both low and craggy; and as it was likewise filled with mud, dirt, and a multitude of bits of rock, our progress was painful indeed; we still, however, hoped for something better. On we accordingly proceeded, till a dreadful noise rumbling along the horrible crevices of the cave, gave us to understand we were near a river. To this then we hurried; but description is inadequate to any thing like a representation of the scene; a vast ocean seemed roaring in upon us; in some places bursting with inconceivable impetuosity; and at others falling through dreadful chasms, burst into shaggy forms to give it vent." It appears that this subterraneous stream is deep, and has a long course; but whether it is absorbed in the earth, or finds a passage to the surface, is not explained. After having underwent many dangers and difficulties, not unattended with personal injury, the author concludes his narrative in these words: "Altogether, the depth we had descended was about 140 fathoms, or 980 feet, and the length about three miles, according to the miners' calculation. Neither at this distance were we at the end; a passage still continued; but so filled with water, and so full of peril, that the miners themselves were averse to further trial." Possibly the number and size of British grottos and caverns, exceed those within the same bounds of any other country with which we are acquainted; nor are we aware that any spacious recess, (with the exception of the cave in Kentucky,) opening directly from the earth, has been penetrated 2250 feet, as the Devil's Cave of Derbyshire.

In the limestone country of Virginia in North America, are several caverns of some extent, among which the most celebrated is Madison's cave, on the north side of the Blue Ridge. Its entrance is about two-thirds high in a moderately elevated hill, into which it extends about 300 feet, branching out into subordinate caverns, sometimes ascending a little, but more generally descending, and at length terminates at different places in two basins of water of unknown dimensions, that are never turbid. The vault of this cave is of solid limestone, from 20 to 40 or 50 feet high, through which water perpetually percolates; and trickling down its sides, has encrusted them with elegant drapery, or dripping from the top, generates conical stalactites both above and below.

Another cave, about 8 or 9 miles long, and with many branches, has lately been discovered in Kentucky. It is covered with stalactites: and a very remarkable mummy was found within it at a considerable distance from its mouth. See Kentucky, where we propose to give a full account of this interesting cavern.

Besides those curious excavations on the western coast of the Indian peninsula, some interesting caverns occur in that great range of mountains, which traversing Cochin China, penetrates the neighbouring countries. The inhabitants retreat thither, or conceal their effects in them during the time of war, and they are also kept concealed to avoid the expensive visits of the great men of the country. A naturalist, the late historian of these regions, affirms, would here find ample scope for observation: the caverns are full of petrifactions and crystallizations of various colours: immense halls are formed, wherein may be seen the resemblance of altars or thrones; and quantities of fruits appear ready to drop from their trees. One most remarkable grotto traverses a mountain throughout: its entrance and its exit being terminated by two fertile plains. The bottom is covered with water, which may be navigated by vessels; and the roof, which is very lofty in some places, decreases elsewhere to 8 or 10 feet. There is another in the same chain of mountains of vast extent, but abounding in deleterious exhalations; and the water of a canal covering its bottom is dangerous to be drank. No one has hitherto ventured to explore its most distant extremities.

In various parts of Italy, we find several famous grottos, though less celebrated for their extent than from some other peculiarities; and although known by the name of grottos, no crystallizations are seen in some of them. In Naples there is a spacious cavity, called *Grotto dei Funaioli*, or the Rope Makers' Grotto, because its entrance has long been devoted to this useful purpose. The roof exhibits a rent, said to be the effects of lightning, and in other respects presents a menacing but imposing aspect, though the inhabitants carry on their operations in the most perfect confidence.

The grotto of Pausilippo near Naples, is a great excavation, partly artificial, penetrating the mountain of that name 2316 feet. It is 89 feet high in the most lofty part, 24 where lowest, and about 22 in breadth, traversing volcanic tufa. The date of its formation is unknown; but in modern times, Don John of Arragon, Viceroy of Naples, and Peter of Toledo, under Charles V. brought it to its present state, and now it serves for an ordinary, though disagreeable road from the city, with a glimmering light from two apertures above.

In the side of a hill, beside the lake Agnano, in Italy, there is an artificial excavation, unskilfully executed, called the *Grotto del Cane*. It is of limited dimensions, being only twelve feet deep, four broad, and nine in height at the entrance, but always decreasing as it recedes. The celebrity of this grotto, which had long been known, is owing to pestilential exhalations arising from the earth; and it receives its name from the animal which is usually selected to demonstrate their presence. If a dog be brought within the sphere of the deleterious vapour, which remains within eighteen inches of the surface, its respiration immediately becomes affected—the abdomen contracts—the eyes are fixed—and the tongue, now of a livid hue, hangs out during the first minute, while, in the next, the animal is totally deprived of motion. Death would inevitably follow, but, on being speedily withdrawn, the lungs resume their play, and the creature gradually recovers its wonted strength and vigour; nevertheless a severe shock is sustained, as the same dog cannot support the experiment above twelve or fifteen times without destruction; in which event it dies in convulsions. The Abbe Nollet, on stooping to inhale the vapour, felt as if he had swallowed boiling water on the first inspiration, yet producing no painful sensations. On lowering his face, a kind of suffocation was experienced; and probably, had the experiment been continued longer, dangerous consequences would have ensued. The vapour is whitish, and possesses some degree of heat. It never rises above eighteen inches from the earth; and a torch immersed in it is extinguished, while the black smoke rolls over its surface without penetrating deeper. GROUSE. See Ornithology *Index.*

GRUYERES, is the name of a small town of Switzerland, in the canton of Friburg. It is situated at the foot of the mountains of this canton. The territory of Gruyeres, is 8 or 10 leagues long and 4 broad; and it is principally celebrated for the excellence of its cheese, which is esteemed the best in Switzerland. The best is made in the pastures of Molesson, and in the mountains of the vallies of Bellegarde and Charmey. It sells at 2½ louis per quintal; and the merchants of the country sell it at 6 batz, or 18 French sous per pound. There are large magazines of this cheese at Bulle, a town about a league from Gruyeres. The view from the summit of the Molesson, which is near the town, is very grand. It may be ascended in three or four hours.

GRYLLUS. See Entomology.

GUADALAXARA, an intendancy of New Spain, and part of the kingdom of New Gallicia, is situated between 19° and 23° North Latitude. Its greatest breadth from the port of San Blas to the town of Lagos, is 100 leagues; and its greatest length from south to north 118 leagues. It is traversed from east to west by the Rio de Santiago, a considerable river, which communicates with the lake of Chapala. It contains two cities, six villas, and 322 villages. The principal city Guadalaxara, the residence of the intendant, the bishop, and the high court of justice, is situated on the left bank of the Rio de Santiago, and contains about 20,000 inhabitants. San Blas, a sea port, and the residence of the marine department, is situated at the mouth of the Santiago, and is a very unhealthy place. The eastern part of the province is the Table Land, and western declivity of the Cordilleras of Anahuac. The maritime district, especially towards the great bay of Bayonne, is covered with forests, and supplies excellent timber for ship-building. The interior of the country enjoys a temperate and salubrious climate. The Volcan de Colima, in the northern extremity of the province, is the most western of the volcanos of New Spain, which are placed in one parallel on the same line. It is estimated to be 10,000 feet in height, but is rarely covered with snow. The lake of Chapala, in the vicinity of Guadalaxara, is nearly 160 square leagues in extent. The superficial extent of the province is 9612 square leagues; and the population in 1803 was 630,500, which gives 66 inhabitants to the square league. The value of its agricultural produce in 1802, consisting in maize, wheat, cochineal, &c. amounted to 568,531*l.* sterling; and the value of its manufacturing industry, composed chiefly of woollen and cotton stuffs, tanned hides, and soap, was estimated at 722,351*l.* The revenues of the bishop are 90,000 double piastres. This province abounds in silver mines, and affords excellent pastures. On the coast, in 21° 28′ North Latitude, are the three Marias islands, the most northern of which is about 13 miles in length, and 9 in breadth, surrounded by white rocky cliffs; and another, about 24 miles in circuit, separated from the last by a strait six miles broad, and which Dampean called Prince George's island, abounds in vegetable productions, but is deficient in fresh water. See Humboldt's *Political Essay on the Kingdom of New Spain*, vol. ii. and *Mod Univ. Hist.* vol. xxxix. (*q*)

GUADALOUPE, the largest and one of the most valuable of the Caribbee islands, lies between Antigua and Martinique. Its length is between 60 and 70 British miles, and its greatest breadth about 25. The middle of the island is situated in about 16° 20′ North Latitude, and 62° West Longitude. Guadaloupe has somewhat of the form of a crescent, and may be considered rather as consisting of two islands than of one; for it is divided into two parts by a narrow strait called Salt River. For a short distance on each side of this strait, the breadth of the island is not more than four miles. By this remarkable channel, the sea on the north-west communicates with the sea on the south-east. Its breadth varies from about thirty to eighty yards; and it is navigable for vessels not exceeding fifty tons burden. The north-west of the island is divided into Basseterre and Cabesterre; the eastern division of it is named Grandeterre. That portion of the island from which the whole takes its name, is, towards the middle, full of high and rugged rocks, where the climate is so cold and the soil so barren, that little vegetation is to been seen. Over the summit of these rocks, the mountain called La Souffriere, or the brimstone mountain, rises to a great height. This mountain of sulphur continually sends forth, through various apertures, a thick black smoke, frequently mingled with sparks of fire. It is of a singular form, being divided into two parts by a remarkable channel, navigable by boats. There are many marks of volcanos in other parts of the island. On a part of the western shore, the sea is so hot at a small distance from the beach, as to boil eggs; and the sand on being stirred, emits a strong sulphureous odour. The island contains a boiling fountain, and a hot marsh, which is very deceitful, and dangerous to strangers. The islands, of which Guadaloupe is the chief, were discovered by Columbus in his second voyage, when he visited Dominica, Guadaloupe, and Antigua. But they were at that time neglected by the Spaniards, in their eager lust of dominion and gold on the larger islands, and on the American continent, the unexplored treasures of which were then opening to their ambition.

No European nation had taken possession of Guadaloupe, when an expedition of five or six hundred Frenchmen, under two adventurous leaders, arrived from Dieppe in June 1635. The new settlers soon commenced a war with the native Caribs, for the purpose of supplying themselves with provisions, of which their own exertions could not yet produce a sufficient quantity for their subsistence. Many of these poor, simple and undisciplined people, unable to maintain a regular struggle with their more skilful invaders, retired to some of the other islands. Others of them concealed themselves in the natural strongholds and recesses of their own, and having previously destroyed their plantations and stores, their superior knowledge of the country enabled them to sally out unexpectedly, and to inflict vengeance on such straggling parties of their oppressors as fell in their way. After a struggle, which was kept up with various success, and which at length produced a terrible famine, a peace was patched up between the contending parties in 1640; and the remnant of Europeans, who had escaped the calamities which they had drawn on themselves, were joined by some discontented sailors and colonists from St Christophers. The superior advantages of Martinique as a sea-port, induced many adventurers to leave Guadaloupe, and pass over to that island; and from this time the French administration bestowed for some years almost exclusive attention on the latter, which became the seat of government of the French islands. For the first sixty years of its occupation by the French, Guadaloupe made little progress; but in the course of the ensuing fifty-five, its improvement was as rapid as it had formerly been slow. In April 1759, the island was conquered by the English. In July 1763, it was restored to its former owners in a highly improved condition. The French government now began to see the value of this settlement, and an independent government was given to it. The island was taken by the British in April 1794, but was retaken by the French under Victor Hughes in February 1795.

Early in 1810, an English expedition, the naval part of which was conducted by vice-admiral Sir A. Cochrane, and the military force by lieutenant-general Sir G. Beckwith, prepared with the design of attacking Guadaloupe and St Eustatius, was ready to commence operations. It was completely successful; and thus the enemy were deprived of the last of their possessions in the Columbian islands.

Guadaloupe continued under the power of the British crown till 1813, when in a treaty, dated March 3d, between his Britannic Majesty and the King of Sweden, it was agreed, that this valuable colony should be ceded to the latter, in consideration of an engagement on his part to furnish a force of 30,000 men, in aid of the allied powers against France. Swedish commissioners were accordingly sent, to make arrangements for taking possession of the island; but in consequence of certain political causes not yet fully explained, it was restored to its old possessors the French, at the restoration of Louis XVIII. in terms of the general treaty of peace, signed May 30th 1814. On the return of Bonaparte from Elba in 1815, General Boyer, the governor, hoisted the three-coloured flag. After the second restoration of the Bourbons, he was condemned to death, but the sentence has been commuted into twenty years imprisonment. The sum of one million sterling was the compensation given to Sweden, for our non-fulfilment of the stipulation by which it was to be delivered into her hands. The general astonishment and indignation of the people of Great Britain and Ireland, on finding, that by one of the articles in the treaty with Louis, the slave trade was to be permitted to be carried on by the French for five years, in this island and Martinique, which British generosity had restored, are not easily described. Petitions poured in upon both Houses of Parliament, and addresses to the Prince Regent from every part of the united kingdom. In consequence of these petitions, Lord Castlereagh, the British negociator, was employing all his influence and skill in order to undo what he had done, and to induce the government of Louis to receive these islands under the express condition, that the odious traffic should instantly be definitively and for ever abolished by France. The consideration of this subject was taken up by the congress assembled at Vienna. But there appeared every reason to believe that our benevolent endeavours would have failed of success, when the irruption of the exiled usurper into France once more transferred this island to the sovereignty of Napoleon Bonaparte. By a stroke of policy, intended at once to show his power, and to conciliate the people of England, he issued a decree as soon as he felt himself replaced on his trembling throne, by which he declared the slave trade to be abolished in the French islands. In doing so, indeed, he made no kind of allusion as to the immorality and wickedness of the traffic with Africa. Besides, he knew that while the war should continue, and England ride triumphant on the sea, he could carry on little foreign trade of any kind, and that these islands would probably fall speedily into our hands; so that the sacrifice he appeared to make of interest to duty, was in fact only a nominal one, and as his decree was expressed just as coldly as if he had been prohibiting the importation of flax or grain, he could easily, he well knew, and without any appearance of gross inconsistency, by another of his imperial decrees, restore the trade, on the ground of alleged expediency, whenever he might be able to derive any advantage from the renewal. This decree of Bonaparte, however, though no one could be deceived as to its motive, had a happy effect on the great cause; for when Louis was a second time restored to his throne in the summer 1815, and when these islands, once more in the power of England, were to be delivered up to France, the example of Bonaparte himself could be quoted, to shame the new government into accordance with our wishes. Indeed England had now the means and the right to enforce compliance with her request. Accordingly Louis, soon after his return, by a royal decree, declared the French slave trade to be definitively and absolutely abolished.

The unsettled state of this island, may probably have prevented any very accurate estimate either of its trade or population since the French revolution. In the year 1700, the population amounted only to about 382 indigenous inhabitants or Caribs; 325 free negroes; and 6725 slaves.

In 1755, there were

| | |
|---|---|
| Whites | 9643 |
| Slaves | 41,140 |
| Sugar houses | 334 |
| Banana trees | 2,028,520 |
| Ditches of manioc | 32,577,950 |
| Horses | 4946 |
| Mules | 2924 |
| Asses | 125 |
| Beeves | 13,916 |
| Sheep and goats | 11,162 |
| Swine | 2444 |

In 1767, France received from Guadaloupe,

| | |
|---|---|
| Fine sugar | 140,418 quintals. |
| Raw sugar | 23,603 quintals. |
| Coffee | 34,205 |
| Cotton | 11,955 |
| Cacao | 456 |
| Ginger | 1884 |
| Campeachy wood | 2529 |
| Confections | 24 boxes. |
| Liqueurs | 165 boxes. |
| Potassia | 34 casks. |
| Skins | 1202 No. |

These articles were sold in the colony for 7,103,838 livres, while the articles imported from France cost 4,523,884 livres, leaving a balance in favour of the colony of 2,579,954 livres.

In 1767, Guadaloupe contained

| | |
|---|---|
| Whites | 12,700 |
| Blacks, or free Negroes | 1350 |
| Slaves | 100,000 |
| Horses and mules | 9220 |
| Horned cattle | 15,740 |
| Sheep, swine, and goats, | 25,400 |

It possessed at the same time,

| | |
|---|---|
| Feet of cacao | 449,622 |
| Feet of cotton | 11,974,046 |
| Feet of coffee | 18,799,680 |
| Sugar houses | 388 |

In the year 1775, eighty-one vessels returned to France loaded with the following produce:

| | | Value in Europe. |
|---|---|---|
| Raw sugar | 188,384 quintals. | 7,137,930 livres. |
| Coffee | 63,029 | 2,993,860 |
| Indigo | 1438 | 1,222,529 |
| Cacao | 1023 | 71,651 |
| Cotton | 5193 | 1,298,437 |
| Skins | 727 | 6973 |

and some other articles of minor importance.

The value of the imports and exports was, in

| | | Imports. | Exports. |
|---|---|---|---|
| 1767 | livres | 4,523,884 | 7,103,838 |
| 1788 | | 5,362,000 | 15,053,000 |

Several productions of Guadaloupe were formerly sent to Martinique; and America received some of its liqueurs, and other commodities, and sent in return, wood, cattle, flour, and cod fish.

In 1789, the population of all descriptions was about 104,000. The island is well stored with horned cattle, sheep, horses, &c. and produces a vast abundance of sugar, coffee, rum, ginger, cocoa, logwood, &c.

GUIACUM. See Chemistry.

GUAM, or Guahon, as it is called by the natives, is an island in the eastern seas, forming one of the group denominated Ladrones, or Marianne Islands. According to the computation of the Spaniards, it is about 120 miles in circuit, apparently flat and even from a distance, but the east coast, on nearer approach, is found to be high and shelving, fenced with steep rocks which oppose the perpetual beating of the sea. Here there is no anchorage, but the west side is divided into small low and sandy bays, one of which, called Umata, constitutes a good harbour for a few vessels, and is defended by a battery of twenty guns. The surface of the island gradually rises from the shore to nearly the middle. The rocks are chiefly granitic; and the centre of the pebbles found on the beach, contains various coloured crystals. Several vallies are interposed between the shore and the inland parts, where vegetation becomes profuse. They appear to have been the bed of so many currents; and their soil consists of sandy earth, mixed with decaying madrepores, from which the sea seems to have withdrawn. The interior, however, is of extreme fertility, abounding with all that can be desired for the use of man. Numerous fountains spring from the rocks, and in their course form transparent pools, shaded by trees, always preserving an agreeable freshness amidst the heats of the climate. But there are no rivers of importance; the other waters being either torrents from among the hills, or inlets of the sea.

No portion of the globe is more copiously supplied with vegetables than Guam; and here our celebrated circumnavigator Dampier first discovered the bread-fruit, an invaluable plant, which affords subsistence to so many thousand islanders of the South Pacific Ocean. The forests are full of guavas, bananas, cocoas, oranges, and limes. Capers are produced in abundance from a shrub, indigenous to the soil, of beautiful appearance, flourishing throughout the year, and exhaling a delightful odour. From hence it has been transplanted to the Philippine islands. Two species of banana are thought peculiar to Guam; one of dwarfish size, only three feet in height, but producing a fruit so much superior to all the rest, that its cultivation has been recommended in the European tropical colonies; the other is the wild banana, a large tree, the fruit of which is not eatable. Of the cocoa tree there are three kinds: *first*, the common species, disseminated throughout India, bearing a nut, which is a great article of subsistence; *secondly*, a middle-sized tree, which is lower, the nut having a tender shell, and a kernel tasting like an artichoke bottom; *thirdly*, the black cocoa tree, rising at most to eight or ten feet in height, with a nut perfectly round, about three inches in diameter, and very delicate. This last affords oil more abundantly than the others, as also coire for cordage, and the leaves of all the three are equally suitable for thatching huts and making mats.

Fish is plentiful on the shores of the island, though frequently of a poisonous quality, originating, it has been conjectured, either from their feeding on the polypi of madrepores and coral, or other marine animals. It is affirmed, that the very taste of the coral is imparted to them. Turtle are large and numerous; besides which the streams of Guam afford abundance of aquatic tribes peculiar to themselves. But the facility with which subsistence of a different description is obtained, renders that which may be derived from the waters quite of secondary consideration, and it is little sought after.

It has never been explained, what are the birds and quadrupeds which are indigenous to the island. A few cattle, that were carried thither long ago, have multiplied exceedingly, and run wild in the uninhabited districts. They are large, and well fed, and exhibit one remarkable feature common to those resuming their original state, in almost all being white, with black ears. It is known, that in Great Britain the few which remain unmixed from distant ages, and have preserved their pristine ferocity, retain along with it the same peculiarity, which is of much interest to the zoologist. Some years ago, the Spaniards transported a large species of deer from the Philippines to Guam, which undergoes so great a change along with the season as scarcely to be recognizable as the same animal. From December to May, its winter coat is long, thick, and of a grey colour; but from the month of May, the hair is brown, or almost yellow, smooth, and shining, having three black streaks on the back, interspersed with white. It multiplies in the woods, which are also well stocked with wild hogs.

Dampier describes the natives of this island as "strong bodied, large limbed, and well shaped. They are copper coloured like other Indians; their hair is black and long; their eyes meanly proportioned; they have pretty high noses; their lips are pretty full; and their teeth indifferent white. They are long visaged, and stern of countenance; yet we found them to be affable and courteous." These people have a great tendency to corpulency, and are very subject to leprosy, or a kind of cutaneous disease, especially in the wet season, or between June and October. They are particularly characterised by mildness and hospitality, which have enabled their invaders to make deeper encroachments on their liberty, than if they had displayed a more repulsive disposition. They are indolent, prone to intoxication, and fond of music, dancing, and cock-fighting. The Spaniards have rendered them acquainted with agriculture; and, to facilitate their labours, they tame the wild cattle, which are trained to carry loads throughout the island. Several are kept for this purpose by most families, becoming perfectly tractable, and as quiet as horses. They are guided by a halter penetrating the septum of the nose, to which they grow accustomed in a fortnight. No part of the industry of the natives of Guam appears to have existed anterior to their conquest; they have either been explicitly taught, or acquired what they practise from example. Some of the mechanical arts are practised by them in carpentry, smith-work, brick-making; and they fabricate cloth, cordage, and even cables, for the Acapulco galleons from the wild banana, which are reputed of superior strength to those manufactured of the best European hemp. But there is one branch of the arts in which they have remained stationary since the discovery of their island, namely, the construction of their canoes; and this has arisen less from want of skill to make the alteration, than from their having already adopted the best possible form of which their local situation admitted. Celebrated navigators have repeatedly expressed their admiration of these vessels, which are equally calculated to keep the sea, and to take advantage of the prevalent winds. Some of their canoes are forty feet long, hollowed out of the trunk of a single tree, and very narrow. A piece two inches deep is sewed on as a washing board to raise it higher; "but what is very singular, one side of the boat is made perpendicular like a wall, while the other side is round, and made just as other vessels are, with a pretty full belly." The ends are sharp, each serves for a prow; and the neighbouring islands frequented by the natives lying chiefly north and south, and the wind being almost constantly east, the rounded side is found on the lee. But there is besides an outrigger projecting from the side, necessary to steady so narrow a vessel, and at the extremity is a log of wood, in shape resembling another canoe, though much smaller. A single mast stands in the middle, with a triangular sail, which, when taken in, is rolled around a yard at the bottom. No canoes are better adapted for sailing. A French navigator assures us, that, with a fair wind, they go at the rate of nine miles an hour, a distance said to be augmented to fifteen under the most favourable circumstances. Dampier observes, "I did here, for my own satisfaction, try the swiftness of one of them. Sailing by our log, we had 12 knots on our reel, and she run it all out before the half minute glass was half out, which, if it had been no more, is after the rate of 12 miles an hour; but I do believe she would have run 24 miles an hour." He was told of one of them having been sent express to Manilla, and performing the voyage, which is about 400 leagues, in the space of four days. However, it is understood, that, although the best sailers known, the canoes of Guam are not safe at sea; but should an accident happen, the natives are so expert at swimming, they are capable of repairing it in the water. The companions of M. Marion observe, that "the form of these embarcations is such, as would do honour to a ship-builder among people who have made the greatest progress in the knowledge of navigation. This form has been imitated from no model, because it differs from all those which men, inhabiting different parts of the world, have given to their vessels."

The inhabitants of Guam are dispersed in twenty-one native establishments, chiefly on the coast, and the town of Agana, situated about twelve miles north-east of the harbour. All the Indian families are agricultural, and each has a small portion of land subdivided into fields or gardens; but the interior of the island is still in a state of nature, covered with thick woods, affording excellent timber for the construction of houses or vessels. The town stands on the shore, at the base of some hills of moderate elevation, in a fine district full of springs, and watered by a small rivulet. Its streets are laid out in a straight line; and the houses, built for the most part of wood, stand on posts about three feet above the ground, and are roofed with tiles or palm leaves. But all the public edifices are constructed of brick. There is a fine church here decorated after the Spanish fashion; and two or three convents or colleges occupied by monks, one of which was established for the education of Indians. The religious establishment of Guam was formerly vested in the Jesuits, who, on the suppression of their order, were supplanted by the Augustines; and besides Agana, there are two or three other cures in different parts of the island. The government house is spacious. There is a royal magazine tolerably well stored, and barracks for 500 men. This being the only Spanish colony in the Ladrones, was preserved with considerable care; however, its chief and most important improvements were derived from the governor Tobias, who was at its head about forty years ago. He taught the natives the proper means of cultivating the land; he planted rice, maize, indigo, sugar canes, and cotton, all of which succeeded admirably, and the maize in particular produced an incredible return. To give them a proper example, this paternal governor formed gardens and plantations, where all necessary vegetables were cultivated, along with the most delicious fruits. He established a kind of cotton manufacture, and caused salt pits to be dug. Further, he instituted a school for the gratuitous education of the native children of both sexes, where they were instructed in reading, writing, and arithmetic, as also vocal and instrumental music; whence strangers have been agreeably surprized, in finding practised musicians assisting the celebration of divine worship in a place so remote from the civilized world. Finding it necessary to provide the island with a sufficient force to protect itself, he formed a militia of 200 Indians, among whom were four Spanish captains, while the remainder of the officers were chiefly Mestees, or the mixed race of Spaniards and natives from the Philippines. But to preserve these troops from the hazard of idleness, and to procure them ample subsistence, they were occupied in cultivating a tract called the Royal Domain, separate from all other property. By such humane and prudent measures, while the natives are reclaimed to habits of industry, their principles and morals, aided by an innate placid disposition, undergo an absolute alteration; yet this patriotic individual was afterwards persecuted by the clergy of Manilla.

The history of Guam is marked by some singular and interesting features. It was discovered in the year 1521, by Magellan, who ascertained that it belonged to a cluster of nine principal islands, and a number of smaller islets, which he first called *De Velas*, from the sails of the canoes, but afterwards *Ladrones*, from the propensity of the natives to theft. Guam appeared to enjoy a delightful climate; it was covered with fruits, and afforded the means of supporting a colony; therefore the Spaniards, having already established themselves in the Eastern Seas, resolved upon making a settlement here. The inhabitants were a wild and savage race; but equally savage with themselves, the Europeans, in usurping their territories, carried fire and sword along with them. In violating the religion of their fathers, they endeavoured to inculcate the principles of Christianity; but, instead of adhering to its mild and benevolent doctrines, they practised the most horrible cruelties to enforce belief. While their rude opponents might have been gained by conciliation, a war of extermination was unrelentingly prosecuted, because their demands, alike ungenerous and unjust, were resisted. At this early period, the nine islands of the group were calculated to contain 60,000 inhabitants, of whom 20,000 belonged to Guam. But they gradually fell under the barbarity of their invaders, too well skilled in warfare. After a long interval of suffering, a measure was at length adopted by the natives, which is scarcely to be paralleled in history: They resolved to allow their race to be extinguished in themselves, that posterity might not be able in their misery to reproach them with existence. Thus the women drank deleterious potions to procure abortion at the moment, and to prevent their having any future offspring; and this outrage against nature was so obstinately persisted in, that about 60 years ago, the total population of the group had decreased to 800 or 900 persons. The Spaniards, however, had awakened from their error, and learning the benefit of conciliation, found means to collect the whole in the island of Guam. There it continued to augment during twenty years, to about 1500, since which time we have no further accounts of it; but most probably it is much more considerable, or part may have colonized the neighbouring islands. During these convulsions the invaders did not escape with impunity, and on one occasion when the natives rose upon them, all the missionaries were massacred; but on another, when their numbers were small, they proved unsuccessful, and all except 100 evacuated the island, leaving the Spaniards in peaceable possession of it. Afterwards they became accustomed to the yoke, and a quiet, peaceable, and inoffensive race has now sprung up to promote, instead of resist, the objects of the settlers.

Guam is of importance as a Spanish establishment from its position and great fertility: the galleons from Acapulco to Manilla, so much the object of capture to hostile nations, were wont to put in here for refreshments, besides which, a vessel came annually from the Philippines. It is said that the natives of the neighbouring islands have become more warlike of late, and seem disposed to make conquests of other territories; but whether they disturb the European colonies is not explained. In concluding these observations, we may cite the words of a French navigator, who made a short residence in Guam, which will satisfactorily illustrate its properties. "In traversing this island, we discovered how lavish nature has been of picturesque and agreeable places. Enchanting spots were met with in our excursions, where she had bestowed every thing, and where the hand of man had made no arrangements. Ennui was banished: here all was united for the enjoyment of solitude: verdure, shade, coolness, and the perfume of flowers: crystalline fountains were seen springing from the rocks: the song of innumerable birds was heard: and groves appeared of cocoas, bread-fruit, oranges, citrons, and an infinity of fruits interspersed among the foliage of trees, all cultivated by the operation of nature alone. Here, too, they presented a pleasing disorder, which art has never been able to imitate. I could not quit this delightful abode without regret, where life might be passed in satisfaction."

It seems doubtful whether the actual position of Guam is completely ascertained. Dampier, after a very long run, lays it down in Latitude 13° 21′ North, Longitude 125° 11′ West: later navigators place it in 13° 25′ North Latitude, and 155° 10′ East Longitude; and La Perouse, probably from observation, fixes the harbour of Umata in 13° 10′ North Latitude. (*c*)

GUAMANCA, Guamanga, or Huamanga, is the name of a city and province in Peru. The city was originally founded by Pizarro in 1539, as a middle station for the trade between Lima and Cusco. It was built at first on the site of an Indian village of the same name; but, in memory of a victory gained over the Ynca, was called by the Spaniards San Juan de la Vittoria. It was situated in the vicinity of the Andes, in a barren district; but, after the subjugation of the Peruvians, was removed to its present site, in 13° South Lat. in a more fertile territory, about sixty leagues east-south-east from Lima. It stands upon the declivity of a mountainous ridge, not remarkable for its height; but still so far above the rivers, as to be scantily supplied with water. About twenty noble families reside in the centre of the town, in spacious houses of a considerable height, built partly of stone, and covered with tiles, and surrounded with extensive gardens. It is skirted with suburbs of Indian habitations, which are chiefly built of stone, and, though low in the walls, as is generally the case in the inland towns of South America, yet add considerably to the appearance of the city. It contains a splendid cathedral, and a seminary for the service of the church, under the title of St Christopher; a university, with professors of philosophy, divinity, and law, and endowed with privileges equal to that of Lima; and also several chapels and convents, a hospital, and a college of Jesuits. It is governed by a corregidor, assisted by the principal nobility, who form a corporate body, out of which are chosen the alcaldes, to superintend the several departments of the police of the city, and the jurisdiction of the province.

The province or diocese lying eastward of Lima, is of very considerable extent, and is divided into the following districts:—Guamanga, which contains the capital of the province, is very fertile and populous. Its climate is temperate, and it abounds in various kinds of grain, fruit, and cattle. It contains several mines, but few of them are worked; and its agricultural wealth is fortunately the principal object of attention to the inhabitants. A principal part of its commerce consists in bend leather, for the soles of shoes; and great quantities also of conserves and sweetmeats are prepared for exportation.—Guanta, about four leagues north-west of the city of Guamanga, and about thirty leagues in length, is likewise a temperate and fruitful district. It is diversified by numerous heights, woodlands, and broken glens, rich in fruits and pastures. Its silver mines, which were formerly very rich, are now almost exhausted; but there are still many of lead; and this metal, together with salt and provisions, are its principal articles of trade.—Vilcas Guaman, about seven leagues south-east of Guamanga, is celebrated for its esculent vegetables and fine pastures, and breeds vast quantities of cattle. The natives are employed in various manufactures, particularly woollen stuffs, which are carried to Cusco and other provinces. There is still remaining in this district one of the old Indian fortifications.—Andaguaylas, to the south of Guamanga, extends about twenty miles eastward, between two branches of the Cordillera, and is watered by a number of small rivers descending from the hills. This extensive valley produces all kinds of fruit and grain, particularly maize and sugar cane. It is one of the most populous districts in the country; and in it many of the wealthier inhabitants of Guamanga have large sugar plantations. Guanca Velica, or Huanca Belica, commencing about thirty leagues north of Guamanga, is a bleak, hilly, and barren district. It produces little fruit or grain, and its inhabitants are supplied with provisions from the neighbouring countries. It is chiefly celebrated for an immense and apparently inexhaustible mine of quicksilver, to the working of which the inhabitants owe their chief subsistence. In the mountains are many shells and marine substances, and in a river near the principal town such large petrifactions are formed, that they are frequently used in building houses and other works.—Angares, about twenty leagues west-north-west from Guamanga, and about twenty leagues in extent, is tolerably temperate and fruitful, and yields vast herds of all kinds of cattle.—Castro Virreyna, south-west of Guamanga, is of very various temperature, but in its bleakest parts its greatest wealth is found. This consists in the wool of a species of sheep, called Vicunna, which had been improvidently hunted down for the sake of its fleece, and which is now to be found only in the coldest heathy spots.—Parina-Cocha, about twenty leagues south of Guamanga, is fertile in grain, and rich in pastures; and its mountains contain several mines of gold and silver, which yield these metals in great abundance, and supply its principal article of commerce.—Lucanus, about thirty leagues south-south-west of Guamanga, is of a cold temperature, but its vegetable productions are abundant, and its herds of cattle numerous. It abounds in rich mines of silver, and is the centre of a very considerable commerce. See Ulloa's *Voyage to South America*, vol. ii.; and Playfair's *Geography*, vol. vi. (*q*)

GUANAXUATO, an intendancy of New Spain, lies between the 20° 55′ and the 21° 30′ North Lat. and is wholly situated on the ridge of the Cordillera of Anahuac. Its length, from the lake of Chapala to the north-east of San Felipe, is fifty-two leagues, and its breadth, from the Villa de Leon to Celaya, is thirty-one. Its principal cities are, Guanaxuato, or as it is also called Santa Fe de Gounajoato, in 21° 0′ 9″ North Lat. built by the Spaniards in 1554, surrounded with mines, and containing 70,600 inhabitants; Salamanca, a neat little town, situated in a plain; Celaya, in which are several splendid buildings, and particularly a magnificent church of the Carmelites; Villa de Leon, in the midst of a highly fruitful district; and San Miguel el Grande, celebrated for its industrious inhabitants, who are employed in cotton manufactures. The province, which is part of the old kingdom of Mechoacan, was first cultivated by the Europeans in the sixteenth century, who expelled the Indian tribes of hunters and shepherds, and supplied their place with colonies of Mexican or Aztec Indians. During a considerable period agriculture made greater progress than mining, and during the seventeenth and eighteenth centuries, most of the mines were entirely abandoned. But, during the last forty years, the mines of Guanaxuato have yielded a greater metallic produce than Potosi, or any other mine in the two continents; and it is now the first mining district in America. Of the situation and products of its mines, a minute description is given by M. Humboldt, both in the historical account of his travels, and in his *Political Essay on New Spain*, vol. iii. p. 169. One of these mines alone, that of Valentiana, which has been known only for forty years, has sometimes furnished, in one year, as much silver as the whole kingdom of Peru. This fine province also is, relatively, the most populous in New Spain. Its superficial extent is only 911 square leagues, and it contains 517,300 inhabitants, which gives 586 to every square league. The principal natural curiosity in this province, are the hot wells of San Jose de Comangillas, which issue from a basaltic opening, and of which the temperature was found to be 205°.3 of Fahrenheit. See Humboldt's *Political Essay on New Spain*. (*q*)

GUATIMALA, one of the three audiences or kingdoms into which Mexico or New Spain was formerly divided, lies between $7\frac{1}{2}$° and 22° North Lat. extending upwards of 300 leagues along the south coast, and in no place exceeding 160 in breadth. It is in some parts extremely narrow, and on the north coast is deeply indented by the Bay of Honduras. It has been divided into thirteen provinces, according to some accounts, and according to others into eight. The latter of these is here adopted, because it best corresponds with the map given in this work, and also because the limits of the thirteen departments have not hitherto been accurately ascertained.* Veragua, the most southern province, and bordering on Panama, is about fifty leagues from west to east, and from nine to twenty-seven in breadth. It was discovered by Columbus in 1502, and was granted to him and his posterity as a reward of his services. Its coasts are low, and full of brushwood; but the interior parts are hilly, covered with forests, very imperfectly explored, but known to abound in rich silver mines. Its principal river Veragua is remarkable for the verdant hue of its waters; and from this circumstance its discoverer gave it the name of Verdes Aquas. Its principal towns are, Conception, considered as the capital of the province, a small place, situated near a river of the same name; Santiago al Angel, built in 1521, but frequently destroyed and restored; Santa Fé, a small town and bishop's see in the middle of the province; and Pueblo Nuevo, or New Town, situated in an unhealthy spot at the mouth of a river, about twenty-three leagues south-west of Santa Fé. There are besides upwards of thirteen villages, inhabited by Indians. Costa Rica, or Rich Coast, north-west of Veragua, is from fifty to sixty leagues in length, and forty in breadth. It consists chiefly of mountainous and woody deserts, and is thinly inhabited and little cultivated. Its mines were formerly productive, but have been abandoned on account of the difficulty of working them; and its chief articles of trade are hides, honey, and wax. Its principal town is Cartago, a small place and Bishop's see in the interior of the province, where the governor resides. Nicaragua, in 12° North Latitude, is about 80 leagues in length, and 50 in breadth, running from north-west to south-east, between Costa Rica and Honduras. It consists for the most part of high woody mountains, in which are some volcanos, but no mines. There is a large lake, 200 miles in circumference, in the south-west, which communicates with the Atlantic ocean by the river St Juan. Its vallies are well watered, and its principal products are timber of great size, cotton, sugar, honey, wax, cochineal, and fruits. Its chief towns are Leon de Nicaragua, a place of considerable trade, on the north-west border of the lake, several leagues from the south coast; and Granada, a populous and trading town on the west border of the lake, near a rugged volcanic mountain. The eastern coast is surrounded with shoals, and has no proper harbour. Honduras, in 15° North Latitude, extends 180 leagues along the south border of the gulf of that name, and from 25 to 50 from north to south. It is well watered by many streams which run northward into the gulf, and which, overflowing their banks in the rainy season, render the soil extremely fertile. Its bay, which includes a compass of 500 miles, is of dangerous navigation; but celebrated for the excellent logwood, which abounds on its flat and marshy shores. There are several islands along the coast of this bay; one of which particularly, Rattan, about 10 leagues in length, was long the resort of pirates, till the British established a colony upon it, for the protection of the trading vessels. The chief towns of the province are, Valladolid, a bishop's see, a small inland town in a pleasant valley; St Jago, 100 miles east of Valladolid; Truxillo, 125 north-east; and Puerto de Cavallos, about 90 north-west; all formerly places of considerable trade, but now greatly deserted. The British established a settlement in 1730 on the Black river, 26 leagues east of Cape Honduras, and another on a navigable river near Cape Gracias da Dios, where there is a secure and spacious road for ships. Guatimala, in 14° North Latitude, bordered on the south and west by the Pacific Ocean, is a province of considerable importance. Its surface is mountainous, and it is extremely subject to earthquakes; but its vallies are remarkably fruitful, abounding in grain, sugar, cotton, various dyeing drugs, especially indigo of a superior quality, and the richest pastures, stocked with incredible multitudes of cattle. Its capital, St Jago, or Guatimala, a bishop's see and the seat of a university, is a considerable trading town. It formerly stood in a delightful valley, not far from the west coast, but was repeatedly destroyed by tremendous earthquakes and volcanic eruptions; and was at length removed to a beautiful plain about 8 leagues from its former site. Nearly 30 leagues to the south-east is Sansonata, or Trinidad, which is the nearest proper harbour for ships from Panama and Peru, trading with St Jago. Verapaz, or Coban, in 16° North Latitude, at the bottom of the bay of Honduras, and north of Guatimala, is about 35 leagues in length, and 30 in breadth. It is a mountainous country, covered with forests; but a few cultivated tracts yield plentiful crops of maize. Cotton, wool, cocoa, honey, wax, and gums, are its chief articles of trade. It contains no towns of any importance; and Vera-paz, the governor's residence on the bank of a river running south-east to Golfo Dolce, Acarabatlan, a small place to the westward, esteemed for its musk melons, and Robinal, a trading village in the pleasant valley of St Nicolas, are scarcely worthy of being noticed. Chiapa, north-west of Vera-paz, in $16\frac{1}{2}$° North Latitude, is of a triangular form, and each of its sides extends about 65 leagues. It abounds in hills covered with forests, and has two rivers, the Chiapa, running eastward to the bay of Campeachy; and the Samasinta, which traverses the eastern part from south to north. It has no mines of gold or silver; and its riches consist in grain, fruits, and pastures. Its principal town, Cividad Real, a bishop's see, is situated in a valley surrounded by mountains, about 90 leagues north-north-west of Guatimala, and trades in cotton, cocoa, and cochineal. There are several Indian towns in this province, of which the most populous is Chiapa dos Indos, about 12 leagues westward of Cividad Real, situated in a valley watered by the river Tabasco. The natives of this diocese obtained, through the mediation of the Bishop Cacas, exemption from slavery, with other signal privileges. Soconusco lies between Chiapa and the Pacific Ocean, and is about 35 leagues in length and 30 in breadth. It is a mountainous country, but has no mines. It is covered with forests, and its vallies produce indigo, cocoa-nuts, fruits, and pastures. The only settlement worthy of notice is Guevitlan, or Soconusco, which is the residence of the Spanish go-

* The celebrated traveller M. Humboldt has furnished a complete description of the modern division of New Spain into Intendencies; but he has not touched upon the portion comprehended in Guatimala, for which he mentions that he had no data, and which we can therefore describe only under its ancient divisions.

vernor, and is situated near the coast of the South Sea, about 40 leagues south of Chiapa. See *Modern Universal History*, vol. xxxix; and Playfair's *Geography*, vol. vi. (*q*)

GUAXACA, or more properly OAXACA, is the name of a city and intendancy in Mexico, or New Spain. The city, which is the ancient Mexican Huaxyacac, was called Antiquera at the time of the conquest. It is situated in an extensive and populous valley, about 80 leagues south-east of Mexico. It carries on a considerable trade, and is particularly celebrated for its excellent chocolate. It is handsomely built, and contains a very fine cathedral, but is open and unfortified. It is a bishop's see, and in 1792 contained 24,000 inhabitants. The province of Guaxaca lies in 17° North Latitude, reaching from sea to sea, extending about 90 leagues along the south coast, 30 along the Mexican Gulf, and from 30 to 70 in breadth. Its climate presents a perpetual spring, and it is one of the most delightful countries in that quarter of the globe. Its mountainous districts, composed of granite and gneiss, are rich in mines of gold, silver, and lead. Its plains are highly fertile, and yield abundance of sugar, cochineal, fruits, grain, and various useful productions. Its relative population is equal to that of European Russia, and it has been long advancing in civilization. Throughout the whole province, vegetation is extremely vigorous, especially half-way down the declivity, in the temperate region, where the rains are very copious from May to October; and, at a small village, about three leagues from the capital, is an enormous trunk of *Cupressus disticha*, which measures 118 feet in circumference; but upon a narrow inspection is evidently composed of three united stems. Many remains of ancient Mexican structures are to be seen in the province, especially at San Antonio de los Cues, a populous place on the road from Orizaba to Guaxaca, and at a village named Mitla. In this last mentioned place, which was formerly called Miguitlan, a word signifying, in the Mexican language, a place of sadness, are the ruins of an extensive palace, constructed over the tombs of the kings, and to which the sovereign used to retire for some time on the death of a son, a wife, or a mother. This palace, or rather sepulchre, consists of three edifices, placed symmetrically in a very romantic situation. The principal structure, which is in the best preservation, is nearly 131 feet in length, and the distribution of the apartments bears a strong analogy to what has been remarked by the French *savans*, in the monuments of Upper Egypt. A stair, formed in a pit, leads down to a subterraneous apartment, which is 88 feet by 26, and which, as well as the exterior walls of the edifice, is covered with those ornaments, generally called *grecques*, such as meanders, labyrinths, &c. some of which are in Mosaic, of small porphyry stones. Several curious paintings have been found in these ruins, representing warlike trophies and sacrifices; but the most striking object is a vast hall, of which the ceiling is supported by six porphyry columns, about 16 feet in height. These columns, the only ones found in the new continent, bear strong marks of the infancy of the art, having neither base nor capital, but simply a contraction of the upper part. Besides the capital, there are several other towns in the province, the principal of which is Tecoantepec, about 40 leagues south of Guaxaca, at the bottom of a bay on the coast of the Pacific Ocean. It is a small town, with a good fishing harbour, and an open road for ships; but the port is impeded by a dangerous bar. It is likely, however, to become a place of greater importance, by the increase of the indigo trade from Guatimala. The family of Hernan Cortez bears the title of Marquis of the valley of Oaxaca, a property containing 4 villas, 49 villages, and 17,700 inhabitants. There are 306 secular ecclesiastics in the province, and 342 regulars. The revenues of the bishop amount to 18 000 double piastres. See Humboldt's *Political Essay on the Kingdom of New Spain*. (*q*)

GAUYAQUIL, a city and province in the kingdom of Quito. The city is the second of Spanish origin in the empire of Peru; and was first built about the year 1535, near the gulf of Charapoto, but, in 1693, it was removed to its present situation, on the west bank of the river Guayaquil, in 2° 11′ 21″ South Latitude, about 63 miles from Quito, and 188 from Lima. It extends along the side of the river nearly half a league, and is divided into an old and new town, both of which contain about 2000 houses, which are built of brick or wood, covered with tiles or thatch, but, on account of the numerous conflagrations by which it has suffered, the latter covering is now prohibited. The ground on which the new town stands, is composed of a spongy chalk, and is every where so level, that, in the rainy season, it becomes utterly impassable either on foot or on horseback, and the communication of the inhabitants is effected chiefly by means of large planks, which soon becoming slippery, afford a very inconvenient path. The place is defended by three forts, two on the river close by the town, and a third behind it, guarding the entrance of a ravine. All the churches and convents are built of wood, on account of the softness of the soil, except the church of St Domingo in the old town, which is of stone; and the country supplies timber well adapted for these purposes, being extremely hard, and capable of retaining its solidity either in the mud, or under the water. The city and its jurisdiction are under a corregidor, who is subordinate to the president and audience of Quito, and holds his office during five years; the police is conducted by ordinary Alcaldes; and the ecclesiastical government is lodged in the Bishop of Quito's vicar, who is generally also the priest of the town. It contains a small college of Jesuits, and an hospital without any endowments. The inhabitants of Guayaquil, including the strangers who are drawn thither by commerce, are computed at 20,000; and many of the principal people are Europeans, who have married and settled in the place. All who are capable of bearing arms are enrolled in companies of militia, according to their rank or cast. Though the heat of the climate is equal to that of Panama or Carthagena, yet it is a remarkable circumstance, that the Spanish inhabitants are extremely fresh coloured, and their children universally fair, having light hair and eye-brows. They are accounted the handsomest people in all Peru, and are said to be equally distinguished by the elegance and politeness of their manners. As the river is brackish near the city, good water is extremely scarce, especially during summer, and is brought from a distance of four or five leagues, by means of boats resembling rafts. The fish also in its immediate vicinity is neither good nor plentiful; but great quantities of the most excellent kinds, particularly shell-fish, are brought from the neighbouring coasts, and constitute a principal part of the food of the inhabitants. As wheat is scarce and the bread from it also badly made, different kinds of roots have been employed as substitutes, particularly unripe plantains cut into slices and roasted. The inhabitants affect great splendour in their formal entertainments; and their dishes are a succession of high-seasoned ragouts and sweetmeats, always beginning with the latter. Their liquors, on these occasions, are grape-brandy, cordials, and wine. Weak acid punch is much used by both sexes, in the forenoon and evening, as a refreshing and wholesome drink, and as a necessary mode of correcting the disagreeable qualities of the water. Melons and water melons are brought in great abundance to the city during the summer season. From the month of May to December, the air is remarkably serene and delightful; and the cool breezes, which blow from the mountains from mid-day till five or six o'clock next morning, tend greatly to refresh the earth and the atmosphere. But during the other half of the year, the climate is intolerable to strangers, the heat greater than at Carthagena, the rains continual, the country overflowed, the insects and other vermin extremely numerous, and even venomous. They are said to be so abundant in the city, that it is impossible to keep a candle burning except in a lantern, as it would otherwise be extinguished in a few minutes by the multitudes flying around it. Tertian fevers prevail much at this season, which the inhabitants, from a prejudice against the use of the bark, (though originally discovered in the province,) suffer to prey upon their constitutions, till they often become incurable. They are very subject also to cataracts and other distempers of the eyes, which often terminate in total blindness, and which some have ascribed to the aqueous exhalations during winter from the chalky soil. The city carries on a considerable trade, and exports native produce, of which the chief article is cocoa, to the value of 550,000 piastres annually; while the amount of imports is 1,200,000 piastres. The province of Guayaquil extends about 60 leagues from north to south, and about 45 from east to west; and is divided into seven departments or lieutenancies, for each of which the corregidor appoints a deputy governor, but whose authority must be confirmed by the audience of Quito. These are Puerto Viejo, a poor and thinly inhabited district, abounding in wood, producing a little cotton, and formerly noted for a considerable pearl fishery in the bay of Manta.—Punta de Santa Elena, a low fertile country, full of salt works, but chiefly remarkable for possessing the purple dye so highly esteemed among the ancients, and which is simply the blood of a species of shell fish growing on the rocks. The threads, after being drawn through this liquor, are tinged at first with a milky hue, which changes into green, and then into a vivid purple, which does not fade by wearing, and is rather improved by washing.—Puna, a low flat island in the mouth of Guayaquil river, about seven leagues square, covered with thickets of mangrove trees.—Yaguache, around the mouth of a river of the same name, which falls into the Guayaquil, has no towns of note, but the country is populous, and produces much excellent wood.—Babahoyo, is a large district, subject to great inundations during winter, but productive in cotton, rice, Guinea pepper, and other fruits, especially in plantations of cocoa. Large droves of horses, mules, and black cattle, which are kept in the mountains during the wet season, are brought down when the land is dry, and fattened on the plant called gamalotte, which, resembling barley in its blade, grows in such luxuriance as entirely to cover the plains, even to the height of 7 or 8 feet.—Baba, a very extensive district, reaching to the skirts of the Cordillera, abounds chiefly in the cocoa tree, which delights in a watery soil, and which here grows frequently to the height of 20 feet. The gathering of its fruit and drying of its seed forms the principal trade of the inhabitants. Daule has many large orchards, and extensive corn fields, plantations of cocoa, cotton, and sugar cane, but is chiefly distinguished by the excellence of its tobacco. Throughout the whole province of Guayaquil numbers of cattle are reared, especially where there are mountainous tracts to afford a retreat during the season of the inundations. The woody parts are much infested with insects and noxious animals. The river of Guayaquil, which is the principal channel of the commerce of the country, is navigable for the space of 24 leagues, from the isle of Puna at its mouth to the town of Babahoyo, where all the goods intended for the Cordillera, or proceeding thence, must be entered. This river is frequently swelled by torrents from the mountains; and, as these floods are continually shifting the sand banks, its navigation is uncertain, and requires constant sounding. It is navigated principally by *balzas*, or rafts, which are made of a soft, light wood, and which are of various sizes, but frequently carry 400 or 500 quintals. (See BALZA.) The principal articles of the cargoes exported from the province are cocoa, timber, salt, and cattle, tobacco, wax, Guinea-pepper, drugs, and ceibo-wool. This last is the product of a high and tufted tree, and bears a greater resemblance to silk than either to cotton or wool. It is chiefly used to fill mattresses, and has this remarkable property, that when compressed by dampness, yet, if laid in the sun, it swells again, and often with such force as to stretch the covering of the mattress. The imports are, wine, brandy, oil, and dried fruits from Peru; bays, flour, papas, bacon, hams, cheese, and similar articles, from Quito; iron and cordage from New Spain; and European goods from Panama. But the principal profits of the Guayaquil traders arise from the commercial exchanges between Lima and Quito, which pass in the course of its river, especially in the summer season, when the goods can be conveyed between the mountainous districts and the shipping. The banks of the river are covered with habitations, and the inhabitants thus enjoy the advantages both of fishing and of agriculture. These houses, like the greater part of what are built in the province, are chiefly of timber, and raised upon posts 12 or 15 feet from the ground, on account of the general inundations during winter. In that season, the inhabitants of the level districts pass from house to house by means of canoes, which even the children are able to manage with extraordinary dexterity. The river of Guayaquil supplies the numerous inhabitants of its borders with abundance of fish; and the Indians after harvest set sail in their balzas with their families, and employ several weeks in fishing; moving from one creek to another, according to their success. Besides using harpoons and nets, they employ in the smoother creeks a certain herb called *barbasco*, which they chew, mix with bait, and scatter on the water. The juice of this herb is so powerful, that it often kills the smaller fish when they eat of it; and so stupifies the larger, that they float on the surface, and are taken up without any trouble. The increase of the fish is greatly hindered by the multitudes of alligators which frequent the river and the adjacent plains; and some of which are fifteen feet in length. They are not ferocious, and uniformly flee at the approach of a man; but they often devour the calves, colts, and even the children when wandering near the river in the dusk; and it is said, that after once tasting human flesh, they become more ravenous, sometimes watching an opportunity to drag the boatmen, while asleep, into the water. The gallinazo, a bird about the size of a pea-hen, and very common in the hot climates of South America, furnishes a useful check to the increase of the alligators, by its activity in destroying their eggs. Concealed among the branches of a tree, it silently watches the female alligator till she has laid and covered her eggs in the sand. As soon as she is gone, the bird darts upon the spot, and, assisted by a multitude of its tribe, who readily join the fortunate discoverer, uncovers the nest, and devours the eggs. See Ulloa's *Voyage to South America*, vol. i. (*q*)

GUAYRA. See CARACCAS.

GUERCINO. The original name of this celebrated artist was *Giovanni Francisco Barbieri*. Malvasia relates, that in his infancy he lost the sight of his right eye, and that from this accident he acquired the name by which he is now generally known. He was born at the village of Cento, in the territory of Ferrara; and little doubt remains that he never received any regular instructions in painting but what he derived from two very obscure artists in his own country, namely, Gio. Batista Cremonini, and Benedetto

Gennari. It has been affirmed, indeed, that he was taught in the school of the Carracci; but this supposition is rendered improbable by a variety of circumstances, and by none more than the peculiarities of his different styles, all of which are at variance with the principles of that school. It is more than likely, however, that he derived much advantage from studying the magnificent picture of Lodovico Carracci at the Capuchins at Cento; but for the great proficiency which he attained, he must be considered as chiefly indebted to the strength of his own genius, and to the careful study of nature. The tendency of his mind began to shew itself at an early age; and it is recorded of him, that when only ten years old, he painted a picture of the Virgin, in the façade of his father's house, which would not have disgraced a more mature age, and a more practised hand. When premature talent is found to ripen into great excellence, we too readily give credit to the stories which blind admiration delights to record of childhood already atchieving what belongs to experience and age. And when his biographers relate that this picture of Guercino, at the age of ten, with such a subject as the Virgin, was actually a picture of *extraordinary excellence*, we may safely class it among those innumerable instances of a like nature, in which exaggeration sets not only what is probable, but what is possible also, at defiance.

In the course of his practice, Guercino adopted three different styles, which he followed at different periods. The first is not distinguished either by accuracy or grace of design; and in respect of colouring and effect, is violent, inharmonious, and harsh. It is a bad imitation of Michael Angelo Caravaggio, whose works at that time were held in high estimation. Dissatisfied with his attainments, he visited the celebrated schools of art at Rome, at Venice, and Bologna, and by great study and observation, he changed and improved his manner; and his second style is free from many of the faults which are observable in his previous works. He still retained that vivid contrast of light and shade which distinguishes the productions of Caravaggio; and, like him, his outlines are generally lost, and blended in the *fondo*, but he now far surpassed him in grandeur of composition, and in dignity of character. His females are remarkable for elegant and fascinating beauty. His men, however, are not always free (even in this his best and most valued manner) from a degree of vulgarity and individuality, which probably arose from too strict an adherence to the mode from which he painted. Among the great performances which he executed at this period, we may reckon the picture of St Petronilla, formerly in St Peter's, and lately removed from the gallery of the Louvre; the Aurora, in the Villa Ludovisi; his St Philip of Neri; his St Glena; and his fine picture of the Resurrection. In a similar style of bold design, and magically forcible effect, both of colouring and of light and shade, he executed his grand undertaking of the Dome at St Piacenza, in which he has carried fresco painting to a high degree of perfection. The late Mr Barry, in a letter dated at Bologna, to Sir Joshua Reynolds, speaks in terms of the highest praise of the pictures by Guercino, at that time in the church of St Gregorio. Speaking of the solemn colouring in the works of Ludovico Carracci, "Guercino," says he, "has much of this manner in his fine pictures at St Gregorio, with this difference, that I observe in Guercino more mellowing and *fuoco* in the colouring;" and he regrets that this great artist should ever have departed from the grave majestic tone which he then practised. Like the great painter to whom he is thus compared, one great excellence of Guercino is the clearness of his deepest shadows. In his best works, he admitted a very large proportion of shadow; yet, notwithstanding their breadth and deep repose, every object which it envelopes is as distinctly seen as it would be in nature. Nothing is lost, nothing is left ambiguous.

From this style, however, he was at an advanced period of his life tempted to deviate. The manner of colouring which Guido had adopted, remarkable for sweetness, openness, and delicacy, was become the subject of great admiration; and Guercino, in attempting to rival the peculiarities of style so widely different from his own, lost all that stamped him an original genius, and fell into a manner of comparative imbecility. In this last manner, were his pictures of the Annunciation at Forli, the Prodigal in the royal palace at Turin, and the Marriage of the Virgin in St Paterniano, at Faro.

This laborious artist left an incredible number of works. In the list given by Malvasia, he enumerates 106 altarpieces for the churches, 144 large historical pictures, besides his great fresco works, and his numerous portraits and landscapes in private collections. He left also a vast number of drawings, which are held in great estimation. The etchings which he executed, nine in number, are very spirited. He died in 1666, aged 76 (*t*)

GUERICKE, Otto. See Pneumatics, *History of*.

GUERNSEY, the *Sarnia* of the ancients, is an island belonging to Great Britain. It is one of the Channel islands, lying within the bay of St Michael, and about seven leagues from the coast of Normandy. This island is of a triangular shape. Its extreme length is about $7\frac{1}{2}$ miles, and its greatest breadth about 4 miles. It is about 21 miles in circuit. According to the recent account of it given by Dr Macculloch, it is elevated to the south, and shelves towards the north. The southern coast is bounded by high cliffs, stretching along part of the eastern coast. The rest of the eastern coast, and the northern coast, consists of a number of flat bays, separated by ridges of lofty rocks. Dr Macculloch conceives the island to be divided by an imaginary line, drawn from the town of St Peter's Port to Pezeries. A level tract, broken only by cairns and rocky hillocks, lies to the north of this line. This tract comprehends an inundation of more than 60 years standing, which covers three hundred acres. It was formerly quite dry before the time of low water, but has lately been embanked and drained. Towards the south of the imaginary line, the country forms a higher stratum, everywhere intersected by deep glens and narrow vallies of various directions. With the exception of two or three narrow caves, which form the mouths of small vallies intersecting the high land, the lofty cliffs which bound the southern tract are continuous. There are here few detached rocks, but the northern coast is covered with them. Dr Macculloch observed, that the island is entirely of granitic formation; that the southern division consists wholly of gneiss; and that the rocks which form the northern point, exhibit various kinds of granite, or granitel. At the foot of a rocky steep, near Prevolet Point, is a curious cave, called *La Cave Mahie*. It is about 200 feet in depth; and from an entrance 9 or 10 feet wide and 6 high, it extends from 50 to 60 feet in height and breadth, ending in granite points.

The soil of Guernsey, which is decomposed gneiss, is very fertile, and is well watered by springs and rivulets. Agriculture is carried on with great care. The lands are inclosed with stone fences. The seats of the gentry, and the farm-houses and cottages, which are very handsome, are agreeably situated among orchards and gardens. The ordinary food of the inhabitants, is a soup made of cabbage, pease, flour, and a few slices of green bacon. Their beverage is cyder. The produce of the island is nearly the same as that of the west of England. The fruits are very fine. Pigs are fed in winter on parsnips; and the butter, pork, and veal, are in the highest perfection. Red and grey mullets, mackarel, congor eels, and lobsters, are caught in great abundance round the island. Coals are imported; but the principal fuel of the poorer inhabitants is sea-weed, the ashes of which are used as manure by the farmers.

The climate of Guernsey is mild and temperate, and is not subject to excessive heats or colds. The winters and springs are moist, and high winds often prevail.

Guernsey is divided into ten parishes, each of which is divided into several vintons, for the better management of affairs. The island is in the diocese of Winchester, and province of Canterbury. The convention of the state, consists of the governor, a bailiff, 12 jurats appointed by the king, who administer the laws, which are quite different from ours. These officers hold their places during pleasure; and they judge in all civil and criminal cases excepting high treason. The governor receives tythes of all kinds of grain. He has under him a lieutenant-governor, who is called the constable of the castle. The prevailing religion is that of the church of England, though the followers of Wesley are numerous. The Catholics are very few in number.

The only town in the island is St Peter's Port. It originally consisted of a narrow street of high houses, but the buildings have been extended across a ravine over the surrounding heights. The lower streets are narrow, dirty, and irregular. The principal church, built in 1312, is of granite. It has Gothic mouldings, though no pointed arches. Its exterior is handsome. Its porch is remarkable for the depth and extent of its mouldings; and its tower is a great ornament from the pier and road. It contains some good modern monuments. The new court-house is handsomely built of granite, and fitted up with suitable offices for the preservation of a few records. The new prison, built after the model of the debtors' gaol at Manchester, is very spacious and commodious. The work-house, or hospital, is supported by an endowment, and by an assessment on lands and houses. The harbour affords sufficient shelter and security to shipping. The keys and the piers are immense masses of rough masonry, formed of granite, and extending out into the harbour. These walls are paved, and have parapets, and they inclose a space of several acres. The harbour and the road are exposed to the south-east. Harbours for vessels of light tonnage occur on the north and west sides of the island, at the creeks of Bazon, L'Accousse, Ferminer, St Sampson, and the west passage. The market-house for meat and vegetables, is a large building, erected in an open square. Two large and handsome rooms have been fitted up above the market-house, for the public assemblies and entertainments, which are held monthly during the gay season. There is also a small theatre here. An ascent of about 100 steps, leads from the level of the market-place up the side of a ravine to the new town, where there are many good and open streets, one of which, called George Row, contains several elegant houses. The government house, the public walks at L'Hivreur, and the college founded by Queen Elizabeth, are the only other objects of interest.

There were formerly four castles in the island, viz. Castle Cornet, the Castle in the Marshes, Vale Castle, and the Castle of Notre Dame. Castle Cornet is situated on a rock of gneiss often approaching to granite, and intersected by veins of quartz, trap, and felspar, curved and mixed in various ways. This rock is about a quarter of a mile from the shore, and near Port St Peter's. It is scarcely accessible but on one side. It is surrounded with an outer wall of great thickness, flanked by several machicolated towers, and the keep has been converted into casemates. Elizabeth enlarged it with a lower line of curtain and bastions; and barracks and accommodation for a numerous garrison have since been formed. It is now defended by a considerable quantity of heavy artillery.

The Castle in the Marshes appears to be very ancient. It is encircled with a double wall of granite, and has an outer and inner ditch, and a keep in the Norman form.

The Vale Castle, which is also ancient, stands upon a commanding eminence, near St Sampson's harbour. It was once reckoned to be strong, but it has now only a surrounding wall, with flanking towers, and a portal. There are barracks for a garrison; and several pieces of cannon on the ramparts, command a passage called the Russel. The castle of Notre Dame, and that of Rocquane, no longer exist.

The inhabitants are chiefly employed in agriculture, and in the cultivation of their gardens and orchards, from which great quantities of excellent cyder are made. The only manufacture is that of woollen goods. They are allowed to import 1000 tons of wool annually from England, which is made into stockings, waistcoats and breeches. Lobsters are the only fish which is exported. Guernsey was, before the establishment of the London Docks, the grand depot of all the foreign wines and brandies. Towards the bay of St Sampson's there is a fine rock of grey or black granite, which is exported in large quantities to London and Portsmouth. It is called the Guernsey or St Sampson's stone, and being hard and tough, it is admirably adapted for building and paving, as it easily breaks into square masses before the hammer. Dr Macculloch could not obtain any physical or historical evidence that emery was a production of this island, as has been generally stated. Every part of the coast of Guernsey is fortified with strong batteries and breast works. The number of houses in St Peter's is about 800, and the population of the island about 15,000.

See Dicey's *History of Guernsey*; Grose's *Antiquities of England and Wales*; and Macculloch's *Account of Guernsey* in the *Transactions of the Geological Society*, vol. i. p. 7.

GUIANA, an extensive country in South America, is bounded by the river Orinoco on the north, by the river of the Amazons on the south, by the Atlantic Ocean on the east and north-east, and by New Granada on the west. It is nearly of a triangular form, and is computed to contain 250,000 square miles. It extends along the coast from the mouth of the Orinoco to that of the Maranon or Amazons river, about 700 miles; and stretches inland from east to west about 1200. The Orinoco is known to communicate by several branch-streams with the Maranon; and one of these, called the Yupura, is considered as the western verge of Guiana. It is therefore completely an insulated tract, and is probably capable of being circumnavigated.

The discovery of Guiana has been attributed by some to Columbus in the year 1498, and by others to the Spanish navigator Vasco Nunes, who, after ascertaining Cuba to be an island, landed in 1504 on the continent of South America; and, having traced the coast from the Orinoco to the Maranon, comprehended the whole tract in that extensive country, to which, in contradistinction to Cuba and the adjacent islands, he gave the general name of Terra Firma. But, though originally seen by the Spaniards, Guiana was little known, till it was visited by Sir Walter Raleigh in the year 1595; who not only explored the coast, but also sailed up the river Orinoco about 600 miles, in quest of the imaginary El Dorado. Several English buccaneers next resorted to the coast; and, in 1634, about sixty persons, partly English and partly French, under the command of a Captain Marshall, were found in Surinam cultivating tobacco, and making trading voyages to the neighbouring coasts. In 1650, this voluntary settlement was taken under the protection of Great Britain, and Lord Willoughby of Parkham was appointed governor; but, in 1667, it was taken by the Dutch, and finally ceded to them by the treaty of Wesminster in 1674, in exchange for the province of New York. Similar settlements were gradually made by other powers, on different parts of the coast; and the country of Guiana has thus been distributed by geographers into four distinct divisions; viz. Spanish Guiana, Dutch Guiana, French Guiana, and Portuguese Guiana. Spanish Guiana extends along the coast about thirty leagues, from the mouth of the Orinoco to Cape Nassau, and runs inland about 150 leagues on the south of the Orinoco; Dutch Guiana lies between Cape Nassau and the river Maroni; French Guiana between the Maroni and the river Carapana; and Portuguese Guiana, between the Carapana and the river of the Amazons. The more inland part of the country, behind these settlements, may be considered as a fifth division, and called Indian Guiana. Of these, Spanish Guiana is by far the most extensive and valuable possession. Its breadth, indeed, for the space of 80 leagues eastward, does not exceed 30 leagues; but it afterwards widens to more than 150 leagues, running along the back of the Dutch and French possessions, till it reaches the equinoctial line, which separates it from the Portuguese territories. It is divided into Upper and Lower Guiana, of which the river Caroni may be considered as the separating boundary. Lower Guiana is intersected in all directions by numerous rivers, which from time immemorial have contributed to increase the vegetable mould on its surface, so that in point of fertility it is not surpassed by any other portion of territory in the American continent. But, for the space of 30 leagues from the coast, it is completely occupied by the Caribs, the most ferocious of the Indian tribes, who have hitherto massacred every Spanish missionary or settler, who ventured to approach their habitations; and whose hostility to the Spaniards, the Dutch have been accused of fomenting, for the purpose of extending their commerce along the coast of Spanish Guiana. The city of Saint Thomas, the capital of Spanish Guiana, is situated on the right bank of the Orinoco, about 90 leagues from the mouth of the river; and is the residence of a governor and a bishop. Its streets are regularly built and well paved; and its climate pure and healthy; but its port is incommodious, and its distance from the coast unfavourable to its commercial prosperity. From this port of Guiana were exported, from 1791 to 1794, 10,380 oxen, and 3140 mules, all either bred in the province or brought from Varinas; and, in return, were imported 200 negroes, and 349,448 piastres in specie. From 1791 to 1795 the silver exported to Europe amounted to 25,203 piastres, and the commodities to 363,397 piastres. But this commerce is said to have greatly diminished. The population of Spanish Guiana, exclusive of the portion occupied by the Caribs near the coast, is estimated only at 34,000, of which 19,425 Indians are under the jurisdiction of the missionaries, 6575 reside in the capital, and the remaining 8000 are scattered through the different villages. Farther particulars respecting the political and ecclesiastical state of this province will be found under the articles Caraccas and Orinoco; and for an account of the other European settlements on the coast of Guiana, we refer to the articles Berbice, Cayenne, Demerary, Surinam, &c. In the present article we confine ourselves to such topics as may be considered common to them all, especially to the natural history of Guiana, comprising its soil, climate, native productions, original inhabitants, &c.

Guiana was originally called by some navigators the wild coast; and its shores, accessible only by the mouths of its rivers, are every where covered by dangerous banks, quicksands, rocks, and impenetrable thickets. Its appearance from the sea is wild and uncultivated; and it is so low and flat, that, even where there are plantations along the coast, there is nothing visible at first but a continued forest, standing close to the beach; so that the country appears as a cluster of trees growing out of the water. The European settlers, particularly the Dutch, attempted at first to cultivate the banks of the rivers, at a considerable distance from the coast; but, by the example of the British, were persuaded to extend their plantations along the shore, where the soil is remarkably fertile, and adapted for every variety of tropical production. The ground, for a considerable way up the country, is every where level; and so low, that, during the rainy season, it is usually covered with water nearly two feet in height. This renders the soil so rich, that, on the surface, for 12 feet in depth, it is a stratum of perfect manure, and has been actually carried to Barbadoes for that purpose. In some places, 30 crops of rice can be raised in succession; whereas, in the West India islands, not more than two is ever expected from the richest lands. The whole country is intersected by deep swamps or marshes, numerous rivers, and extensive savannahs. The interior has been little explored; but, in proceeding inland, it becomes more hilly, and the soil poorer, sometimes rocky, and often sandy. It is covered with immense forests, rocks, and mountains; and, in some of the latter, a variety of mineral substances are found. The most prominent objects are, a lake called Parima, whose extent varies with the seasons; and a chain of mountains called Mei, nearly parallel with the form of the coast. From these mountains, rivers flow in every direction; some, like the Essequebo, falling into the Atlantic; some, like the Caroni, joining the Orinoco; and others, like the Rio Blanco, uniting with the river of the Amazons.

The climate of Guiana is the mildest and most salubrious of any tropical country hitherto inhabited by Europeans. This has been ascribed principally to the regular blowing of the trade-wind over the surface of a vast tract of ocean, which thus carries a perpetual stream of cool air over Guiana from east to west; while, on the opposite coast of Africa, the same equatorial wind, coming over land, is heated with the sultry vapours of sandy deserts. Besides this general flow of the whole atmosphere in a westerly direction, there is a daily lateral fluctuation, termed the sea-breeze and the land-breeze; the former, which is the cooler of the two, blowing from the north-east during the day, temperating the ardour of noon; and the latter, which is the warmer of the two, blowing from the south-east during the night, preventing too rapid a chillness. The range of the thermometer on the coast, during the whole year, is from 72 to 87; and, between two or three hundred miles up the country, it is from 65½ to 84. Instead of the cold and the warm seasons of Europe, the year is divided by the rainy and the dry seasons, which may be termed the winter and summer of the country. But, in Guiana, there may be said to be annually two winters or wet seasons, and two summers or dry seasons, which are distinguished from each other by the appellation of the *greater* and the *smaller*, referring not to the intensity of the heat, or the violence of the rains in the one more than the other, but to their duration. The long wet season begins about the middle of April, declines in August, and ceases in September; when the short dry season commences, and continues till the middle of November. Then comes on the short wet season, which lasts till the middle of January, when the long dry season appears, which does not terminate till the middle of April. During this last period, especially in the month of March, the weather is most pleasant, the atmosphere clear and pure, the climate genial and cool. There are frequent variations in these stated periods; and the changes are generally accompanied with tremendous storms of thunder and lightning, which sometimes prove fatal both to the inhabitants and the cattle of the country. In the wet season, though the rain falls in torrents, yet it is generally in the afternoon; and in the dry season, there is rarely a drought, but showers occasionally come during the night. The earth is thus, during the whole year, adorned with perpetual verdure, the trees loaded at the same time with blossoms and ripe fruit; and the whole presenting to the view a delightful union of spring and of summer. There are no hurricanes to destroy the crops of the planter; and rarely are any earthquakes felt in the level districts.

There are few contagious disorders in Guiana; and by temperate living, together with proper care to avoid the mid-day heat and evening dews, Europeans have been able to preserve a state of excellent health in the country. The principal disease is fever, in a variety of forms and degrees, from the simple intermittent to the dreaded yellow fever. A prickly heat, or scarlet eruption, is frequently experienced, which causes extreme itching, but is considered rather as friendly to health. The stings of the musquitoes or gnats are often succeeded by large pimples, which are apt to be converted by scratching into troublesome ulcers. The ring-worm consists of long scarlet spots, chiefly about the face and neck, and is prevented from spreading by the immediate application of lime-juice mixed with gun-powder. The chigoe, or jigger, is a kind of sand-flea, which lodges under the toe-nails, between the skin and the flesh, and, unless extracted as soon as the itching which they occasion is felt, are apt to produce very deep and fretting ulcers. The yaws, a dreadful disorder resembling the small-pox, and covering the body with large ulcers, is extremely infectious, but seems peculiar to the negro race. Dry gripes, bloody flux, and dropsy, are also frequent.

The vegetable productions of Guiana are exceedingly numerous, and many of them particularly worthy of notice, both as objects of curiosity and as articles of utility. The trees in the forests grow to an immense size, many of their trunks rising to the height of 100 feet, and throwing out at the lower extremity a number of flattened projections, which surround the stem like supporting buttresses, and form deep recesses, capable sometimes of affording shelter to 10 or 12 persons. The mountain cabbage, unrivalled in the vegetable world, has a straight tapering trunk 100 feet in height, and 7 or 8 feet in circumference, branches 20 feet in length, diverging in a horizontal direction, palmated narrow leaves above 2 feet long, a green husky pod 20 inches in length at the clefts of the lower branches, full of nuts, which are the seeds of the plant; and, on the summit of the trunk, the cabbage, consisting of thin white strata, and resembling an almond in taste. The silk cotton tree, generally growing to the height of 100 feet, with a trunk 12 feet in circumference, and free of branches for the space of 70 feet, bears a pod full of silky filaments. The red mangrove tree, growing in marshy places, rises from a number of roots, which appear several feet above ground, before they are joined together to form the main trunk, which is generally tall and large, hard, and good for building; and numerous ligneous shoots, without leaves or branches, descend from the stem and the lateral boughs towards the ground, where they take root, and like props or pillars, afford support to the tree in its watery soil. The cocoa nut tree, growing to the height of 60 or 80 feet, but seldom perfectly straight, bears fruit at the age of six or eight years. The pipeira tree, about 70 feet high, and 9 in circumference, affords a weighty durable timber, and bears a small round fruit of a farinaceous nature, which is sometimes used by the Indians as food. Among a variety of other valuable forest trees, growing to the height of 50 feet, may be mentioned the iron-wood tree, so called from its hard and heavy wood, which is used for clubs, wind-mills, and similar purposes; the bullet-tree, which has a dark coloured wood, spotted with small white specks, very durable, and so weighty as to sink in salt water; the launa tree, which bears a fruit like an apple, yielding a purple coloured juice, employed by the Indians in painting their bodies; the mahogany tree, resembling the cedar, and preferring a rocky soil; the tonquin bean tree, which bears the sweet-smelling pulse of that name, and some of which sometimes grow to the height of 70 or 80 feet; the cassia fistula, covered with a light brown bark, and bearing pods 18 inches long, containing a sweet pulp resembling treacle. Of a smaller size are the bourracoura, or letter wood tree, which contains a heart of a deep red colour, marked with black spots, hard, ponderous, capable of the finest polish, and highly valued for its beauty; the hiarree tree, which grows near rivers, and generally at a distance from other trees, esteemed a strong poison, even the smoke of the wood when burning proving fatal to animal life; the cocoa tree, which bears a pod of the size and shape of a melon, containing rows of nuts in its longitudinal cavities.

The most valuable fruit trees are, the guava, which bears a round fruit of a light yellow colour, the internal part of which is a red pulp generally made into jellies, and the external part resembling the substance of an apple, employed in tarts, &c.; the tamarind tree, which grows to a considerable size, and produces its fruit in a large pod; the aviato or avogato pear tree, resembling a walnut tree, and bearing a delicious fruit like a large pear, of a pale green colour, and yellow pulp, similar in taste and flavour to the finest peach; the female poppau, which produces an oval-shaped fruit, about six inches in length; plantains, bananas, pine apples, &c. Among the useful shrubs, we can only particularize the cotton bush, which produces two crops annually; the coffee bush, which also bears two crops, each tree yielding about a pound and a half at a crop; the palma christi, or castor bush, which bears nuts of a triangular form, covered with a thin brown fur, the kernels of which yield by expression the well known castor oil; the cassava shrub, of which the roots are ground into meal, and formed into an excellent bread; but the bitter cassava, though it becomes a wholesome food when boiled or baked, is in its raw state a fatal poison. Of many curious plants may be mentioned the aloe, of which there are various kinds; the caruna shrub, bearing a nut, of which the kernel is used by the Indians as a slow poison; the curretta, or silk-grass plant, a species of aloe, the leaves of which contain a saponaceous pulp, used in washing, mixed with fine and strong white filaments, which, when properly cleaned, can scarcely be distinguished from threads of silk, and are employed in making nets, cords, &c.; the siliqua hirsuta, a slender creeping plant like the vine, bearing pods resembling the common pea, covered with fine stiff pointed hairs, which, upon being applied to the skin, produce an intolerable sensation of itching; troolies, or leaves of an enormous size, from 20 to 30 feet in length, and about 2 or 3 in breadth, growing from a short root close to the ground, and used as a thatch for houses, which they protect from the heaviest rains, and last for many years; nibbees, a kind of ligneous rope, without any foliage, growing to an immense length, and from 3 to 18 inches in circumference, sometimes entwining themselves together to the thickness of a ship's cable, and at other times interweaving themselves like nets, so as to intercept the game in their course, frequently climbing to the tops of the loftiest trees, and again descending to take root in the earth, often coiling themselves so closely around the trunks of the trees, as completely to check their growth, and so extremely tough as to be used by the natives for fastening the posts and thatch of their huts. The roots most deserving of notice, are the ipecacuanha, the ginger, and the Indian yam, which last is about eight inches in length, and six in circumference, of a reddish purple colour, and affords an agreeable farinaceous food..

The native animals of Guiana are not yet fully ascertained; and its unexplored forests contain, in all probability, many animated beings, which are but very imperfectly known to the zoologist. Many of the domestic animals, the bull, the cow, the ass, the hog, the sheep, &c. have been imported from the old continent; and some of these, having escaped into the woods, have run wild and multiplied rapidly. Most of them, however, have greatly degenerated both in size and in flesh, in consequence, it is conjectured, of the perpetual perspiration to which they are exposed, and the coarseness of the grass on which they feed. The sheep, particularly, are remarkably diminutive, and their wool converted into straight hair. The hogs, on the contrary, are large and fat, and superior to those of Europe. The goats are large and beautiful animals, common in all parts of the country; often kept on the plantations, where they breed quickly, and yield much milk. The poultry are as plentiful and excellent as in any part of the world. A smaller species of domestic hen, with rumpled or inverted feathers, is reared by the natives in the inland parts of the country, and is considered as natural to Guiana.

The beasts of prey, which abound in the forests of this country, though numerous, are not remarkably formidable to the human race. The most powerful is the tiger, of which there are several kinds; the jaguar, which resembles the African species, and sometimes measures six feet from the nose to the root of the tail, is very strong and ferocious, frequently attacking the cows, horses, and young negroes on the plantations; the couquar, or red tiger, resembling a grey hound in shape, but larger in size, and equally fierce as the last mentioned; and the tiger cat, a beautiful creature, not much larger than the domestic cat of Europe, but destructive and untameable like the rest of its kind. This is a ferocious little creature, called the crabbo-dago, not much larger than a common cat, and supposed to be the same with what Buffon calls the grison or grey weasel, which is never glutted with blood, but murders whatever comes in its way, whether quadrupeds, fowls or reptiles, if it is able to vanquish them. There are various kinds of monkeys, but no apes in Guiana. The natives affirm, that the ouran-outang, five feet in height, is found in the woods, but no European has ever seen any of these animals in the country. Of the others, the most remarkable are, the quato, which has a naked face, a nose like that of a negro, deeply sunken eyes, large ears, and, excepting its long tail, beais a great resemblance to the human form; the howling baboon, which is about the size of a small bull dog, has a long black beard, and is chiefly remarkable for assembling in large crowds, and uttering a most disagreeable howl or yell, which is continued for a long time, and which is said to be a sure sign of approaching rain; and the saccawinkee, or schacomingky, sometimes called the lion monkey, a small and delicate creature, only about five or six ounces in weight, which perches like a bird upon the forefinger, and is frequently brought down to the plantations by the natives for sale, has a small head, round smooth ears, oval face covered with fine white hair, a tail much longer than its body, long bushy black hair, especially around its neck, like the mane of a lion, is extremely susceptible of cold, and though frequently tamed, seldom lives longer than a few months. The coatimondi or Brasilian weasel, shaped like a dog, often as large as a fox, and resembling that animal in cunning, is a great destroyer of the poultry: and, equalling the monkies in the faculty of climbing trees, commits great ravages among bird nests. One of the most extraordinary animals in Guiana is the great ant-bear, which often weighs from 150 to 200 lbs. and measures not less than eight feet from the snout to the tip of the tail. It has a small head, covered with hair as soft as velvet, and a tail immensely large, flat, and covered with long hair like that of a horse, and as strong as the bristles of a hog, with which, during a shower, or when attacked, or when asleep, he protects his whole body. His feet are armed with long claws, with which he can defend himself against any dog, and even against the tiger, and never quits his hold while he has life. He has a long slender tongue, resembling a worm, sometimes almost two feet in length, and moistened with saliva of a sweetish taste, which he thrusts into the ants' nests, who settle upon it in crowds, when he draws it into his mouth, renewing the operation till no more are to be found. There are found in Guiana the porcupine, the armadillo, the sloth, several kinds of opossum, wood rats, and hedge-hogs.

There are two kinds of deer, the largest of which, called bajew, are about the size of an English buck, and feed in great numbers, in the savannahs; the smaller species, called wirrebocerra, are remarkably nimble, have no horns, and make the most delicate venison. The paccarara, or Indian coney, is common in all parts of Guiana, and greatly resembles the hare in shape and size; is very prolific, and easily taken; and its flesh, which is much like that of a rabbit, forms a principal part of the food of the natives. There are several kinds of wild hogs in the forests, particularly the pingos, or warree, resembling small English hogs, found in herds of 300 or more, running always in a line, and easily knocked on the head. A larger kind, called craspingos, are armed with strong tusks, and, when wounded or obstructed in their course, become extremely ferocious. But both these kinds are supposed to be merely the domestic hog of Africa or Europe in a wild state; and the only species indigenous in Guiana, is the piccaree, or Mexican hog, which is about 3 feet in length, without either tusks or tail, and is particularly remarkable, from having on its back, above the hind legs, a cavity about an inch deep, filled with a white fetid fluid, which, unless cut out as soon as the animal is killed, infects the whole flesh, so as to render it unfit for being used as food. They are found in large herds in the drier and mountainous parts of the country; and their flesh is greatly admired by the natives. There is a great variety of lizzards, of which the most remarkable is the guana, about three feet in length, and generally found among the shrubs and fruit trees. Its eggs, which are deposited in the sand, are reckoned excellent food; and its flesh particularly is esteemed a great delicacy, resembling in taste that of a chicken.

The amphibious animals are very abundant in Guiana; of which we can only slightly notice the tapira, resembling the hippopotamus, but not larger than an ass, with the head of a horse, and a considerable prolongation of the upper lip, excessively thick skin, bristly mane, and short tail, feeds on grass and aquatic herbs, and its flesh is accounted superior to the finest ox beef, but it is rarely procured, as the animal is extremely shy, and plunges into the water upon the least alarm; the manatee, or sea cow, about 16 feet or more in length, with a head like that of a hog, nostrils like an ox, breasts like those of a woman, and a tail like that of a whale, seldom quits the water entirely, and its flesh, which is very fat, tastes much like veal; the alligator, or cayman, found sometimes 20 feet in length, but generally harmless, and even in water seldom attacking a man, as long as he keeps himself in motion; the laubba, which seems to be the same with what others call the paca, or spotted cavey, or aquatic hare, is peculiar to this part of the world, about the size of a sucking pig or large cat, with the head of a pug dog, extremely fat, and resembles the finest pork, feeds on herbs and grain, takes refuge in the water when pursued, swimming a long time at a short distance from the surface, so that it is often shot under water with arrows; the pipa, a kind of toad or frog, sometimes as large as an ordinary duck, a creature of a hideous appearance, covered with a brown shrivelled skin, and chiefly remarkable for the uncommon loudness of its voice; but still more for the peculiar manner of its propagation, the young being hatched in watery cells on the back of the female, or, according to others, placed there by the assistance of the male after they have become tadpoles, and continuing to nestle there till the second transformation is completed.

There are many snakes in Guiana, of which the best known are the rattle-snake, whip-snake and dipsas; the papaw, or ammodytes, a harmless and beautiful creature, from three to five feet in length, which is revered by the natives as a sacred object; the oroocookoo, supposed to be the same with the small laboia, the bite of which has been known to prove fatal in a few minutes; and the aboma, an amphibious animal, delighting in low marshy places, found upwards of 20 feet in length, and said when fully grown to be from 30 to 40 feet long, and from 3 to 4 in circumference at the thickest part of the body. Its bite is not considered as venomous, and it is a sluggish unwieldy creature, but seizes its prey by surprise, and devours deer, hogs, or even the tyger, without difficulty, entangling and crushing them in its grasp, besmearing them with saliva, and swallowing their bodies entire.

The birds most commonly found in Guiana are, the vulture, eagle, owl, falcon, butcher bird; parrots of various kinds; large and beautiful mackaws, some of which are about the size of a capon, toucan, pelican, wood-pecker, green sparrow, tiger bird, a kind of heron of a reddish colour, spotted with black; flamingo, found in flocks on the banks of rivers, and so tame as frequently to mix with the poultry on the plantations; agame, or trumpeter, a kind of turkey peculiar to the country, and often domesticated; sun-bird, resembling the English partridge, and sometimes kept in the houses to destroy the ants; peacock-pheasant, or powese, resembling in size and flavour an English turkey; kishee-kishee, about the size of a sparrow, adorned with most beautiful plumage, and sometimes brought by the Indians from the interior of the country; the mocking bird, which hangs its nest, (about 14 inches in length, and 8 in circumference,) at the extremity of the twigs of the remotest branches, as a security from the monkies; and the humming bird, which is found here in great number and variety: the most common of these, of a green and crimson colour, is not bigger than a large cherry, and the smallest, of a black and green colour, with a golden tuft on its head, nearly a third less than the last mentioned, sometimes weighs little more than 50 grains. There are bats of a large size, some of which have been found to measure thirty-two inches between the tips of the extended wings, and which are known to open the veins in the feet of persons asleep, and to suck the blood till they are satisfied.

The fish caught on the coast are far from being delicate, as the water is extremely muddy for several leagues from the shore. The most remarkable of the salt water fish is the low-low, about six inches in length, and three in circumference; and the largest of the fresh water fish is the barroketa, about three feet long, and two in circumference, resembling a salmon, white, fat, and delicate. The peri, another fresh water fish, about 18 inches long, and of a flat form, has a large mouth armed with long sharp teeth, and is said to attack persons when bathing in the rivers. The frog fish is one of the greatest curiosities in Guiana, and is said to pass by regular gradations, through the form of a frog, a frog fish, and lastly a fish, but is affirmed by Stedman to proceed rather in the opposite direction, from a fish to a frog, and to be probably nothing else than a kind of tadpole, which grows to a large size before undergoing its usual transformation; in the fish state, it is about eight or ten inches long, without scales, and exceedingly fat and delicate. The galvanic eel is very common in the rivers of this country, generally about three feet in length, and 12 inches in circumference, though sometimes found of a much larger size; it comes frequently to the surface of the water, as if to inhale the air, and its flesh is esteemed delicate food by the natives. Multitudes of crabs are found in the bottoms of the muddy streams; and a large land crab, much used as food by the natives, abounds on the banks of the sea, at the mouth of the rivers.

Insects abound in Guiana in vast numbers, owing to the continued warmth of the climate, which both favours their production, and prolongs their existence; and continually flying in the faces, or crawling about the bodies of the inhabitants, are the most intolerable pest of the country, especially to new settlers from Europe. Musquitoes are inconceivably numerous during the rainy season, particularly on the coast, and on the banks of rivers; and are said to prevail most in places, which are in a state of progress from a wild to a completely cultivated condition. The juice of lemons or limes mixed with water, and applied to the skin, is at once the best remedy for their stings, and a tolerable preservative against their attacks. Cock-roaches are found from one to two inches in length, which make their way into chests and boxes, and besides destroying cloths of every description, render every kind of victuals which they attack utterly disgusting, by the nauseous smell which they leave behind. As this creature is seldom seen to fly, the best preservative against its ravages is to place the boxes or trunks upon empty wine bottles, kept free from dust, so as by their smoothness to render its ascent more difficult. Ants of many different kinds are extremely numerous, and prove very destructive to the stores, (especially of sugar,) in the plantations. Their immense nests of black earth, built on the trunks of the trees, are often so high as to resemble large black bears at a distance; and some of their hillocks on the ground have been seen as high as 15 or 20 feet, and nearly 100 feet in circumference. Some of these insects are above an inch in length, and cause great pain by their bite. A small species, called the fire-ant, which flies in great numbers, occasions a burning sensation resembling that produced by boiling water, supposed to proceed from some venomous fluid injected into the wound. There are two kinds of fire-flies, the smallest of which, seen only during night, emits sparks of fire at intervals; but the larger kind, which is more than an inch in length, affords so steady and clear a light, that two or three of them put into a glass will enable a person to read or write without difficulty. The bees of Guiana are very small, of a black colour, and armed with powerful stings; and one species, mentioned by Stedman, which builds its nest in the roofs of houses, is said to attack every stranger with the greatest fury, while it never molests the regular occupiers of the habitation in which it has taken up its abode. The grasshopper tribe is sufficiently numerous; but two kinds are peculiarly worthy of notice, one called "the walking leaf," from its wings, about three inches in length, being so folded on its back, as to give it a close resemblance to a brown leaf; the other, called in Surinam "Spaanse-juffer," has a body about seven inches in length, not thicker than a common quill; has no wings, but is mounted like a spider on six legs, nearly six inches long, and has on its head four antennæ, two of which are about five inches in length. An enormous and hideous looking spider, called the bush-spider, is found in the forests; and is of such a size, that one of them, when put into a case bottle eight inches high, actually reached the top with some of its claws, while its feet were resting on the bottom. It feeds upon all kinds of insects, and is said even to suck the blood of young birds. Its bite is so venomous, as to be supposed to prove sometimes fatal, and always at least occasions a fever. The groe-groe, or palm-tree worm, about three inches long, and thick as a man's thumb, of a light yellow colour, with a black head, breeds in the cabbage tree after it is cut down, is roasted, and eaten as a great delicacy, equal to the finest marrow; and sometimes its fat, melted and clarified, is used instead of butter. There are centipedes above six inches in length, which move with equal rapidity backwards or forwards, and whose bite is venomous. Scorpions, also, are frequently found among old trees and rubbish; but their sting, though very painful, and apt to occasion fever, is said not to be mortal.

For an account of the native human inhabitants of this country, we refer to the general description of the Amecan Indians, given under the article America; and shall only notice here, in a cursory manner, the particular tribes which occupy the interior of Guiana, but occasionally visit the European settlements on the coast. The chief of these are the Caribs, Accawaws, Arrowawcs, and Worrows. The Caribs inhabit that part of the coast which lies between the Essequebo and the Orinoco, and are by far the most numerous, warlike, and active of the natives. Their stature is taller, their complexion lighter, and their features more sprightly and agreeable than those of the other tribes. They are also more industrious, and, besides the ordinary Indian occupations of hunting and fishing, they cultivate fields of plaintains and cassava around their dwellings. They carry on constant hostilities against the Spaniards; but are considered as allies of the Dutch. They frequently go to war also with the other tribes; and, in some instances, have been known to devour their enemies slain in battle. The Accawaws inhabit the inland districts behind the Caribs, and adjacent to the sources of the Essequebo, Demerary, and Berbice. They bear a nearer resemblance in their persons to the Caribs than the other tribes; but are more grave in their aspect and manners, and remarkable for their superior cunning. They are also addicted, more than any of their neighbours, to the use of poison, both against their enemies, and those of their own people who may may have done them any injury. The Worrows occupy the coast between Demerary and Surinam, and are much darker in their colour, disagreeable in their aspect, and dirty in their habits, than any of the other tribes. They are said to be extremely pusillanimous and lazy, scarcely exerting themselves to provide any other clothing than the bark of trees, or to procure any better food than crabs and fresh water. The Arrowawcs reside behind the Worrows, at the back of the settlements of Surinam and Demerary, and are described as the most gentle in manners, lively in temper, and handsome in person, of all the Indians of Guiana. They are remarkably friendly to the Europeans, and peaceable in their intercourse with the other Indian nations. Besides these four tribes, who are most frequently seen at the settlements on the coast, other two have been mentioned, namely, the Taiiras, residing on the sea-coast between Surinam and the river Amazon, who are said to be extremely numerous, but peaceable and indolent, resembling very much the Worrow tribe; and the Piannacotaws, who live far inland, and are violent enemies to all Europeans, with whom they obstinately refuse to have any kind of intercourse. It has long been the policy of the Dutch settlements to cultivate the friendship of these native tribes; and an annual sum is expended in purchasing blue cloth, beads, hatchets, ribbons, and other ornaments and implements, as gifts to their Indian neighbours. They come down to the colonies occasionally in small parties, and make engagements to cut wood, an operation at which they are remarkably expert; but they soon become impatient of the restraint of regular industry; and sometimes take their departure suddenly, without any apparent reason. They frequently appear also as traders, bringing as their merchandize, cotton hammocks, canoes, baskets, wax, balsam of capivi, arnotto, wild nutmeg, wild cinnamon, parrots, monkeys, ebony, and other curious woods; for which they receive, in return, chequered cloth, fire-arms, gunpowder, hatchets, knives, scissars, looking-glasses, fish-hooks, combs, needles, pins, beads, &c. One of their favourite purchases is rum, which they swallow with eagerness till they become completely intoxicated; but it is generally observed, that one half of the party keep themselves sober to watch their drunken friends, who afterwards perform the office of guards in their turn. Sometimes they bring down the prisoners whom they have taken in war, and sell them as slaves; but these captives serve only for show, as they absolutely refuse to work; and, if treated harshly, particularly if beaten, they pine and languish, refusing even to take food, till they finally die of want or dejection. The native Indians have a strong dislike of the negroes, whom they regard with contempt as an inferior race, and are generally ready to render assistance to the colonists in suppressing insurrections among the slaves, or apprehending the runaways. It is strongly recommended that every inducement should be offered to encourage their intercourse with the settlements; and that fairs should be held, at certain fixed seasons, for their barter trade, which might thus be greatly increased, to the mutual advantage of both parties.

GUIDO. See Rheni.

GUILDFORD, a borough and market town of England, in Surrey. It is the county town, and is situated on the side of a considerable chalk hill on the east bank of the Wey. This river is crossed by a stone bridge of five arches, which was lately widened with brick, and the centre arch enlarged to allow barges to pass. The town is large and well built, and consists principally of one excellent and spacious street, which, from the declivity of its situation, is particularly striking to strangers. Guildford contains three parish churches. Trinity church is situated on the top of the hill, and on the south side of the high street. The foundation stone was laid in 1740, and it was completed in 1763. It is a handsome brick structure, 82 feet long, and 52½ broad. The tower, which is also of brick, is about 90 feet high, and contains eight bells. St Mary's church is a very rude and ancient building, consisting of chalk, flint, pebbles, and rubble stones, coarsely put together. St Nicholas's church, which stands on the west bank of the Wey, is an ancient building of chalk and stone. The other public buildings and institutions are, the hospital, the free grammar school, the town or guildhall, the theatre, and the gaol. The hospital, built in 1619, is a brick building, inclosing a quadrangular space of 66 feet broad, and 63 deep, with a noble tower gate, with four turrets, at its entrance. It was founded by George Abbot, archbishop of Canterbury, for the maintenance of a master, twelve brethren, and eight sisters. The free grammar school, built of brick and stone, was built in 1557, and is 65 feet long and 22 broad. The town or guildhall, is a spacious building, with a turret on the top. It was erected in 1683, and is 44 feet long. The hall was formerly used at the assizes; but in 1789, Lord Onslow and Lord Grantley purchased the Red Lion Inn, and on one part of the ground erected a room 40 feet long, 30 broad, and 20 high, in which the judges now sit. The theatre was built near this room a few years ago. The gaol, rebuilt of stone in 1765, is near St Mary's church. There is also here a charity school, a Roman Catholic chapel, and meeting houses for the Baptists, Presbyterians, and Quakers: a cold bath was erected at a house near the bridge, by Lord Grantley, in 1775. There is a fine circular race course about two miles east of the town. A plate of 100 guineas given by William III. and three subscription plates, exclusive of matches, are run for in Whitsun week. The castle of Guildford, one of the principal objects in the town, is situated about 300 yards southward of the high street. The keep is now the chief part that remains. It is a quadrangle, 47 feet by 45½, and 70 feet high. The walls are ten feet thick. On the west side of the keep may be seen the outer gate of the castle. The ruins occupy at present about five acres. In the chalky cliff on which the castle is situated, is a series of caverns. One of these caverns is 45 feet by 20 wide, and 9 feet high. This town formerly enjoyed a considerable share of the clothing trade; but a small part of it only remains. The trade of the place consists chiefly in sending timber and corn to London by the Wey, and in supplying the surrounding villages with their requisite merchandize. A direct communication has lately been made with Brighton and the coast of Sussex, by a turnpike road to Horsham, and a fund has been raised for joining the river Wey and the Arun, so as to form a navigable line from London to the sea at Little Hampton.

The town is supplied with water by means of an engine, which discharges it into a reservoir at the foot of Poyle hill, from which it is carried by pipes to the houses of the inhabitants.

The following is the population abstract for the borough for 1811.

| | |
|---|---|
| Inhabited houses | 495 |
| Number of families | 596 |
| Families employed in agriculture | 46 |
| Do. in trade and manufactures | 434 |
| Males | 1382 |
| Females | 1592 |
| Total population | 2974 |
| Increase since 1801 | 340 |

See the *Beauties of England and Wales*, vol. xiv. p. 251.

GUILLOTINE, is the name of an instrument of death, invented by Dr Guillotin of Lyons, a member of the National Assembly of France, and used during all the horrors of the French revolution. M. Louis, a celebrated surgeon in Paris, is said to have been rewarded with 2000 livres for a dissertation on the advantages of the guillotine; and the inventor himself suffered death by his own instrument in the reign of Robespierre.

The hands of the sufferer being tied behind his back, he is fixed to a plank standing vertically, not reaching higher than his neck. This plank is suddenly brought by machinery into a horizontal position, and moved below the loaded axe, which descends with a slanting edge, and severs the head from the body.

An instrument of a similar kind seems to have been first used at Halifax in Yorkshire. It was introduced into Scotland, under the name of the *Maiden*, by the Regent Morton, who accidentally saw it in use when passing through Halifax; and one of these instruments is still to be seen in Edinburgh, in the Museum of the Society of the Antiquaries of Scotland.

# GUINEA.

Guinea, is a maritime district in the south-west part of Africa, to which various limits are assigned by different nations. The Dutch consider it as extending from Cape Blanco, 21° North Lat. to Cape Lopez, in 1° South Lat. making Sierra Leona, in 8½° North Lat. the boundary between North and South Guinea. The Portuguese include, under the general name, the whole of the coast from Cape Ledo or Tagrin, 8° North Lat. to Cape Negro, 16° South Lat. making Cape Lopez the division between Upper and Lower Guinea. According to the French, Guinea lies betwixt Cabo Monte, 11½° West Long. and Cape Lopez; and, by the English, the tract between the mouth of the river Gambia, 12½°, and Cape Palmas, 4° North Lat. is called North Guinea; while South Guinea reaches from Cape Palmas to Cape Lopez. By the greater part of geographers, Upper Guinea is limited to that part of the coast which runs from east to west about 500 leagues, comprehending Sierra Leona, Malaguetta, or the Grain Coast, the Ivory Coast, the Gold Coast, the Slave Coast, and the kingdom of Benin. Of Lower Guinea, in the more confined application of the name, extending from the kingdom of Benin to Cape Lopez, very little is known except the line of coast; and we have only to refer our readers to the map of Africa in this work, for the names and situations of its principal districts. The southern division, between Cape Lopez and Cape Negro, has been explored, and occupied chiefly by the Portuguese; and its different countries, Angola, Benguela, Congo *Proper*, and Loango, are described under separate articles. It is to Upper Guinea, that our attention is at present to be directed, and particularly to that portion of it which is generally denominated Guinea Proper, comprehending the Ivory, Gold, and Slave Coasts. Benin has been already noticed; and Sierra Leona will form the subject of a distinct article.

The interior of the Grain country is very little known, and its line of coast may be described in a few words. It is sometimes called the Pepper Coast, and Malaguetta, from the long pepper of that name; but generally the Grain Coast, from the grain of paradise with which it abounds. It extends about 100 leagues from Cape Mesurado to the vicinity of Cape Palmas; and is in general low, flat, covered with forests, and watered by numerous streams.

The principal places along the coast, are Rio Junco, or Rio del Punto, about 50 miles east of Cape Mesurado, a shallow stream, about 500 paces broad at its entrance, flowing through a level and delightful tract of country, which is inhabited by a peaceable and industrious people, who are principally employed in making salt and cultivating rice, and who trade in cotton cloth, sea horse teeth, skins of wild beasts, and slaves;—the country of the Foljas, or Pholeys, a powerful tribe, who are noted for the superior elegance of their speech, and whose territories are partly watered by the Junco;—Tabo-Dragon, a large and populous village on the east bank of the Tabo, or Rio Corso, where the merchants of Dieppe established a factory;—Rio Sestos, about 50 miles from Rio Junco, said to be navigable by small barks for 25 miles, has several villages at its mouth and on its banks; and the inhabitants, called Quabo-monou, are a pacific and well-proportioned race, subsisting on millet, fruits, and fish;—Sanguin, Baffa, Setuna, Batoua, Cape Sino, Sestrokrou, Wappo, Great Sestro, &c. all villages along the coast, of which the last mentioned is the most populous, and most noted for its trade in pepper and ivory, and is situated near Rio des Escravas. The Grain Coast is generally bordered with shoals; and its staple commodities are long pepper, leather, ivory, gold-dust, and slaves.

The Ivory Coast extends about 110 leagues from west to east, from Cape Palmas to Cape Apollonia, in a low strait line, with few bays or islands; but a foul bottom and high surf prevent vessels from anchoring or landing upon any part of it with safety. Cape Palmas, formed by two hills covered with palms, in 4° 25′ North Lat. and 12° East Long. has a small gulf behind it, where vessels may be sheltered from the south wind. Grova, a few miles eastward of Cape Palmas; Tabo-Duno, where there is a commodious road for shipping; Drevin Petri, a considerable village about 50 leagues east of Cape Palmas; Giron, on the border of a well watered meadow; Lahou, a populous town frequented by Europeans, and abounding in provisions, and from which, eastward to Cape Apollonia, the coast is commonly called the country of the Quaquas; Gammo, a place to which the inhabitants of the interior bring down their articles of traffic; Sueiro d'Acosta, where there is a small road for ships; Issini, where the French built a fort at the beginning of the 18th century; Assoka, about five or six miles from the sea coast, and said to contain about 1000 inhabitants; Albiani and Tabo, environed with plantations of palm trees; Akani Mina, in the vicinity of Cape Apollonia, are the principal villages on the coast, and most of them are situated on the borders of rivers. The soil of the lower and maritime tracts produces cotton, indigo, cocoa nuts, fruit, rice, and other grain. The chief articles of trade are gold, ivory, salt, cotton, palm-wine, and oil. All sorts of tame animals abound in the country; and immense numbers of elephants, tigers, panthers, serpents, &c. are found in the forests. This level coast is bounded by mountains well covered with wood, and where the vallies are generally fertile and populous.

The Gold Coast commences a few leagues westward of Cape Apollonia, and terminates at Rio Volta, an extent of about 350 miles, lying between 4° 40′, and 5° 40′ of north lat. and between the meridian and 3° west long. Cape Apollonia is low on the coast, but rises into three hills, covered with trees, and seen from a great distance at sea. The first fort on the windward part is Apollonia, about three miles eastward of the Cape, situated in a spacious plain, which is bounded towards the interior by a fine lake of fresh water, about six miles in circumference, and full of fish. In this lake a small village is erected on wooden piles, the inhabitants of which are said to have been exiles from the interior, who were not allowed to build upon the land. Along the whole coast of Apollonia, the surf is exceedingly dangerous, and there are no creeks or harbours. This territory or state extends about 100 miles along the coast, and probably not more than 20 inland. The next settlement is Axim, which belongs to the Dutch, and forms part of the extensive and fertile country of Ahantah. The fort, originally built by the Portuguese, and called Fort Anthony, stands upon a promontory, which forms the western part of Cape Three Points. The landing is here perfectly safe, and may be approached by boats in the dry season without any danger. About four leagues from Fort Anthony is Fort Fredericksburgh, first erected by the Prussians, but afterwards sold to the Dutch, and now in ruins. At three leagues distance is Accoda, another Dutch settlement; and three leagues farther is Dix Cove, belonging to the British, advantageously situated at the entrance of a small cove, which is capable of admitting vessels of 40 tons at high water. Boutry, Taccorary, and Succondee, all Dutch settlements, lie at the distance of a few miles from each other; and the last mentioned forms the extremity of the Ahanta country, which is the richest and best provided with harbours of all the Gold Coast. It stretches farther inland than Apollonia, and is bounded by the Warsaw and Dinkara states. About three leagues from Succondee is Chamah, where the Dutch have a small fort called Sebastian, supposed to have been originally built by the Portuguese. About eight miles from Chaman, is Commenda, where the British and Dutch have settlements and forts, and where the inhabitants are chiefly employed in supplying vessels with canoes and canoe-men for trading on the leeward coast. About 9 miles from Commenda, is Elmina, the most respectable fortress on the Gold Coast, and the head-quarters of the Dutch settlements. The town is large, and some of the houses built of stone. The river admits vessels of 100 tons at high water, which can unload under the walls of the castle. The inhabitants consist of traders, fishermen, and a few mulatto mechanics. The population amounts to about 15,000; and a considerable trade is carried on, particularly in gold and slaves. About 9 miles from Elmina, is Cape Coast Castle, the principal British fort and settlement on the Gold Coast. It was built by the Portuguese, who ceded it to the Dutch, from whom it was taken in 1665. It has been considerably improved and strengthened by the African Company; and the castle is capable of making a powerful resistance on the side towards the sea. The town is irregular, and the houses chiefly built of clay. The population amounts to 8000; and the trade consists chiefly in gold. The adjoining country is called Fetu, and is subject to the Fantee state. During the existence of the slave trade, the countries from Cape Coast to Acra were the great centre of that nefarious traffic, which brought a rapid accumulation of wealth to the native traders in every town and village, the result of which was a spirit of idleness, licentiousness, and turbulence, which threatened the overthrow of all order and security in the settlement. About four miles from Cape Coast, is a Dutch fort called Nassau, situated at a village named Mouree. About six miles from Mouree, is the British fort Anamaboa, the most compact and best built in the country; and the town in its former flourishing state contained at least 15,000 inhabitants. But it was destroyed in a war with the Ashantees, a powerful people in the interior; and the abolition of the slave trade, in which it formerly bore a principal share, is likely to retard its re-establishment. About three miles from Anamaboa is the town of Cormantine, where the Dutch have a fort called Amsterdam, originally built by the British, and the first that was erected on the Gold Coast. About six leagues eastward is Tantumquerry, where landing is very difficult; and, nine miles farther, is the district of Assam or Apang, where the Dutch have a small fort, and where the coast is more accessible. About 8 miles from Assam is the town of Winnebah, where there is a small fort belonging to tho British, and where the landing is generally safe. The town has been reduced, by wars and other casualties, from a population of 4000 to 2000, and was formerly a part of the Agoona country, which has recently fallen under the power of the Fantees. About three leagues from Winnebah is the Dutch fort of Berracoe; and nine leagues farther west is Acra, where there are settlements of the British, Dutch, and Danes. Acra, is an independent state, which formerly belonged to the kings of Aquamboe, but has at present most intercourse with the Ashantees. It is the most healthy situation on the Gold Coast; and the inhabitants are more civilized than most of their neighbours. About 32 miles from Acra, is a small British fort named Pram Pram; and 8 miles farther, is the Danish fort of Ningo, around which the country is level and fertile, abounding in game, and in a large breed of horned cattle. About 36 miles from Ningo is Adda, where there is a Danish fort, and is situated on the left bank of the Rio Volta, which terminates the Gold Coast. This river runs nearly north-west and south-east, separating the countries of Aquamboe and Aquapim, and is navigable for small craft to the distance of 100 miles from its mouth. See Acra, Anamaboa, and Aquamboe.

The slave coast extends from Rio Volta to Rio Sagos, which separates it from the kingdom of Benin. It reaches about 50 leagues from west to east, and contains the following districts or provinces: Koto, lying between Rio Volta and Cape Monte, which is a flat, sandy territory, little frequented. Near Cape Pucalo, is a village named Quilta, where there is a British fort; and at a little distance is Koto, the capital of the country. Popo or Papa, about 10 leagues in length, between Cape Monte and Juida, is low and sandy, in some places marshy, and generally inaccessible on the coast. At the mouth of the Tari, is a village of the same name, and a Dutch factory. Juida or Whidah, extending several leagues, is more fertile and populous than the districts already noticed; and at the mouth of one of its rivers, called Euphrates, is a port where ships may unload, though not without considerable inconvenience from the surf. Near this river, but about two leagues from the shore, is a populous town, named Sabi or Xavier, where merchants resort. At the mouth of another river, named Jaquin, are British, Portuguese, and Dutch settlements, in an island called Gregoi. Ardra extends about 15 leagues along the coast, and is a fertile but insalubrious tract. Foulaon, Assem, Jago, and Appak, are the names of its principal villages. Whidah and Ardrah have been long subject to the king of Dahomy, a powerful state in the interior. The principal trade of the slave coast consists in salt, palm-oil, and slaves. See Ardrah and Dahomy.

There are several tracts along the coast of Guinea of a sandy and sterile nature, without any other trees than the palm; but the general appearance of the country from the sea is that of an immense forest, with a few high grounds covered with lofty trees, and the thickest underwood. Many of the vallies are richly planted, and extensive plains may be seen, beautifully studded with natural clumps of trees and bushes. In the more inland parts, where the moisture is more abundant than on the coast, the woods are almost impenetrable, on account of their luxuriant growth; and the surface of the ground is completely concealed by shrubs and herbs. The rivers generally run in a very winding direction, and in some places overflow their banks during the wet season, forming large stagnant ponds.

The soil varies considerably along the coast, from a light sand or gravel, to a fine black mould and loamy clay; but it is more uniformly rich and productive towards the interior of the country. For the space of six or eight miles from the sea may be found soil of every description, suited to every kind of cultivation.

The climate is not so hot as in many other parts of Africa, nearer the tropics; and it is generally observed that the countries on the equator, from five to six degrees on either side of it, are the most temperate in the tropical regions of Africa. The temperature is found in these countries to be affected, not merely by the latitude, but by various other causes; and is always cooler where the soil is good, cultivation extensive, and the country open, with high lands in the vicinity. At Cape Coast, though accounted the hottest situation on the Gold Coast, the thermometer is usually, during the hottest months, from 85 to 90 degrees of Fahrenheit. At Winnebah and Acra, it is seldom known to exceed 87; and, during the months of June, July, August, not higher than 78 degrees.

The seasons, as in other tropical countries, may be distinguished into wet and dry; or rather into two wet and one dry period. The first wet season commences in the end of May, or beginning of June, when the rains fall with great violence, and without intermission for several days. Strong breezes commonly follow this first deluge, and the rains are seldom very heavy during the remainder of the wet season, which terminates with the month of July. Then begins the foggy season, which is extremely unhealthy, especially in low, swampy, or woody situations, and continues for two or three weeks. About the month of October, the second rainy season begins; but the rains do not fall with so much violence as the first, nor are they succeeded by mists and foggy weather. The dry season begins with November, and continues during the remainder of the year to the month of May; but, in the course of this period, the coast is visited with violent storms of wind, generally denominated tornadoes and harmattans. Tornadoes* commonly commence in March, and cease with the beginning of the first rains; but sometimes blow before or after the second rains, or preceding a harmattan. They invariably come from the eastward, and are generally experienced a day or two after the full and change of the moon. Their approach is sufficiently indicated by vivid and successive flashes of lightning in the east, attended with thunder and heavy clouds, and by the clear and bluish appearance of the horizon. Their nearer approach is announced by the darkening of the horizon, especially in the eastern hemisphere, the increase of the lightning, and, finally, as an immediate prelude to the tempest, by a solemn stillness and entire calm in the lower part of the atmosphere, while the upper regions appear in dreadful commotion. A gentle air is then perceived, which is almost instantaneously succeeded by violent gusts of wind, usually accompanied with rain, and seldom continuing above half an hour or fifty minutes. Tremendous peals of thunder, and torrents of rain, for the space of two or more hours, terminate the storm. During its continuance, the thermometer suffers a rapid depression of five degrees or more; the air is subsequently cooled, vegetation refreshed, and the human

* The name *tornadoe* is supposed to be a corruption of the Portuguese word *trevado*, a thunder storm.

constitution invigorated. A harmattan* is an easterly wind, which prevails in the months of December, January, and February, along the coast from Cape Verd and Cape Lopez. It comes on indiscriminately at any time of the day, or of the tide, or of the moon; and continues, sometimes one or two days, sometimes five or six, and sometimes even fifteen or sixteen. It is always accompanied by a fog or haze, which occasions a considerable obscurity, and renders the sun, which appears only a few hours about noon, of a mild red colour. Extreme dryness is another attendant of a harmattan, and, during its continuance, no moisture is perceived in the atmosphere, or any falling of dew on the earth. All vegetation is checked, and the more tender plants are completely destroyed. The grass becomes like hay, and the most vigorous evergreens droop under its influence. Its parching effects are severely felt on the external parts of the body, particularly the eyes, nostrils, lips, and palate, which become dry and uneasy. Drink is often required, not so much to quench thirst, as to remove a painful aridity in the fauces; and, though the air is cool, a troublesome sensation of prickly heat is felt on the skin. If the wind should continue for four or five days, the scarf-skin generally peels off from the hands and face, and even from the whole of the body. Notwithstanding these disagreeable effects, it is found, on the coast of Guinea, to be highly conducive to health, restoring persons labouring under dysenteries, fevers, or any debilitating evacuations, arresting the progress of epidemics, and apparently preventing even the artificial communication of infection.†

The principal vegetable productions of the coast of Guinea, are maize, millet, rice, yams, cassada, potatoes, pulse, plantains, guavas, bananas, chillees, &c. The sugar cane grows spontaneously, to a tolerable size; and the cotton shrub is found in a wild state. The indigo plant is common in many parts of the coast; and black pepper has been discovered in the inland districts. European cabbage and eschallots are cultivated in some places; and a mucilaginous vegetable, called *encrumah*, the same as the ockra of the West Indies, (*Helescus esculentus*,) is very plentiful in the country. Besides the ordinary tropical fruits, there is one of a very nutritious nature, called *enteraba*, which is much used, and is about the shape and size of the largest onions. The silk-cotton tree is found in every part of the coast, and grows to a majestic size, so as to furnish excellent materials for the formation of canoes. There is a great variety of useful timber in the country, but the palm-tree is the most profitable to the natives. Of the leaf they make rope, thread, nets, fishing lines, &c. From the fruit they express an oil of great delicacy, which is used in all their dishes, and, when eaten fresh, is equal to excellent butter. The kernel contains a hard pulpy substance, which is sometimes roasted and eaten by the women, as promoting corpulency. From the trunk of the tallest species, which sometimes reach 100 feet in height, they draw an intoxicating liquid, which they call palm-wine, and which is procured by inserting a reed into a hole at the top of the tree, through which the liquor flows into an earthen pot. A similar liquid, of a more agreeable flavour, and less intoxicating quality, is procured from the low-palm; but, in order to procure it, the tree is generally dug up, and the trunk heated by fire, that the juice may flow more abundantly. This wine is drunk in a state of effervescence, and will not keep above a few hours.

The mountains of Guinea, as far as they have been examined, are in general granitic and schistous, and are filled with mines of gold and iron. The latter of these metals is little known to the natives, and Europeans have not thought it their interest to instruct them in the subject; but the first has been sought from time immemorial, and is likely to become a still more extensive object of traffic, in proportion as the exportation of human beings shall cease. Gold is found in these mountains in a primitive state, between two layers of a granite, finer, more solid, and more highly coloured than the rest of the rock; but the natives, unacquainted with the art of mining, and unprovided with proper tools for the purpose, have never attempted to work it in these places. They confine their operations to digging at the base of the mountains, where the schistous beds and banks of granite are more friable, and washing the sands in the beds of rivers and water courses at the bottom of the hills, when the rain water has run off. In digging, they work downwards, as if forming a well; or sometimes make a ditch about 20 or 30 feet deep, till they become alarmed for the crumbling down of the earth. They generally begin to find the gold at the depth of three feet; and, as they advance in the work, put the lumps of the metal into pouches which are fixed round their waists. Pieces are sometimes found of a considerable size, and the king of Ashantee is said to possess a lump of native gold, so large that four men are required to lift it. The earth, which is thrown out in the course of the digging, is laid in heaps at the side of the pit, and is carried by other labourers, chiefly women and children, to the nearest river, where it is washed in bags or wooden bowls, and the particles of gold afterwards separated from the heavier parts which remain in the vessel. This ore is sometimes so rich, that a piece of it, weighing four or five ounces, has been known, when pounded and washed, to produce about four pennyweights of gold dust; and the general fertility of the mines may be estimated, from the circumstance of the slaves employed by the king of Ashantee in 1790 engaging to supply him with half an ounce a-day for each labourer. The gold-finders, who wash the sands on the banks of rivers, and the sea-shore, are less successful in their researches, and it is generally the women only who are thus employed; but this precious metal, it is sufficiently ascertained, is very abundant in the interior of the country, and the mines may be considered as still virgin mines.

The animals of Guinea are numerous, but only such as are common to the western coast of Africa. The ordinary domestic animals, dogs, cats, sheep, goats, and hogs, are plentiful in most places; and poultry, particularly is found in great abundance. There are horned cattle in some parts of the coast, especially in Apollonia, but only in the possession of the chiefs. The wild animals are buffaloes, tiger cats, leopards, hyænas, jackals, ant-bears, porcupines, monkeys, deer, hares, squirrels, musk-cats, alligators, lizards, land-crabs, chameleons, guanos, scorpions, centipedes, and a variety of snakes. The hippopotamus is occasionally seen on the banks of the river Volta. The feathered tribe in a wild state are extremely various; and the smaller birds, particularly, are remarkable for the beauty of their plumage. The lakes and rivers abound with mullet and other kinds of fish; oysters and prawns are plentiful in some places; and turtles are not uncommon. There is a variety of excellent fish on the coast, which is procured in abundance during the dry season, when the surf is least violent.

* Supposed to be a Fantee word, pronounced by the natives *harmanta*, and said by them to signify a cold dry wind.

† It appears to be the same kind of wind as the *sammiel* of Egypt, and the *sirocco* of the Mediterranean.

There are several distinct nations along the coast of Guinea; but their general customs are so extremely similar, that they may be described as one people. The most powerful tribes are found in the interior of the country, and they are, in many respects, superior to those who inhabit the maritime districts. The two most extensive of these kingdoms are Dahomy (see Dahomy) and Ashantee, both of which have made their power at times severely felt on the coast. The former is described in a preceding article; but very little was known of the latter, till its king appeared on the coast, in a war against the Fantees in 1807; when the discipline and bravery of the army, and the order and regularity of the court, evinced a considerable degree of civilization. The following account of an interview between the governor of the British fort at Annamaboe and the king may furnish some idea of this people. "The governor was obliged to visit each man of rank, before he could be received by the king; a ceremony that could not be prudently denied, and which occupied some time; for those men had their several courts, and collectively had formed an extensive circle. Every one of them was seated under a huge umbrella, surrounded by attendants and guards, with young persons employed in fanning the air, and dispersing the flies." "After the ceremony of visiting those persons was over, the governor was conducted towards the king, who was surrounded by a number of attendants, whose appearance bore evident marks of riches and authority. Chairs, stools, axes, swords, flutes, message-canes, &c. were either of solid gold, or richly adorned with that metal. Those dazzling appearances, added to damask, taffety, and other rich dresses, gave a splendour to the scene, highly interesting. When the governor approached the king, and when an interchange of compliments had passed, the air resounded with the noise of musical instruments, such as drums, horns, and flutes. After some conversation, during which much politeness was observed in the behaviour of the king, the governor wished this ceremonial visit to be returned, &c.—The king was of the middle size, well-formed, and perfectly black, with regular features, and an open and pleasing countenance. His manner indicated understanding, and was adorned with gracefulness; and in all respects he exceeded the expectations of every person. His dress was plain; it consisted of a piece of silk wrapt loosely about him; a wreath of green silk ornamented his head; his sandals were neatly made, and curiously studded with gold. He was not distinguished by any gold ornaments, as his attendants were."*

The kingdoms along the coast are considerably different in respect of government. Among some tribes, as in Apollonia and the Slave Coast, it is absolute monarchy; in others, as in the Ahanta country, a kind of aristocracy; and in others, as among the Fantees, it consists of a variety of forms, according to some of which the power is lodged in the hands of the community at large, as in a democracy; and in others, as in Acra, it is a mixture of aristocracy and democracy. In this last mentioned country, the inhabitants of different states are known to unite occasionally for general safety, under the absolute command of individuals, as in a dictatorship; and, when the danger is past, to revert to their accustomed forms of government. The laws consequently differ considerably in the form of administration, according to the nature of the government; but, during the continuance of the slave trade, the most trifling offences was every where examined with the utmost strictness, and almost every punishment was commuted into slavery. The prevailing penalties are fines, or servitude, which are almost the same punishment, as every convict, if unable to pay his fine, becomes a slave. Even murder, though by law generally punishable with death, may be compensated by the payment of seven slaves, or their value; but if the person murdered should have been of any consequence or authority, the law of retaliation is enforced, and much bloodshed ensues. In the Fantee country the laws are more rigorous than in any other part of the coast. If any person be detected in the act of committing the most trifling theft, he forfeits his freedom; and if the article stolen should be valuable, his family becomes involved in his fate. If any one, either by accident or design, should kill a hog, a goat, even a hen, or any other animal which is the property of another, he loses his liberty, unless he can soften the injured party by presents. The law against witchcraft is peculiarly severe, and extends to all under the same roof with the offender, as they are supposed to possess some portion of the evil influence; but, since the abolition of the slave traffic, few convictions of this kind have taken place, and the rigour of the laws respecting trifling offences has begun to relax. Another oppressive law, peculiar to the Fantee country, deserves to be noticed, chiefly as demonstrating the baneful effects of the same odious trade in human beings. If a person become involved in debt, and was either unable or unwilling to pay, the creditor was at liberty to "panyar," that is, to seize and confine any person or persons belonging to the family, or the town, or even the country of the debtor; and these captives, if opportunity offered, were sold as slaves, without any delay or ceremony. During the time of the slave trade, this custom was often practised, under false pretexts of debts or offences, and many innocent persons forcibly seized, and instantly sold by private individuals, without any possibility of redress.

In the monarchical state of Apollonia, the right of succession devolves on the son of the king's sister. The reigning sovereign is the sole administrator of justice; and passes sentence without the advice of any of his subjects; but, if the accused be a person of rank, he generally receives a message, requiring him to prove his innocence by the ordeal. This consists in swallowing a portion of a certain bark, accounted poisonous, which, if rejected from the stomach, is a token of innocence, but if retained, (in which case it commonly proves fatal,) it is an evidence of guilt. In the more mixed governments, as in the Fantee country, the administration of justice and of public affairs resides principally in the pynins or elders, who are elected by the public voice, and sometimes succeed by hereditary right. They are the oracles of the laws, which they commit to memory with extraordinary correctness; and, in the trial of causes, they act at once as judges and jurors. They assemble their courts in the market-place, where both parties are attentively heard, witnesses regularly examined, and sentence duly pronounced. They have a share in all fines and forfeitures, and generally receive a present of rum when any cause of importance is brought before them. If the condemned party think himself aggrieved, he may appeal to the elders of another town or district, and sometimes to the governor of the neighbouring European fort. The natives are said to plead their causes with much ability, and to accompany their words with suitable and energetic gesture. In consequence of the strictness of the laws, crimes are extremely rare; but, during the prevalence of the slave trade, when false accusations and false witnesses abounded, condemnations occurred every day. But, though the natives rarely commit thefts against the property of their countrymen, every thing belonging to a white man is considered as a fair object of plunder. In cases of slander or evil speaking, a peculiar trial, called "brandeeing," is instituted between the parties. The injured person repairs

* Meredith's account of the Gold Coast.

to the market-place with a portion of spirits, and invites his accuser to make good his assertions, who is obliged to produce an equal quantity of liquor before he can obtain a hearing. The person found guilty is required to make a pecuniary compensation to the other; and the spirits, which in the case of wealthy individuals sometimes exceed a hundred gallons, go to the elders, and the friends of the person who is acquitted.

The religion of the natives of Guinea is not easily described. They have some notion of a Supreme Being; but their worship consists in a mass of strange and unmeaning superstitions, of which they do not attempt to give any account. They do not generally engage in any external worship; and though, on certain days, they abstain from their ordinary employments, they have no reason to assign, except that it has been the custom. In some places there is an annual sacrifice of a deer to the divinity. They seem to hold the moon in greater veneration than the sun, and welcome her appearance with great rejoicings. Their system of belief, however, is little else than a constant fear of some malignant influence, and a superstitious confidence in certain charms to avert the dreaded evil. Their object of worship, whatever it be, bears the undefinable name of Fetish, a word which some suppose to be derived from the Portuguese *fetischo*, witchcraft; but which is applied with great latitude to any thing sacred, prohibited, unlucky, or unaccountable, and is considered as equivalent to the "Obi" of the West Indies, perhaps also to the "taboo" of the South Sea islands. In Acra, the principal image, or deity, is a large mass of solid gold in the form of a human head. In the Fantee capital, Abrah, their chief object of adoration, is denominated Woorah, woorah! Agah, nannah! that is, Master, master! Father of all! But every town or village has its own favourite idol, and even in every house is some object emblematic of a divinity. The Fetish-men or women, who are considered as alone possessed of any knowledge, are not only the priests, but also the lawyers and physicians of the country. They are supposed to have communications with the demon or Fetish, and to be able to instruct their votaries in every case of actual or apprehended evil. Their good offices must be procured by presents, which are often of considerable value, and are appropriated to their own use. They are usually connected with persons in power, and are frequently useful in enforcing the authority of the laws. Where there is no monarch, and the government is lodged in the community, these persons assume great consequence, and render it hazardous for any one to withstand their influence, or to be guilty of any neglect towards the Fetish.

There are innumerable languages and dialects along the whole of the west coast of Africa; but the most prevalent in Guinea is the Fantee, which is understood from Apollonia to Acra, and to a considerable distance inland. It is soft and harmonious; but has never been reduced to writing. The following specimen gives the proper names of men and women, according to the day of the week on which they were born.

| Days of the week. | Men. | Women. |
|---|---|---|
| Sunday | Quashie | Aquishervah |
| Monday | Cudjoe | Adjuah |
| Tuesday | Quabino | Abinabah |
| Wednesday | Quacoe | Eccoah |
| Thursday | Quow | Abbah |
| Friday | Couffee | Effuah |
| Saturday | Quamina | Ambah |

The natives of the coast of Guinea are in general extremely similar in their physical qualities, and in their prevailing customs; but differ considerably in their dispositions and morals. The diversity in this respect is ascribed, with sufficient probability, to their intercourse with Europeans, and especially to the degree in which they engage in the slave trade; but seems also to arise partly from the form and character of the native governments. In most of the districts they are tall, well formed, with the usual negro features, thick lips, and flat noses. On the Grain Coast, especially in the western parts, they are mild, peaceable, honest, and industrious; but on the Ivory Coast they have become deceitful and cruel. In Apollonia, they are extremely courteous, hospitable, and brave; but generally reserved in their manners, a circumstance which has been attributed more to the despotic form of their government than their natural disposition. In the Ahantah country, they are friendly in their manners, and more free in conversation than the Apollonians, but less hospitable and courteous. The people of Chamah and Commenda are very turbulent and ferocious, addicted to frequent quarrels, and much inclined to maltreat Europeans. Those of Elmina have generally been found to be civil and peaceable; but some recent instances have occurred of their ferocity when roused by provocation. The Fantees are generally an indolent, ferocious, and faithless people; and their petty chiefs are extremely avaricious and deceitful, watching every opportunity to gratify their vicious passions. The natives of the Agonna country, especially around Winnebah, have long been noted for every species of licentiousness, living entirely by plunder, and displaying a degree of ferocity unparalleled in any other part of the coast. In Acra and Adampe, the inhabitants are remarkably indolent, addicted to drunkenness, and full of deceit; but those of Acra have been considerably improved by their intercourse with the Ashantees, a powerful people in the interior, already mentioned, and who manifest a greater attention to the rules of decency and morality than any other tribe yet discovered in the country.

"Notwithstanding some years acquaintance with the natives," (says Mr Meredith, referring principally to the Gold Coast,) "I find it no easy matter to lay down their true character; for they appear to us in a variety of forms, according to the nature of our intercourse with them, and to their employment. Those persons who are indifferent to exceed a further intimacy with Europeans, than an interchange of commodities will admit of, are to be viewed in the true light of peddling traders. When there is a prospect of a good bargain to be obtained, every species of low cunning and mercenary artifice is practised to acquire it. They accommodate themselves with much ingenuity and facility to our humours and fancies; every attitude, every expression, is carefully recommended by flexibility and supplication; yet they carefully avoid (showing) too great a desire of obtaining what would turn out profitable or advantageous to them; and, when they know that their wishes are not to be gratified as easily as was expected, disappointment is carefully concealed, and a seeming indifference is preserved in their behaviour."—"They may be justly pronounced as possessing all the chicanery inseparable from their calling, and are not readily outwitted. Those who gain a livelihood by fishing, are a laborious people; and our knowledge of them extends a little further than of the trader, because they are employed frequently by us as canoe-men and labourers. When thus employed, they perform their duty with cheerfulness; and, if encouraged, will go through a vast deal of labour; but they must be treated with exactness and punctuality. When they call for any customary allowance, or for payment, they do not like to be put off, and expect that their labour should meet with its instant reward. If they be not punctually attended to, they become neglectful, and inattentive to the interest of their employer. They are much addicted to that vice (theft), which prevails in almost every part of the world, and are very expert in the practice of it, particularly as to small articles which they can easily conceal. Men who follow an agricultural life, and who chiefly inhabit the inland parts, will be found more uniform in their conduct than the traders or fishermen. To consider them in a general view, and to make allowances for the failings attached to the uncivilized part of mankind, they may be considered a well-meaning set of men. They are divested of that low cunning and deceitful artifice, known and practised by those who gain a livelihood by a more intimate connection with Europeans. They possess no small share of honesty, sincerity, and benevolence; and are strangers to the corrupt and licentious conduct plainly to be seen among the inhabitants of the water side."—"The natives of the sea coast, from a more immediate connection with Europeans, we should suppose, are more inclined to industry than those inland; but it will be found that real industry prevails more uniformly inland, and vice is less encouraged. Every person on the coast appears very diligent in acquiring the profits of his occupation; but profligacy, drunkenness, and debauchery, are practised to a pernicious extent."

Young persons of both sexes generally go naked till the age of puberty, (which takes place in males at the age of twelve, and in females at ten,) except a girdle about the loins, with a small slip of cloth affixed to it for the sake of decency. The dress of both sexes is nearly alike, and consists in a piece of cloth, about four yards long and two broad, wrapped loosely around them; but, when engaged in any occupation, part of it is folded about the loins, and the remainder hanging down, covers the lower part of the body. The more wealthy, especially when they travel, are provided with hats, and sometimes with sandals. The women generally have their breasts uncovered; and their garment is fastened round their middle by a girdle or zone called tombah, which is supported behind by folds of cloth, forming a protuberance, in proportion to the age and rank of the wearer. Women of quality have likewise a number of silver keys suspended by a ring to the front of the girdle. The women also wear bracelets and necklaces of gold and beads, and frequently oval brass rings on their ankles. Both sexes are remarkably attentive to the decoration of their heads, and cut the hair with great nicety and taste. Some of the men allow the hair to grow on the chin, and occasionally wear whiskers and mustaches. The old men shave the whole of the head, leaving only one or two locks behind, to which they commonly keep a piece of gold suspended. The Fantees are distinguished from the other natives by small scarifications on the upper part of the cheek bones, and on the back of the neck. Both the men and women among this tribe are remarkably cleanly, and generally wash their whole bodies twice a day. The Fetish men, especially in Acra, are habited in white, a colour which is held in great veneration in all parts of the country, as emblematic of purity and perfection. The principal article of food in the Fantee country is bread, which is unleavened, and made of maize or Indian corn. In all their dishes, pepper is a necessary ingredient. Their chief mess consists of fish or poultry made into soup, with fresh palm oil, pepper, salt, and eschallots; and with this high-seasoned dish they eat bread, or yams and plantains made into a pudding. The men and women generally eat separately; and seat themselves in small parties round a bowl of soup, into which they alternately dip some bread or pudding. They do not drink during their meals; but, after finishing the repast, sometimes indulge freely in the use of palm wine or spirits. The houses are commonly made of bamboo, and plastered with a strong loamy clay, with which also the floors are laid. The towns and villages are generally surrounded by a strong fence of bamboo cane, as a protection against wild beasts.

Arts and manufactures are in a very low state among the natives. They make canoes, baskets, mats, bills, hoes, fishing nets, hooks, lines, &c. and some of them work as masons and carpenters. The women, who are literally the slaves of the men, perform most of the laborious offices, such as grinding corn, procuring food and water, every thing in short except fishing and planting. In the Ahantah country, particularly, the people are much inclined to agriculture, which is in a very rude and defective state; but in many of the maritime villages, besides acting as fishermen, they used to procure their subsistence, in a great measure, by hiring themselves as canoe men to the slave ships bound to the leeward coast. Their canoes are of various sizes, requiring fron 3 to 21 oars, or rather paddles; and some of the larger have a platform in the bottom, with an awning erected over the fore part of the deck, for the shelter of the passengers. These canoes are made of the trunks of the silk cotton tree, shaped and hollowed by a very simple iron instrument like a large chisel, answering either as axe or adze, according to the form of its handle. The wood of these trees, especially when green, is soft, and easily worked; when dry, almost as light as cork; and sometimes large enough to make a canoe paddled by twenty men, and carrying four puncheons of liquor. Those who are acquainted with the management of these canoes, conduct them through the high surf on the coast with great dexterity. On coming ashore, they watch the sea when on the point of breaking, and betake themselves to steering, by keeping the flat part of the paddle parallel to the canoe, and giving it a quick motion, moving it nearly at right angles with the canoe; and, when it is on the summit of the wave which is ready to break, this quick motion is discontinued, the paddle kept firmly in a parallel position, and the canoe, steadily balanced and directed in a straight course, flies on shore with amazing velocity.

In travelling by land, Europeans make use of a large cotton hammock, which is slung from a bamboo pole about nine feet long, and covered by a cloth in such a manner, that the person carried in it may either sit up or lie down. For a distance of 25 or 30 miles, this conveyance requires six or eight bearers, two of whom carry it by turns; and, if well supplied with rum, will travel at the rate of five miles an hour. When a party of Europeans travelling in this way arrive at a town or village, they are met by the men in their war dresses, jumping and firing their muskets heavily loaded with powder almost in the faces of the visitors; a ceremony which is not without hazard, from the occasional bursting of the pieces, and which it is necessary nevertheless to requite by a present of liquor and gunpowder.

The recreations of the younger part of the people consist chiefly in dancing and singing; and they are in most places fond of music. Their instruments consist of drums of various forms and sizes; horns made of the tusks of young elephants, and sounding like a bugle; and flutes made of a large reed, about four feet in length, open at both ends, and producing a soft and plaintive note.

Polygamy prevails in every part of the coast, and every man may have as many wives as he can maintain; but the first wife has the sole management of the domestic affairs within the house, besides acting as a watch over the fidelity of the rest. Mothers have the entire disposal of their daughters in marriage, and their consent must be procured by presents. After the payment of a certain sum, which is regulated by custom, the young woman is dressed according to her rank with rich clothes, valuable beads and ornaments of gold; and conducted by the female relatives to the house of her husband, where she is formally received by his relations and friends. On the following day she receives visits, and must continue to appear in her wedding dress for a week.

The Fantees, and most of the other tribes, bury their dead within their houses; and they are very reluctant to leave the spot where their relatives are interred. If any one die in a state of insolvency, his body does not receive the rites of burial till his debts are discharged; and the corpses of persons guilty of suicide are burned, unless a considerable sum be paid to the elders for permission to commit them to the earth. In Apollonia funerals are in general solemnized by a mixture of condoling and carousing; and every friend of the deceased contributes something expressive of regard for his memory. Cloth, spirits, and gunpowder, are lavished on these occasions; and, till the body be deposited in the ground, there is a continual succession of dances, songs, volleys of guns, and lamentable exclamations. These customary revellings, however, are performed by persons hired for the purpose, and, after the interment, the habitation of the deceased exhibits sufficient tokens of real affliction. The dead body is exposed for several days to public view, decorated with ornaments and valuable articles; and, when buried, gold, rich cloths, and other things of value, are put into the grave. At the funeral of any person of eminence, some of his slaves, generally the old and infirm, are offered in sacrifice. "In the year 1800," says Mr Meredith, "when a king of Apollonia died, one or two human beings were sacrificed every Saturday, until the grand ceremony took place, which did not happen till six months after his decease. On that occasion, upwards of fifty persons were sacrificed, and two of his youngest wives were put into the grave. The lid of the coffin was covered with human blood, and gold dust sprinkled upon it, and much gold and rich clothes were deposited in the grave.

The diseases incident to the natives of Guinea are, leprosy, which is greatly dreaded, and generally considered incurable; though, in its milder form, and when early attended to, it is sometimes removed. It is in some places supposed to be contagious, and the sufferers are excluded from society. The natives employ chiefly vesicating and excoriating substances in the milder cases. Yaws, appearing in white crusted spots on the skin, not a common but a very infectious disease, and though repressed for a time, is never radically cured. Elephantiasis, an enormous hard swelling of the legs, which is also incurable. Smallpox, which causes great ravages wherever it appears, and to which the natives in general apply no remedy; but in some parts of the coast, inoculation is practised, and the puncture usually made at the wrist. Guinea-worm, peculiar to the sea coast, and supposed to be occasioned by drinking water full of animalculæ, as it is seldom experienced in places provided with good water. It is considered by others as rather produced by absorption through the pores of the skin, as persons are known to receive it by going to the pools for water, and by infection from others. The legs are the most common seat of the disease, though occasionally it has appeared in other parts of the body. The worm itself appears no bigger than a large woollen thread of a whitish colour, and rather flattened in its form; but some have been extracted above thirteen feet in length. Much pain is felt before it protrudes through the skin, and an inflammatory tumour is produced, through which the creature makes its appearance. The natives then apply a slip of wood to the sore; and when the worm comes in contact with it, they carefully turn it round, so as to wind the worm upon it, leaving it suspended in this situation, that the weight may draw it out more speedily. If the animal is broken, the part remaining in the flesh generally recedes, and may not reappear for months; and, unless properly managed, much pain and dangerous sores are often the consequence.—Enlarged scrotum, supposed to be caused by an immoderate use of palm wine.—Dysentery, which the natives treat with great success, by administering drastic purgatives, followed by stimulating astringent clysters, making use of suppositories, keeping the patient warm, and frequently imbrocating the loins and belly with a composition of pepper.—Ophthalmia, which, though not common, is troublesome at some seasons, but chiefly occasioned by excesses in living; and is treated by the natives only with topical remedies, inserting lime juice into the eye, and drawing blood from the temples.—Fevers, which are most prevalent after the periodical rains; and excepting a few external applications, such as ablutions with warm water, and rubbing the body with certain herbs, are left by the natives to the powers of nature.—Rheumatism, a common disorder, successfully removed by tepid applications and warm clothing.—Internal inflammations, pleurisies, and pulmonary diseases, are very general during the rainy season. The medical practitioners of the country are principally females, whose skill is transmitted from one generation to another, and who perform the operations of scarification and cupping with great dexterity, as well as discover considerable botanical knowledge in the selection of herbs and plants. The male physicians are generally ranked among the Fetish men, and are much greater empyrics than the women, imposing upon the credulity, or working upon the imaginations of their patients, by pretending to expel the evil influence, or extract the supposed cause of their sufferings.

The insalubrity of the climate to Europeans is understood to have been greatly exaggerated, and to be chiefly owing to their own excesses and neglect of proper precautions. The climate of Guinea is greatly superior to that of Guiana, which lies under the same parallel; and any part of the coast, if cleared and improved, would not be less healthful, it has been affirmed, than Barbadoes, the most salubrious of the West India Islands. Strangers arriving in the country are directed, by Mr Meredith, to avoid, as much as possible, the meridian sun, by keeping within doors from eight o'clock in the morning to three in the afternoon, but to take regular exercise before and after these hours; to travel during the night with heavy clothing to protect the body from the dews, or, if necessitated to go out in the day-time, to use an umbrella, and place a handkerchief or two between the head and the hat, to rub the body well with coarse cloths, and put on warm clothing after getting wet, and, if much exposed to rain, to bathe in salt water, but never to apply spirits to the surface of the body; to use cold bathing frequently, to practice early rising, to take animal food only once a day, and to wear flannel next the body; to counteract the damp air of the wet season by heavy clothing, warm apartments, and even occasional fumigation of the rooms with vinegar, sulphur, or tobacco; and, in the dry months of December and January, to be more attentive to exercise in the open air, temperance in living, and the use of cooling laxatives. Persons just arrived in the country are particularly warned to be sparing in diet, refraining from salt meat, and freely using vegetables and acid fruits; to drink also sparingly, using chiefly rum and water, wine and water, lemonade, &c.; to take the cold bath every day, and avoid the heat of the sun as much as possible; and to keep the body gently open by means of salts, cream of tartar, or similar cooling purgatives, of which a dose should be taken every week for two months, till the constitution becomes habituated to the climate.

Europeans have hitherto made no attempt to extend their commerce to the interior of the country; but, with the exception of slaves, (which must soon cease, it is hoped, to be enumerated among articles of traffic,) have confined themselves to a very limited coast-trade. The articles of which it consists are chiefly pepper, palm oil, cowries, ivory, gold; in exchange for which, they import lead, iron, firearms, gunpowder, tobacco, spirits, tobacco pipes, vessels of brass, woollens and cottons of British manufacture, and especially East India cotton goods, which are most esteemed in the country. All the ivory is procured from the interior, and, in all the inland countries, gold is found in considerable quantities. The native traders penetrate to a great distance into the interior in quest of these articles, or rather they pass through numerous hands from nation to nation, till they reach the commercial establishments on the coast; but all the people concerned in this inland traffic are extremely mysterious in their operations, and very reluctant to communicate the slightest intelligence on the subject. It is only gold-dust that they sell to the Europeans, as they generally convert into ornaments the solid pieces, and even hold them sacred, if tolerably large. The gold of this country, whether in grains or in dust, is extremely pale, though very pure; and greatly resembles the filings of yellow copper, with which it is sometimes fraudulently mixed. This alloy is easily discovered by means of aqua fortis; but it is sometimes also imperfectly cleaned from the sand, which is of a quartzose nature, and which requires a keen eye, a glass, or even the crucible, to detect its presence. The native brokers or gold-takers are extremely skilful in this commerce, and know with the utmost precision the value of what they sell; but they are often equally well versed in the arts of knavery, requiring to be trusted with great caution, and only upon good recommendation. In Apollonia, it is said, the trader is more secure, either from exactions or impositions, and his person is considered as sacred. The gold trade is understood to have diminished considerably of late, in consequence of the more powerful princes having attempted to secure a monopoly for themselves, by compelling the weaker to renounce the working of their mines. Cowries and gold form the current medium of exchange, especially the former, as being easily reduced to the smallest sums. Forty cowries make a string; fifty strings a head, which is equal to one ackey of gold; and 16 ackeys make an ounce, which is valued at four pounds sterling.* The price of gold never fluctuates; and it is commonly estimated to yield in Europe a profit of 25 per cent. Much attention has recently been directed to the improvement and civilization of this and other tracts on the western coast of Africa; and a more interesting topic could scarcely be presented to enlightened humanity, than an enquiry into the most effectual means of promoting the benevolent object. It has been suggested, in general, to extend our trade inland, by forming alliances with the princes, and placing residents in the principal towns; thus reaching the resources of the country, securing the confidence of the natives, and enlarging the demand for European manufactures;—to encourage the progress of cultivation, by protecting planters from Europe, and directing the industry of the natives to the production of new articles of export;—to annihilate absolutely every vestige of the slave trade, to establish schools for the instruction of the people, and to exercise, in the vicinity of our settlements, as much controuling power of government as possible, for introducing salutary regulations, and enforcing orderly obedience.† "There exists no country in the world," says the French mineralogist De Montfort, "so susceptible of general cultivation. We know that certain districts of Africa are fertile in corn, and grain of every kind grows there, intermixed with sugar-canes lately introduced, and which protect the grain from hail. The plants of India, Europe, America, Australasia, or the fifth portion of the globe, will flourish there in perpetual spring, and the animals of all climates can be easily naturalized. The negroes, whose respect for the whites is extreme, notwithstanding what they have suffered from them, will cheerfully give up their lands to be cultivated by us." *Philosophical Magazine*, vol. xlvi. p. 302. See Meredith's *Account of the Gold Coast*; Smith's *Voyage to Guinea*; Peuchet's *Dict. De la Geog.*; and Playfair's *Geography*. (*q*)

GUITAR, *Guitarra* Spanish, *Chitarra* Italian, from *Cithara*, is the name of a musical instrument, commonly strung with wire; but in Spain, the guitars are always strung with catgut or bowel strings, which gives them a much finer tone. The Guitar seems to have been introduced into Spain by the Moors, and has at particular times been more or less in use in almost every part of Europe.

GULF STREAM, is the name given to a constant current in the ocean, produced by the trade winds, which are constantly blowing from east to west. This current, coming from the Pacific and Indian Oceans, passes round the Cape of Good Hope, and, after going along the coast of Africa, it crosses to America towards the equator. It is there divided, and reflected southwards to the Brazils, and running along the shores of Guiana and Terra Firma, it passes through the Caribbean Sea, and coasts along the Gulf of Mexico. Issuing from the Gulf between Cape Florida and the island of Cuba, it traverses the coasts of East Florida, the United States, New Brunswick, and Nova Scotia, and advances eastward to the banks of Newfoundland, where it turns off to the south-east, and runs through the Western Islands, from which it goes to the coast of Africa, and in a southerly direction along that coast, till it supplies the place of the waters carried away to the west by the trade winds. "It is perhaps on account of these currents," says Dr Thomas Young, "that the Red Sea is found to be about 25 feet higher than the Mediterranean.‡ Their direction may possibly have been somewhat changed in the course of many ages, and with it the level of the Mediterranean also, since the floor of the cathedral at Ravenna is now several feet lower with respect to the sea than it is supposed to have been formerly; and some steps have been found in the rock of Malta, apparently intended for ascending it, which are at present under water." M. Humboldt remarks, "that the Gulf Stream is occasioned by the current of rotation, (trade winds,) which strikes against the coasts of Veragua and Honduras, and, ascending towards the Gulf of Mexico, between Cape Caloche and Cape St Antoine, issues through the canal of Bahama. It is owing to this motion, that the vegetable productions of the Antilles are carried to Norway, Ireland, and the Canaries."

The general breadth of the Gulf Stream is about 50 or 60 miles. Sir Charles Blagden, in a voyage to America in the year 1774, found that the water of the Gulf Stream was from 6° to 11° warmer than the waters of the sea

* It is said that a labouring man, during the plentiful season from September to May, can subsist abundantly on two strings, or two-pence farthing a day; and that the usual pay of a labourer is from two to three ackies per month, *i. e.* from 10s. to 15s. currency.

† For the best views of this interesting subject, the readers may be referred to the *Reports of the African Institution*; and the accounts of these publications in the *Edinburgh Review*.

‡ The observations of the French engineers make it 6 toises or 38 feet.

through which it ran. The heat at its commencement in the Gulf of Florida was about 82°, and it lost 2° for every 3° of latitude in going northwards. It continued sensible off Nantucket.

The Gulf Stream may be easily distinguished from the other waters of the ocean, by the gulf-weed with which it is every where interspersed, and by its not sparkling in the night. In high latitudes it is always covered with a thick fog. Its breadth is diminished by north-east and east winds, which also increase the rapidity of its motion, and drive it nearer the coast. A contrary effect is produced by north-west and west winds.

The Gulf Stream passes at the distance of about 75 miles from the coast of the southern states of America. This distance, however, augments as it advances northwards. Its common velocity is about three miles an hour, and it takes about 20 days to run from Cape Florida to Newfoundland.

See Franklin's *Maritime Observations*, in the Transactions of the American Philosophical Society, vol. ii. p. 314. This paper contains a chart of the Gulf Stream, principally from the observations of Captain Folger. Blagden *On the Heat of the Water in the Gulf Stream*, in the Phil. Trans. 1781, page 334. Pownall's *Hydraulic and Nautical Observations*, 4to, London, 1787. This last work also contains a chart of the Gulf Stream. Rennel, *Phil. Trans.* 1793, vol. lxxxiii. p. 8. Humboldt's *Political Essay on the Kingdom of New Spain*, vol. i. p. 53; and Humboldt's *Voyage to the Tropics*, vol. ii. chap. 1. Young's *Natural Philosophy*, vol. i. p. 587; and Morse's *Geography*. See also Physical *Geography*.

GUMS. See Chemistry, vol. vi. p. 748, 763, 769.

Gum *Amber*. See Amber, and Chemistry, p. 766.

Gum *Ammoniac*. See Chemistry, page 769. This gum should be chosen full of drops or tears, dry, brittle, easily softened by the fire, reducible to a white powder, and of a sharp taste and smell. When thrown on live coals, the drops should burn away in a flame. In 1804, the quantity imported by the East India Company was 81 cwt. and the price per cwt. 3*l.* 11*s.* 1*d.* In 1805, the quantity was 333 cwt. and the price 1*l.* 12*s.* 2*d.* In 1806, 81 cwt. were imported at the price of 1*l.* 8*s.* 2*d.* And in 1807, 59 cwt. were imported at the price of 1*l.* 15*s.*

Gum *Anime*. See Chemistry, p. 764. This gum should be chosen in large pieces, clear and transparent. When laid on a red hot iron it melts, flames, and burns quickly away, with a fragrant smell, leaving a few light coloured ashes. Small dark coloured and opaque pieces should be rejected. The quantity imported by the East India Company from 1804 to 1808, was

| | Cwt. | Average Price per Cwt. |
|---|---|---|
| 1804 | 166 | *l* 6 8 11 |
| 1805 | 452 | 7 5 8 |
| 1806 | 268 | 4 19 2 |
| 1807 | 936 | 4 6 7 |
| 1808 | 1099 | 1 15 3 |

This gum is often sold for gum copal.

Gum *Arabic*. See Chemistry, Sect. v. p. 749. In choosing this gum, great care should be taken that it is not mixed with another kind of gum, generally in larger pieces, which, instead of dissolving completely in water, only swells in it. The following quantities were imported by the East India Company from 1804 to 1808:

| | Cwt. | Average Price per Cwt. |
|---|---|---|
| 1804 | 1767 | *l.* 4 12 1 |
| 1805 | 3931 | 4 1 11 |
| 1806 | 1534 | 2 17 8 |
| 1807 | 6565 | 2 6 10 |
| 1808 | 1382 | 2 3 3 |

Gum *Assafœtida*. See Chemistry, p. 770. The use of this gum was introduced by the Arabians about 1000 years ago. It should be chosen clear, fresh, strong-scented, and of a pale reddish colour. When broken, it should have a resemblance to marble; and by exposure to the air, it should turn of a violet red colour. That which is soft, black, and foul, is adulterated. The following quantities were imported by the East India Company from 1804 to 1808:

| | Cwt. | Average Price per Cwt. |
|---|---|---|
| 1804 | 141 | *l.* 3 15 2 |
| 1805 | 157 | 5 11 2 |
| 1806 | 82 | 3 12 8 |
| 1807 | 40 | 3 12 6 |
| 1808 | 72 | 3 17 9 |

Gum *Bdellium*, is a gum which is brought from Persia and the East Indies. It has a reddish brown colour externally, but is like glue internally. The loose drops in which it is brought home are sometimes as large as hazel nuts, but often less than a pea. They are commonly of an irregular shape. It is moderately heavy and hard, and grows tough in the mouth. It readily takes fire, burns with a bright white flame, and crackles, throwing out small fragments. It dissolves completely in vinegar.

Gum from *Botany Bay*. See Chemistry, p. 765.

Gum *Caoutchouc*. See Caoutchouc, and Chemistry, Sect. xxvi. p. 768.

Gum *Cherry tree*. See Gum *Prunus Avium*.

Gum *Copal*. See Chemistry, p. 765.

Gum *Dragon's Blood*. See Gum *Sanguis Draconis*.

Gum *Dragon*. See Gum *Tragacanth*.

Gum *Elemi*. See Chemistry, p. 764. This gum is obtained from the East Indies, as well as from Canada and Spanish America. The East India elemi is semi-transparent, of a pale yellow colour inclining to green, and is brought in cakes of 2 or 3 lbs. each, wrapped up in flag leaves. That which is soft, with a strong smell and a bitterish taste, is the best. The hard and dark coloured is never good.

Gum *Euphorbium*, is the concrete resinous juice of a prickly shrub, which grows in Malabar and various parts of India. The irregularly shaped tears of which it consists, sometimes enclose thorns, twigs, &c. The best kind is dry, clear, and of a bright light yellow colour; and is so sharp to the taste, that a small piece held a short time in the mouth will inflame it.

Gum called *Frankincense*. See Gum *Olibanum*.

Gum *Galbanum*. See Chemistry, p. 769, and Galbanum.

Gum *Gamboge*, or *Gumgutt*. See Chemistry, page 770, and Gamboge.

Gum *Guiacum*. See Chemistry, Sect. xxiv. p. 766.

Gum *Juniper*, the same as Gum *Olibanum*, which see.

Gum *Labdanum*. See Chemistry, p. 765, and Labdanum.

Gum *Lac*. See Chemistry, p. 765, and Lac.

Gum *Manna*. See Chemistry, p. 748.

Gum *Mastich.* See Chemistry, page 764, and Mastich.

Gum *Myrrh.* See Chemistry, p. 770, and Myrrh.

Gum *Olibanum*, or *Frankincense.* See Chemistry, p. 770, and Olibanum.

Gum *Opium.* See Chemistry, Sect. xviii. p. 758, and Opium.

Gum *Opponax.* See Chemistry, p. 770, and Opoponax.

Gum *Prunus Avium.* See Chemistry, p. 750.

Gum *Sagapenum.* See Sagapenum.

Gum *Sandarach.* See Chemistry, p. 764.

Gum *Sanguis Draconis.* See Chemistry, page 768. Dragon's blood in drops is preferable to that which is obtained in cakes, being more pure and compact. Genuine dragon's blood readily melts and flames, but is not soluble in water. The following quantities were imported by the East India Company:

| | Cwt. | Average Price per Cwt. |
|---|---|---|
| 1804 | 53 | *l.* 11 0 0 |
| 1805 | 103 | 3 13 0 |
| 1806 | 26 | 9 19 11 |
| 1808 | 19 | 11 6 9 |

Gum *Scammony.* See Chemistry, page 770, and Scammony.

Gum *Senegal.* See Chemistry, p. 748. This gum exudes from a prickly shrub, of the same genus with that from which gum arabic is obtained. It is chiefly used by calico printers, and in other trades where gums are employed. It dries more slowly than gum arabic.

Gum *Tacamahac.* See Chemistry, p. 764.

Gum *Thus*, or *Frankincense.* See Gum *Olibanum*, and Olibanum.

Gum *Tragacanth*, or Gum *Dragon.* See Chemistry, p. 749.

There are many other gums than those which have been mentioned, but they are not of much importance as articles of commerce. Dr Francis Buchanan informs us, that gums are collected between Seringapatam and Bangalore from the following trees:

Andersonia panshmoum. (Dr Roxburgh's MSS.)
Melia azadirachta.
Chirongia glabra. (Dr Buchanan's MSS.)
Mangifera Indica.
Cassia auriculata.
Ægle marmelos.
Shorea jala. (Dr Buchanan's MSS.)
Chloroxylon dupada. (Do.)
Bomboe gossypinum.

See Buchanan's *Journey from Madras*, &c. vol. i. p. 169. See also Milburn's *Oriental Commerce*, passim.

GUN Flints, are small pieces of flint cut into regular shapes, for the purpose of setting fire, by their collision against a piece of steel, to the priming of fowling pieces, muskets, &c.

The first stones used for this purpose were a kind of compact pyrites, or marcasite, and they were long known by that name. The species of stone used in the greater part of Europe, is called by Wallerius *silex igniarius*, and by Linnæus *silex cretaceus.* In Germany it was called *flins* or *vlins*; in the Swedish and Danish *flinta*; and in English *flint.* This name is said to be of great antiquity, as the Wends had a Pagan deity which they placed on a stone called *flynstein.* From the word flint arose the names of *flintgewehr*, *flint*, or *flinte*, which the Germans have given to guns fired by that stone. Stones seem to have been first used about the middle of the 16th century.

The manufacture of gun flints has been long kept a profound secret; and we are indebted to Dolomieu for the first exposition of the method employed in France.

The masses of flint which are best fitted for this purpose, are of a convex surface, approaching to globular. The knobbed and branched flints are commonly full of imperfections. The best flint nodules are generally between 2 and 20 pounds weight. They should be unctuous, or rather shining internally, with a grain so fine as to be imperceptible to the eye. The colour should be uniform in the same nodule, and may vary from honey yellow to a blackish brown. The fracture should be smooth and equal, and the fragments slightly conchoidal; and the transparency should be such as to allow letters to be distinguished through a thickness of one-fourth of a line when laid close to the paper. When flints do not possess these properties, either naturally, or after a long exposure to the air, they are rejected by the workmen.

Four tools are necessary in the manufacture of gun flints. 1. An iron hammer with a square head, a handle seven or eight inches long, and not exceeding two pounds in weight. This instrument is shewn in Fig. 3. Plate CCLXXXIV. 2. A hammer of well-hardened steel, with two points, a handle seven inches long, and from 10 to 16 ounces in weight. The handle must pass through in such a manner that the two points may be nearer the hand of the workman than the centre of gravity of the mass. This hammer is represented in Fig. 4. 3. A disk hammer, or roller, like a solid wheel, or the section of a cylinder, two inches and four lines in diameter, and not exceeding 12 ounces in weight. It is made of steel, not hardened, and has a handle six inches long, which passes through a square hole in the centre. It is shewn in Fig. 5. 4. A chisel, tapering and bevelled at both ends. It should be made of steel, not hardened, and six, seven, or eight inches long, and two inches wide. This chisel is represented in Fig. 6. This is set on a wooden block, which is also used as a bench for the workman. A file is necessary for restoring the edge of the chisel. With these tools the flints are formed in the following manner, which we have abridged from Dolomieu's Memoir.

1. *To break the block.* The workman seated on the ground, places the nodule of flint on his left thigh, and applies slight strokes with the square hammer, to divide it into smaller pieces of about a pound and a half each, with broad surfaces, and almost even fracture.

2. *To cleave or chip the flint.* The workman holds the piece of flint in his left hand, not supported, and strikes with the pointed hammer, No. 2. on the edges of the great planes produced by the first breaking, by which means the white coating of the flint is removed in the form of small scales, and the mass of the flint itself laid bare in the manner represented, Fig. 7. After which he continues to chip off similar scaly portions from the pure mass of the flint. These scaly portions are nearly one inch and a half wide, two inches and a half long; and their thickness in the middle is of about two lines. They are slightly convex below, and consequently leave in the part of the flint from which they were separated, a space slightly concave, longitudinally bordered by two rather projecting straight lines, or ridges, Fig. 8. These ridges, produced by the separation of the first scales, must naturally constitute nearly the middle of the subsequent piece; and such scales alone as have their ridges thus placed in the middle are fit to be made into gun flints. In this manner the workman continues to split or chip the mass of flint in various directions, until the defects usually found in the interior render it impossible to make the fracture required, or until the piece is

reduced too much to receive the small blows by which the flint is divided.

3. *To shape the gun flint.* Five different parts may be distinguished in a gun flint. 1*st.* The sloping facet, or bevel part, which is impelled against the hammer of the lock of the gun. Its width should be from two to three-twelfths of an inch; if it were broader, it would be too liable to break; and if more obtuse, the scintillation would be less brisk. 2*dly*, The sides or lateral ridges, which are always rather irregular. 3*dly*, The back, or the part opposite the tapering edge: this is the thickest part of the flint. 4*thly*, The under surface, which is uninterrupted and rather convex. And, 5*thly*, The upper facet, or small square facet between the tapering edge and the back, which receives the upper claw of the cock; it is slightly concave. In order to fashion the flint, those scales are selected that have at least one of the above-mentioned longitudinal ridges: The workman fixes on one of the two tapering borders to form the striking edge; after which, the two sides of the stone that are to form the lateral edges, as well as the part which is to form the back, are successively placed on the edge of the chisel, in such a manner, that the convex surface of the flint which rests on the fore-finger of his left hand is turned towards that tool. He then with the roulette applies some slight strokes to the flint, just opposite the edge of the chisel underneath; by which means the flint breaks exactly along the edge of the chisel.

4. *To trim the flint.* The last operation is to *trim*, or give the flint a smooth and equal edge; this is done by turning the stone, and placing the edge of its tapering end on the chisel, in which situation it is completed by five or six slight strokes with the roulette. See Plate CCLXXXIV. Fig. 9.

The whole operation of making a gun flint is performed in less than one minute. A good workman is able to manufacture a thousand good chips or scales a day, (if the flint nodules be of a good quality;) and in the same manner he can fashion 500 gun flints in a day; so that, in the space of three days, he is able to cleave and finish a thousand gun flints without farther assistance.

In this manner, five or six blows with the hammer are sufficient to produce a perfection of figure which would require more than an hour's labour, if the faces were formed by grinding them against harder substances; and less than a farthing will pay for a gun flint from the hand of the workman, though fifty times that sum would be insufficient to purchase it, if it were formed in any other way.

When the gun flints are completed, they are sorted into two classes, fine and common flints, and according to their application into flints for pistols, fowling-pieces, and muskets. A good gun flint will give 50 strokes without being unfit for service. They are sold in France at from four pence halfpenny to seven pence per hundred. They cost twice as much in Italy, and, in 1745, when they were exported from the department of the Loire and Cher to Lyons, Strasburg, and St Quintin, they cost 12 francs per thousand, or one shilling per hundred.

The manufacture of gun flints in France, employed above 800 of the inhabitants in the communes of Noyers, Couffy, and Meunes, in the department of the Loire and Cher. The mine, which is four leagues square, is thirty or forty feet deep, and thirty million of flints manufactured here were stored up in 1794. They are also made in the communes of Lye, in the department of the Indre, of Maysse and St Vincent, in the department of Ardeche, and at Cerilly in the department of the Yonne. Dolomieu received the information contained in the preceding article from Stephen Buffet, who emigrated from the commune of Meunes to the banks of the Seine, where he carried on his profession for above 30 years.

Gun flints are made also in the territory of Vicenza, and in one of the cantons of Sicily. They were manufactured in great quantities at Stevensklint in Zealand. They are also manufactured at Purfleet in Kent, and in various other parts of England, in a very superior stile.

See Dolomieu's Memoir in the *Memoires de l' Institut*. vol. iii. p. 148; in the *Journal des Mines*, No. xxxiii. p. 693; and in Nicholson's *Journal*, vol. i. 8vo. p. 88. In the *Journal des Mines*, No xxxiii. p. 713, and 719, will also be found a Memoir by M. Solivet, and observations by M. Tonellier, on the manufacture of gun flints in the commune of Cerilly. See also the *Hanoverian Magazine* for 1772; and Beckmann's *History of Inventions*, vol. iv. p. 609, &c.

GUN-Making is the art of manufacturing small arms, for the purposes of war and the chace. The name harquebuss, which was first given to small arms, is said to have been derived from the Italian word *arcobousa*, or bow with a hole, and the instrument was successively designated harquebuss, hackbut, hand-gun, match-lock, musket, snaplance, petrinal, firelock, carabine, and fowling-piece; hence the workmen acquired the appellation from the French, harquebussiers; and the British, gun-smiths and gun-makers.

The first application of gunpowder to small arms, appears to have been made by the Germans soon after the invention of cannon; for in 1471 we find that Edward the IV. brought over into England 300 Flemings, armed with hackbuts or harquebusses. The Spaniards are said to have, so early as the reign of Philip the II., adopted them in the army; and that monarch caused them to be made of a large calibre, and so heavy, that a forked rest was requisite to level them in taking aim. They were used at the siege of Rhige, and by the Emperor and Pope Leo, in 1521. The French had availed themselves of this arm, in 1667, to the extent of four harquebusses in each company of their army. England appears to have been earlier apprized of their superiority over the weapons then in use. Harquebuss soldiers formed a part of their forces in 1540; and Peter Van Collins is mentioned by Stowe as the first gun-smith, in 1543. By an act of Henry the VIII. the length of the hand, gun stock, and barrel, is directed not to exceed one yard; and that of the hackbut three quarters of a yard. By a statute of Elizabeth, they are ordered to be made all of one size and calibre, from which they acquired the name of culivers, a light kind of match-lock, fired without a rest; and their price was fixed at 13 shillings and sixpence, with flask, touch-box, laces and mould. In James the First's reign, the price was fixed at 14 shillings and ten pence. Charles the Second directs the musket barrel not to be under three feet in length, and to receive a ball of twelve in the pound; and in 1638, he grants a charter to the gun-smiths of London, by the name of master wardens and society of gun-makers; at which period they made wheel and snap-lance locks. The Scotch used the harquebuss or match-lock soon after its invention, from their intimate correspondence with France and Flanders; yet we have no certain information of their having any artists in that profession sooner than 1640, when they became incorporated with the hammermen of Edinburgh, as a pendicle of the lock-smith art. The city guard were armed with muskets or harquebusses in 1682, the expence of purchasing and maintaining of which was directed to be defrayed from the money exacted from those who entered burgess. After the union of the two kingdoms, the manufacture of small arms, (if ever carried on to any extent,) seems to have been confined to a few individuals. From the records of the hammermen, it appears that in 1715 there were only two, viz. Murdoch Grant, and John Simpson; and in 1741 there was only one in the profession. Since that period, however, greater encouragement has been given to that art in Edinburgh, there being at the present time (1816) six master gun-makers, who employ about thirty workmen; and there is one in a few of the principal towns in Scotland. This business has been carried on to a very considerable extent in England, by private individuals; and government, within these few years, has established extensive manufactories at Lewisham, and in the Tower of London, employing about 500 workmen, who complete at the rate of 5000 stand of muskets every week: Expert workmen have been paid seven guineas and upwards for their week's labour. The London gun-makers, who are employed in the making of fowling-pieces, rifles, and pistols, amount to about forty-three, and they have not less than 300 people in their service. Birmingham is the place where all kinds of fire-arms are manufactured to the greatest extent; although it is to be regretted that the effect of competition has introduced a superficial style of working, which is greatly detrimental to the character of the article, and to its extension as a branch of commercial export.

The manufacture of a gun is performed by the following workmen, viz. barrel forger, borer and filer, lock forger and filer, furniture filer, ribber and breecher, rough stocker, screwer together, polisher, and engraver, in all ten different persons, few of whom can execute any other branch of the art but one. Most of the principal towns in England have one or two master gun-makers, but none of them carry on the business in all its different branches, except London, Birmingham, and Edinburgh. The makers of the first and last cities have the highest prices for their guns, single fowling-pieces being from 15 to 30 guineas, and double ones from 35 to 70 guineas; indeed, to such a perfection has this insrument been brought, of late years, by the British artists, that it cannot be doubted but that they are greatly superior to every other nation in Europe; although we have learned that, at the Versailles manufactory, under the first consul's special patronage, fowling-pieces were made at the high price of 800 guineas. Instances, however, can be produced where London makers have had a thousand guineas for one gun. The variety and ingenuity in the construction of small arms, in order to gain peculiar advantages, are so various and extensive, that it would be very difficult to enter into any details upon the subject: We shall, however, enumerate a few of the different kinds of guns which are in use: guns with one barrel, to discharge from one to three balls successively; magazine guns that prime and load by one motion, and discharge from 10 to 20 balls in succession; double guns, with their barrels placed perpendicular, horizontal, and to turn round a centre; three, four, and seven barrelled guns; harpoon guns; muskets and carabines, &c.

*The gun barrel.*—The length, shape, and bore of gun barrels have materially changed, as the instrument became more generally used and better understood. Hence we find, in different countries and at different periods, their length fluctuating from six feet to 25 inches, and their diameters from half an inch to one and a quarter inch: They are generally cylindrical, but in some instances square, internally and externally, with chambers at the breech to contain the powder, as is the case with all the Asiatic matchlocks of most ancient construction. The Spaniards were the first people in Europe who excelled in the manufacture of barrels, remarkable for lightness and safety: Possessing finer iron from their smelting their ores with wood; and being sensible that the more it is wrought by heating and hammering, the purer it becomes, they naturally resorted to the old nails extracted from the shoes of their horses and mules. Juan Sanchez di Mirvena, is the first that forged the barrel in separate pieces, in the reign of Philip IV.; and so highly were the Madrid makers esteemed, in 1720, that the French gave 1000 livres, or 43*l.* 15*s.* sterling, for the barrels of Nicholas Biz, Juan Beler, and Juan Fernendez. About the year 1650, we find Lazerino Cominazio, of Brescia, in high repute. France has also had her eminent workmen, such as Nicol le Clerc, Des Champs, Jean Franc Renet, and Henry Renet, all of Paris, whose barrels are still much prized. The British are now, however, confessedly much superior to every other people in the manufacture of this article. They have, of late, introduced many ingenious improvements, such as patent steel barrels, and narrow and wire twist barrels, with a beautiful application of the fibres of the metal in welding, so as to resemble exactly the Damascus steel of Persia, or what is seen in the finest arms of Indian workmanship. At first the European barrels were all of one diameter throughout, until within these 30 years, that a London tradesman obtained a patent for a chambered breech, which, though it possessed peculiar merit, was nothing but a copy from the principle of the carronade, and both are obviously borrowed from the Indian matchlock; hence his privilege of original invention being untenable, this construction became general in a few years, and still continues, with some slight variation, to the present period.

In forming the common gun barrel, the workmen begin by heating and hammering out a bar of the best iron, into the form of a flat ruler, thinner at the end intended for the muzzle, and thicker at that for the breech, the length, breadth, and thickness of the whole plate being regulated by the intended length, diameter, and weight of the barrel. This oblong plate is then, by repeated heating and hammering, turned round a cylindrical rod of steel, called a mandril, whose diameter is considerably less than the intended bore of the barrel. The edges of the plate are made to overlap each other about half an inch, and are welded together by heating the tube in lengths of two or three inches at a time, and hammering it, with very brisk but moderate strokes, upon an anvil which has a number of semicircular furrows in it, adapted to barrels of different sizes. The heat required for welding is the bright white heat which immediately precedes fusion, and at which the particles of the metal unite and blend so intimately with each other, that when properly managed, not a trace is left of their former separation. Every time the barrel is withdrawn from the forge, the workmen strike the end of it once or twice gently against the anvil in an horizontal direction; this operation, which is called jumping, serves to consolidate the particles of the metal more perfectly, as well as to disengage the scoria from the inside and outside of the tube, and to obliterate any appearance of a seam. The mandril is then introduced into the bore, or cavity; and the barrel being placed in one of the furrows or moulds of the anvil, is hammered very briskly by two persons; the forger all the while turning it round in the mould, so that every point of the heated portion may come equally under the action of the hammer. These heatings and hammerings are repeated until the whole of the barrel has undergone the same operation, and is rendered as perfectly continuous as if it had been bored out of a solid piece. Twisted barrels are now generally used for the finest fowling-pieces, the method of fabricating of which is as follows. Four bars of stub iron, two feet in length, half an inch in breadth, and the first two bars half an inch thick or more, according to the size of the barrel, are previously prepared. An old barrel being welded to the extremity of one of those bars for a handle, it is heated and turned round like a cork-screw, by means of the hammer and anvil; after this, the turns of the spiral are united by heating the tube two or three inches at a time to a bright white heat, and striking the end of it several times against the anvil in a horizontal direction, with considerable force: This is called jumping the barrel, and the heats given for that purpose jumping heats: A mandril is immediately introduced into the cavity, and a quick light hammering is kept up on the welding part, until the ridges raised at the seams by the jumping are flattened, and the piece appears sound. As soon as one bar is rounded and jumped in this manner, another is welded to it, and treated in the same way, until the four pieces are united and form one tube: The old barrel is then cut off as being no longer requisite, and the operation of heating and hammering is frequently repeated in its whole length, until its external figure is correctly acquired, and the metal has arrived at the utmost closeness of fibre in all its parts. It is a circumstance of considerable importance with respect to a gun barrel, that it should be forged as nearly as possible to its weight when finished, so that very little may be taken away in the boring and filing; for as the outer surface, by having undergone the action of the hammer more immediately than any other part, is rendered more compact and pure, the less that is removed the better will the barrel be.

The next process is the boring, the apparatus for which is either driven by a water wheel, steam engine, or the hand, according to the extent of the manufacturer's demand. This operation consists in giving to the barrel its proper calibre. The boring bit is a rod of iron, somewhat longer than the barrel, one end being fitted into the socket of the crank, and the other furnished with a cylindrical plug of tempered steel, about an inch and a half long, and having its surface cut with spiral grooves, flat at bottom, and a quarter of an inch in breadth. This form gives the bit a very strong hold of the metal, and the threads, sharp at the edges, scoop out and remove every roughness and inequality from the inside of the barrel, and render the cavity smooth and equal throughout. Several bits, each a little larger than the preceding one, are afterwards successively passed through the barrel in the same way, until it has acquired the intended calibre. After this the fine boring bit is introduced, being a similar rod to the former, with a square bar of tempered steel, 10 or 12 inches long at its extremity, and finely sharpened on one of its sides; on the opposite side is placed a semicircular slip of wood, of a size sufficient to fill up with the bit the entire diameter of the barrel, two of its edges only acting on the tube, which passing through its whole length, and kept well oiled, is frequently repeated, and the bore enlarged by small slips of paper placed between the wood and the bit, until the inside presents a perfectly equal and polished surface. The trueness of the bore is then proved, either by a steel or leaden plug passed through its whole length. The next step towards completing the barrel is the operation on its exterior surface, which in common barrels is done by grinding on a large stone; two steel pins being inserted into the mouth and breech of the tube, and smaller than its diameter. The workman holding them in his hands, presses the barrel to the stone, which revolving on the pins, grinds off the inequalities left by the hammer; after which it is passed to another person who files and smooths it from one end to the other. The best barrel makers do not grind but turn their barrels on a lathe, which is well calculated to insure that perfect equality of thickness on which the strength and safety of the piece so greatly depends. The filing and smoothing is afterwards performed in the usual manner. The imperfections to which gun barrels are liable, and which render them dangerous to use, and apt to burst, are the *chink*, *crack*, and *flaw*. The first is a small rent in the direction of the length of the barrel, the second across it, and the third is a scale or plate adhering to the barrel by a narrow base, from which it spreads out like the head of a nail from its shank, and when separated leaves a pit or hollow in the metal. Chinks or flaws are of much worse consequence than the crack in fire-arms, the expansive force of the powder being exerted more upon the circumference than the length of the barrel; the flaw is much more frequent than the chink, the latter scarcely ever occurring but in plain barrels, formed out of a single plate of iron. The proof of gun-barrels, both musket and fowling pieces, as established by Government and the Gunmakers Company of London, is a ball that fits the diameter of the piece, and a charge of powder of equal weight, which being fired, either bursts the barrel, or demonstrates its soundness and safety. Some gunmakers are in the habit of following this test, by a water proof, in order to ascertain if the pores of the metal continue perfectly secure. Pistol barrels are forged in one piece, two at a time, joined by their muzzles, and are bored before they are cut asunder, by which means there is not only a saving of time and labour, but a greater certainty of the bores being the same.

Rifle barrels are of modern invention: The Germans have the merit of this contrivance. The rifle barrels of Kuchanrieter senior of Ratisbon are in the greatest esteem; and so fond are the Germans of excelling in the use of the rifle, that it has become one of their principal amusements, in which all ranks of society frequently indulge. Every town and village has their practising ground, or butts, where small prizes are competed for with an accuracy of aim that is truly surprising. The Americans have also, from their habits of hunting, acquired great correctness in the use of rifle guns; and within these few years our government has introduced them into the army; the ninety-fifth regiment being peculiarly clothed, and armed with that weapon. The manufacture of rifles, in their first formation, is exactly similar to that of other barrels, except that their external form is generally octagonal. The process of rifling is as follows: the barrel being previously bored, and finished to a true cylindrical form, is placed on the rifling machine, an instrument formed on a square plank of wood seven feet long, to which is fitted a tube about an inch in diameter, with spiral grooves deeply cut internally through its whole length, and to which is attached a circular plate, about five inches diameter, accurately divided in concentric circles, into from five to ten equal parts, and supported by two rings affixed to the plank, in which it revolves; an arm connected with the dividing plate, and pierced with holes, through which a pin is passed, regulates the change of the tube in giving the proper number of rifles to the barrel. An iron rod with a moveable handle at one end, and a steel cutter in the other, passes through the rifling tube. This rod is covered with a core of lead one foot in length, and the barrel is firmly fixed by means of two rings on the plank, standing in a straight line to the tube. The rod is then repeatedly drawn through the whole length of the barrel, until the cutter has formed one groove to the proper depth; the pin being shifted to another hole in the dividing plate, the operation of grooving is continued until the whole number that was required is complete. The barrel is then taken out of the machine and finished. This is done by casting on the end of a small iron rod a core of lead, which, when coated with fine emery and oil, is drawn for a length of time by the workman from one end of the barrel to the other, till it has acquired a high degree of smoothness and polish. The process is then complete, and the barrel is ready for the ribber and breecher, &c. The best degree of spirality is found to be half a turn in a length of three feet.

*The Lock* was originally a cleft piece of iron, moving on a pin fixed into the stock. The match was held in the cleft, and conveyed into the priming in the pan: A lever carried down the under part of the stock, and projecting at its extremity, served for a trigger. This simple contrivance was followed by the wheel-lock, so called from a small solid wheel of steel, nearly a quarter of an inch in thickness, and one and a half in diameter, cut on its edge with grooves, and notched transversely. The upper part of the circumference of this wheel rose up through the middle of the pan: It had an axis placed in its centre, to which a chain was attached, connecting itself to the extremity of a strong spring on the outside of the lock-plate, and the whole was fixed to the barrel by screws passing through the stock. Its application was by turning the wheel with a key, or spanger, which rolled the chain round its axis, and drew up the spring to its full tension. By this movement, a slider that covered the pan containing the priming, retired from over it, so as to permit the dog, which held the flint, to place itself on the edge of the wheel, which being let off by the trigger, the rapid revolutions of the wheel elicited fire from the flint, and inflamed the priming. See Fig. 8, Plate CCLXXXV. To this succeeded the *Snaplance*, in which a motion was given to the dog, or cock, and a movable plate of steel, called the frizel, or hammer, was placed vertically above the pan to receive the action of the flint. Numerous important advantages were acquired by this improvement over the wheel-lock; first, by securing the priming until the instant the piece was to be fired; and by increasing the quickness of its action and the lightness of its construction, &c. The great perfection to which this part of a gun has been carried within these 40 years in Britain, justly acquired the profession an acknowledged celebrity over every other nation. The important requisites in a gun lock are, that the action of the cock be as rapid as possible, and that it should be so placed, that on uncovering the pan, the flint may point into the centre of the priming, and as near to it as possible, without touching it. The main-spring should have a smooth and active motion; the hammer-spring should be light, and should give a slight resistance to the cock on its striking the steel, which ought to move on a roller; and the temper should not be too hard or too soft, the one extreme being known by a roughness on its surface, and the other by the flint's making scarcely any impression on it, and producing little or no fire. The inside of the lock ought to be freed and swivelled, and the tumbler and seer of steel, and also the nails, should be tempered.

A very great improvement in the construction of gun-locks has lately been made by the Rev. Mr Forsyth, minister of Belhelvie, in Aberdeenshire. This ingenious gentleman contrived and made with his own hands a lock to fire without a flint, and by percussion alone to inflame certain powders. This contrivance possesses so many advantages over the present lock, (even in its most perfect state) that it will ultimately supersede it entirely. Although it is not more than five or six years since it was made public, yet both the German and Prussian gun-makers have adopted it, and there is little doubt it will become general here, so soon as his patent expires. The great advantages of this discovery are, the rapid and complete inflammation of the *whole* charge in the chamber of the barrel, a prevention of the loss of force through the touch-hole, perfect security against rain or damp in the priming, no flash from the pan, and less risk of accidental discharge of the piece than when the common lock is used.

This lock is represented in Figs. 1, 2, 3, 4, of Plate CCLXXXV. It consists of a hammer or dog-head H, and a magazine MN. This magazine MN, a section of which is shewn in Fig. 3. consists of a roller A, round which the magazine is movable as about an axis, one end of which is screwed into the breech of the barrel, as shewn in Fig. 4. The roller is perforated through its axis by a channel *m*, Fig. 4. which communicates with the chamber S of the gun. On the upper side of the roller is a pan B, which communicates by a hole in its centre with the channel *m*, and consequently with the chamber of the piece. The priming powder, which consists of *three* parts of the hyperoxymuriate of potash, *one* part of sulphur, and *one* part of charcoal, is put into the cavity C of the magazine, which will hold 40 primings. The opposite cavity D contains the steel punch and spiral spring E. When this punch is pressed down, it strikes the pan B, and is again raised from the pan by the elasticity of the spiral spring. F, F are the screws, between the points of which, and the cork fixed on the inside of the magazine, the grease for oiling the roller is contained. In order to use this lock, the magazine is brought into the position shewn in Fig. 1, where the cavity containing the priming powder is above the pan. A small portion of the powder therefore falls into the pan. The magazine is then turned round into the position of Fig. 2. where the steel punch is uppermost at M. The hammer H being raised, and the trigger being pulled, it gives a blow to the steel punch, which strikes the priming powder in the pan, and inflames it by the concussion. The flame having no other exit, passes along the channel *m*, Fig. 4. and inflames the charge. One of the great advantages of this lock is, that it may be used during rain, and the piece will go off even if the lock is immersed in water.

A very elegant simplification of this lock has been made, by giving the magazine MN a horizontal instead of a rotatory motion. The magazine is connected with the hammer by a lever, so that when the hammer is raised, or the piece cocked, the lever pulls the magazine over the pan, and fills it with priming. When the hammer is let go, by pulling the trigger, the magazine is moved from the priming pan, and the powder is inflamed by the percussion of the extremity of the hammer. This form of the lock, however, is not water proof.

*The Stock and Mounting of Guns* has assumed a great variety of forms, and not only the figure, but the mode of holding small arms has undergone a change; the straight stock match-lock being placed under the right arm, the crooked short hagbut and the poitrinal on the breast, and the modern musket at the right shoulder. Guns of sport, till within these thirty years, were made very crooked in the stock, and no regard was then paid to the balance of the piece; since that period straight stocks have been universally adopted, and the length of the stock has been accommodated to the stature of the person for whom it is made. For a view of various constructions of small arms, see Plate CCLXXXV.

# GUNNERY,

Is the art of constructing and using great guns, for the purpose of hitting a distant object, with shot or shells, discharged from the gun by the explosive force of gunpowder.

In the present article we propose to confine ourselves to the theory of gunnery, as founded on the mathematical doctrine of projectiles, corrected and modified by experimental investigations. The art of constructing and mounting great guns, and the description of the apparatus connected with them, will form a separate article under the head of ORDNANCE.

## HISTORY.*

THE Italians seem to have been the first people that directed their attention to the subject of the motion of cannon shot. Nicholas Tartaglia, a Venetian, who was born at Brescia, published at Venice, in 1537, his *Nuova Scienza*, and in 1546 his *Quesiti e Invenzioni diverse*, in both of which he treats the subject of projectiles. In the last of these works, he gives an account of the calibre rod, or artillery measuring rod, of which he seems to have been the inventor. In another work, translated into English by Cyprian Lucas, and entitled *Colloquies concerning the Art of Shooting in Great and Small Pieces of Artillery*, Lond. 1588, he has entered more minutely into the subject. Having no knowledge of the practical part of artillery, Tartaglia investigated the subject theoretically upon fallacious principles, and can scarcely be considered as having done any great service to this branch of science. He is supposed, however, to have discovered that projectiles may be thrown to the greatest distance when they are projected at an angle of 45 degrees; and, in opposition to the notion of practical gunners, he maintained that no part of the path of a cannon ball was a straight line, but that it was like the surface of the sea, which, though to all appearance a plane, was nevertheless a portion of a circle described by the radius of the earth. Tartaglia appears also to have been the inventor of the gunner's quadrant.

The researches of Tartaglia, imperfect and unsatisfactory as they were, had the merit of directing the attention both of military engineers and mathematicians to this curious subject. Many fallacious theories of the motions of cannon shot were brought forward, and Ufano, Galeus, Ulrick, and several other writers, published tables of the comparative ranges of military projectiles, that were quite irreconcileable with experiment.

The first experimental examination of this subject was made by M. Collado, a Spaniard, who served as an engineer with the Spanish army in Italy. In his work entitled *Practica Manuale de Artiglieria*, Venice, 1586, which was first published in Italian, and afterwards in Spanish, he has given for each point of the gunner's quadrant the ranges of a falconet which carries a three pound shot. Mr Robins remarks, that it is manifest, from the number, that the falconet was not loaded with the usual quantity of powder. The following are Collado's results:

| Points of the Gunner's Quadrant. | Angle of Elevation. | Range in paces, or common steps. |
|---|---|---|
| 0 | 0° point blank | 268 |
| 1 | $7\frac{1}{2}$ | 594 |
| 2 | 15 | 794 |
| 3 | $22\frac{1}{2}$ | 954 |
| 4 | 30° | 1010 |
| 5 | $37\frac{1}{2}$ | 1040 |
| 6 | 45 | 1053 |
| 7 | $52\frac{1}{2}$ | between the 3d and 4th range. |
| 8 | 60 | between the 2d and 3d range. |
| 9 | $67\frac{1}{2}$ | between the 1st and 2d range. |
| 10 | 75 | between the 0 and 1st range. |
| 11 | $82\frac{1}{2}$ | the ball fell very near the piece. |

The next experiments which were made on this subject, appeared in the *Art of Shooting in Great Ordnance*, a work which was published in 1643 by Mr William Bourne. He assumes unity as the range for a point black shot, and ascertains the ratio of the ranges at different elevations. Bourne does not mention the nature of the piece which he used, but Mr Robins presumes that it must have been a small one. The following Table contains the results given in Chap. vii. of the above work:

| Angles of Elevation. | Ranges. |
|---|---|
| 0 | 1.000 |
| 5 | 2.222 |
| 10 | 3.366 |
| 15 | 4.366 |
| 20 | 4.833 |

36 Greatest range when a strong wind favours the motion of the projectile.
42 Greatest range in a calm day.
45 Greatest range when a strong wind opposes the motion of the projectile.

A very admirable series of experiments were made early in the 17th century, by our countrymen Eldred, who was for many years master gunner at Dover castle. His earliest experiments are dated 1611; but the book which contains them, entitled *The Gunner's Glasse*, was not published till 1646. His experiments, which are very numerous, were made with great care, and the principles on which he proceeded were simple and tolerably correct. He has published the actual ranges of different pieces of artillery, at small elevations, not exceeding ten degrees, and among these are some trials made with the famous cannon called the *basilisk*, a piece 23 feet long, and well known to those who visit Dover castle. He found that this gun, which carries a 10 lb. shot, ranged 3600 feet with 18 lb. of powder, at an inclination of 2°, and 6000 feet at an elevation of 43°.

The subject of gunnery was now destined to receive the most important improvements from the genius of Galileo. By the application of mathematics to the doctrines of motion, he has given the form of a science to this branch of natural philosophy, and has enabled us to ascertain every thing that relates to the flight of military pro-

* An account of the invention and history of ARTILLERY will be found under that article.

jectiles, on the supposition that they are discharged in a non-resisting medium. His *Discursus et Demonstrationes Mathematicæ*, &c. which contain these fine investigations, were published in 1638. They are given in the fourth dialogue, entitled *De Motu Projectorum*, and occupy fourteen propositions, in which he has proved, that a projectile must describe a parabolic curve by the combination of the force of gravity with the force of projection, and has shewn how to compute the distance to which the body will be thrown, the time of its flight, and the momentum with which it falls, when projected in a given direction, and with a given velocity. Galileo was perfectly sensible that the resistance of the air would produce a considerable change in these results, and he has described a method of discovering the magnitude of the effects which this resistance would produce on the motion of a bullet at some given distance from the gun.

The opinions which prevailed at this time respecting the extreme rarity and tenuity of the air, prevented philosophers and military engineers from availing themselves of this important part of Galileo's work. They anticipated no great variation from the theory, and accordingly we find it to have been, for a long time, the received opinion, that all projectiles moved in a parabolic curve.

This erroneous opinion was stoutly maintained by our countryman Anderson, in his treatise *Of the Genuine use and effects of the Gun*, published in 1674. This work is founded on the Galilean theory; and its author boldly undertakes to overturn all objections that can be urged against the parabolic motion of projectiles.

A similar notion is maintained by M. Blondel, in his *L'Art de jetter les bombes*, which appeared at Paris in 1683. He applies the doctrines of Galileo to the flight of shells and bullets of every kind; and after a long discussion relative to the air's resistance, he concludes that it is too minute to affect the accuracy of his deductions.

The celebrated Dr Halley held the same false opinion. He was, however, not merely misled by a belief in the extreme tenuity of the air; but he was confirmed in his errors by some very imperfect experiments. After treating of the motion of projectiles, (See *Phil. Trans.* 1685, No. 179. p. 3.) he observes, that "these rules would be rigidly true, were it not for the resistance of the medium, by which not only the direct impressed motion is continually retarded, but likewise the increase of the velocity of the fall, so that the spaces described thence are not exactly as the squares of the times; but what this resistance of the air is, against several velocities, bulks, and weights, is not so easy to determine. It is certain that the weight of air to that of water is nearly as 1 to 800; whence its weight to that of any project is given. It is very likely, that to the same velocity and magnitude, but of different matter, the resistance will be reciprocally as the weights of the shot; as also, that to shot of the same velocity and matter, but of different sizes, it should be as the diameters reciprocally; whence, generally, the resistance to shot with the same velocity, but of different diameters and materials, should be as their specific gravities into their diameters reciprocally; but whether the opposition to different velocities of the same shot be as the squares of those velocities, or as the velocities themselves, or otherwise, is yet a more difficult question. However it be, it is certain, that in large shot of metal, whose weight many thousand times surpasses that of the air, and whose force is very great in proportion to the surface, this resistance is scarcely discernible; for by several experiments made with all care and circumspection, with a mortar-piece, extraordinarily well fixed to the earth on purpose, which carried a solid brass shot of $4\frac{1}{2}$ inches diameter, and of about 14 lb. weight, the ranges above and below 45 degrees were found nearly equal; if there were any difference, the under ranges went rather the farthest; but those differences were usually less than the errors committed in ordinary practice, by the unequal goodness and dryness of the same sort of powder, by the unfitness of the shot to the bore, and by the looseness of the carriage.

In a smaller brass shot, of about $1\frac{1}{2}$ inch diameter, cast by a cross-bow, which ranged it at most about 400 feet, the force being much more equal than in the mortar-piece, this difference was found more curiously, and constantly, and most evidently the under ranges exceeded the upper. From which trials I conclude, that although, in small and light shot, the opposition of the air ought and must be accounted for, yet, in shooting of great and weighty bombs, there need be very little or no allowance made; so that these rules may be put in practice, to all intents and purposes, as if this impediment were absolutely removed."

Although the opinion which we have been considering was entertained chiefly by speculative writers, yet those who made extensive experiments on the motion of projected bodies, began to suspect some lurking error. Anderson, whom we have already mentioned, as a keen abettor of the parabolic theory, had occasion to make a number of new experiments on the ranges of shells discharged with small velocities, which he published in 1690, in his treatise entitled, *To hit a mark*. He found that the track of shells and bullets was much less incurvated in the first part of their path than they ought to be, on the Galilean theory; but instead of supposing the theory practically incorrect, or conjecturing that the deviations were produced by the resistance of the air, he imagined that the shell or bullet was discharged from the gun to a certain distance in a right line, and that gravity only began to deflect it into a parabolic curve at the end of this line, which he calls the *line of the impulse of the fire*, and which he supposes to be the same at all elevations. By giving a proper magnitude to this imaginary line, he was always able to reconcile the ranges of any two shells projected at different elevations; though, as Mr Robins remarks, he would have found it impossible to reconcile the irregularities of three or more ranges.

So deeply rooted was the erroneous notion that the air offered only an unappreciable resistance to moving balls, that the publication of Sir Isaac Newton's *Principia*, in which the resistance of the air in slow motions is ascertained and confirmed by experiment, was not able to correct it. By extending the law for slow motions to those in which the velocity was very great, it was obvious that the resistance opposed to cannon balls was too great to be overlooked; though it did not amount, by the calculation, to that enormous degree which was afterwards deduced from direct experiment. Newton has not attempted to investigate, in a direct manner, the path which a body will describe when projected into the atmosphere with a given velocity, and in a given direction. He shews, however, the particular state of density in the air, which will agree with the motion of a body in any curve whatever; and, by the application of the principle to curves, which have some resemblance to the path of a projectile, he finds it differing little from what may be considered as the path of a body projected in our atmosphere. In the second edition of the *Principia*, which appeared in 1713, he corrects some of the oversights into which he had formerly been led; and he shews that a projectile, moving in a medium, whose density varies according to certain laws, and acted upon by a force directed to the centre of the earth, will describe an eccentric spiral, whose properties he describes.

The complete solution of this problem was not obtained, till Dr Keill challenged John Bernoulli to determine the curve described by a body projected through a medium resisting as the square of the velocity. The Swiss geometer very soon gave a much more general solution than was demanded, independent of any limitation of the law of resistance, of the law of gravity, or of the law of density, provided that they were capable of being expressed algebraically. Dr Brook Taylor gave a solution of the problem in its limited form.

In the year 1690, the celebrated Huygens published a treatise on Gravity, in which he endeavoured to prove, from a series of experiments, that projectiles discharged through the air with great velocity, described paths very different from a parabola. The inconsistency of the Galilean theory, with the practice of artillery, was now particularly noticed by M. Ressons, a French artillery officer, who drew up a memoir on the subject, and presented it to the Academy of Sciences.* In this memoir, which was entitled *Methode pour tirer les bombes avec succes*, he attempts to shew that the theory is of very little service in the use of mortars, and that the theoretical path of projectiles is justly described in the works of Blondel; yet by directing mortars according to that theory, he could never obtain results that had the slightest agreement with it.

In the year 1736, a series of experiments was made at Woolwich, in order to determine the length of cannon that could enable them to shoot most efficaciously. These experiments were made with six 24 pounders, cast on purpose and of the same weight, but varying in length from 8 feet to 10½ feet. These pieces were all loaded alike, with allotments of powder equal to half the weight of the bullet; and five shot were fired from each, at an elevation of 7¼°. The following are the results which were obtained:

| Length of Pieces. | June 1st. Medium of Five ranges. | June 18th. Medium of Three Ranges. | July 2d. Medium of Three Ranges. |
|---|---|---|---|
| Feet. | Yards. | Yards. | Yards. |
| 10½ | 2486 | 2614 | 2406 |
| 10 | 2570 | 2532 | 2436 |
| 9½ | 2633 | 2560 | 2500 |
| 9 | 2790 | 2494 | 2563 |
| 8½ | 2586 | 2490 | 2466 |
| 8 | 2438 | 2473 | 2452 |

From the average range of these five shot, the effects of the different lengths were supposed to be deducible. The result of the experiments was, that the pieces of 9 and 9½ feet had the greatest range. Mr Robins has, however, shewn, that these experiments are by no means inconsistent with his opinion, that the largest pieces ought to have the greatest range. The ranges with the 9 and 9½ feet guns ought not to differ more than 35 yards from the ranges of the 8 and the 10½ feet guns, according to his theory; and yet with two subsequent trials with the 9 feet gun, the ranges differ no less than 650 yards; and the average ranges made in these successive days differ from each other 300 yards. Hence it is obvious, that these experiments differ so much from each other, that they are not sufficient to decide the point for which they were undertaken.

No step of importance seems to have been made in gunnery till the year 1742, when Dr Jurin proposed some questions, which the Royal Society appointed a committee to investigate. The first of these questions was, Whether all the powder of the charge be fired? 2*d*, Whether all the powder that is fired, be fired before the bullet is sensibly moved from its place? And, 3*dly*, Whether the distance to which the bullet is thrown may not become greater or less, by changing the form of the chamber, though the charge of powder and all other circumstances remain unchanged? The committee, after numerous experiments, found that all the powder was not fired; that the bullet was sensibly moved from its place, before all the powder that was fired had taken fire; and that a change in the form of the chamber would produce a change in the distance to which the bullet is thrown; the largest chamber of equal capacity always driving the ball farthest.† The committee, however, seem to have made some mistake; for Mr Robins afterwards proved, that the ball has not sensibly changed its place when the powder is fired.

Several experiments were about this time made in France on the ranges of cannon. M. St Remy has given us an account of a series made with pieces of cannon 10 feet in length, of the usual calibre, and elevated at an angle of 45°. The following were his results, the quantity of powder being two-thirds of the weight of the bullet.

| | Range in Yards. | | Range in Yards. |
|---|---|---|---|
| 24 Pounder . . . | 4490 | 8 Pounder . . . | 3320 |
| 16 Ditto . . . . | 4040 | 4 Ditto . . . . | 3040 |
| 12 Ditto . . . . | 3740 | | |

Pieces of the same calibre as the preceding, but somewhat shorter, had almost the same ranges when fired with only one half the former charge, or one-third of the weight of the ball in powder. See Remy's *Memoirs of Artillery*, vol. i. p. 69.

Another series of experiments was made at La Fere, in the year 1739, under the direction of the Chevalier de Borda. They were made with the usual pieces of all the preceding calibres, and were charged with various quantities of powder, and elevated to 4°, to 15°, and to 45°. Experiments were also made with a 24 pounder, at different elevations, from 4 to 45°, and the following results were obtained with a charge of nine pounds of powder.

| Angle of Elevation. | Actual Range. Yards. | Angle of Elevation. | Actual Range. Yards. |
|---|---|---|---|
| 40 . . . | . . 4100 | 20 . . . | . . . 3480 |
| 35 . . . | . . 4040 | 15 . . . | . . . 3350 |
| 30 . . . | . . 3820 | 4 . . . | . . . 1640 |
| 25 . . . | . . 3650 | | |

Another series of experiments was made at La Fere, with different pieces, elevated to different angles, and charged with different quantities of powder. The following were the results.

| Nature of the Piece. | Pounds of Powder. | Angle of Elevation. | Actual Range. Yards. |
|---|---|---|---|
| 16 | 6 | 15 | 3560 |
| 16 | 6 | 4 | 1650 |
| 12 | 4 | 15 | 3000 |
| 12 | 4 | 4 | 1640 |
| 8 | 3 | 15 | 2880 |
| 8 | 3 | 4 | 1540 |
| 4 | 2 | 15 | 3000 |
| 4 | 2 | 6 | 1724 |

In the year 1740, a series of experiments were made at Metz with great care and attention. In the experiments

* See Mem. Acad. Par. 1716, p. 79.

† See Phil. Trans. 1742, Vol. xlii. p. 172.

of La Fere, the medium ranges only were given, but at Metz the result of each trial was set down. The piece which was used was a 24 pounder, 10 feet long. It was charged with different quantities of powder, from 8 to 20 lb. It had always an elevation of 4°; but as it was placed about 78 feet above the plain where the bullets fell, the elevation should be considered as 5°. The following are the results.

| Pounds of Powder. | Ranges in Yards. | Pounds of Powder. | Ranges in Yards. |

Hitherto no general principle had been established by the numerous experiments of which we have given a short account; but the subject of gunnery was now destined to receive the most important improvements from the labours of Mr Benjamin Robins, who published an account of them in 1742, in his *New Principles of Gunnery, containing the determination of the force of Gunpowder, and the investigation of the differences in the resisting power of the air to swift and slow motions.* In this valuable work, he begins by determining the explosive force of gunpowder, (see our article GUNPOWDER, p. 187.) and he found that this force was owing to an elastic fluid like air, which existed in a highly condensed state in the powder, and being suddenly separated from it by combustion, expanded, and impelled the bullet with prodigious force.

Mr Robins then proceeds to determine the velocity with which gunpowder will impel a shot of a given weight from a cannon of given dimensions; and in order to compare the velocities thus computed with the real velocities, he invented an instrument called the Ballistic Pendulum, by which he was enabled to measure the real velocities of bullets of all kinds with such accuracy, that in the case of a bullet moving with a velocity of 1700 feet per second, the error will never amount to $\frac{1}{500}$th part of the whole.

With this machine he made a great number of experiments, with musket barrels of different lengths, charged with different quantities of powder, and carrying balls of different weights; and the agreement between the calculated and observed velocities is so surprising as to establish his theory on the firmest foundation.

Mr Robins proceeds to point out the changes which take place in the force of gunpowder, from variations in the heat and moisture of the atmosphere: He determines the velocity which the flame of gunpowder acquires by expanding itself, to be 7000 feet per second: He ascertains the manner in which the flame of the powder impels a ball, placed at a considerable distance from the charge; and he enumerates the various kinds of powder, and describes the best methods of examining its goodness.

Mr Robins then treats of the resistance of the air, and of the track described by the flight of shot and shells. He shews, from experiments made with the ballistic pendulum, that at different velocities there was a gradual increase of the resistance over the law of the square of the velocity, as the body moved quicker. He then proves, that a 24 pound ball fired with a full charge of powder, experiences, when it first issues from the piece, a resistance more than 20 times its weight; that the paths of projectiles, when the velocity of projection is considerable, is not nearly a parabola; and that, in their flight, bullets are not only depressed beneath their original direction by the action of gravity, but are frequently deflected to the right or left of that direction by the action of some other force. Robins' *Principles of Gunnery* was translated into German by Euler, who honoured it with learned and valuable commentaries.

About eight or ten years after the publication of Robins' Works, the Chevalier D'Arcy published, in the Memoirs of the Academy for 1751, a Treatise on the Theory of Artillery, in which he gives an account of a series of experiments made with great care. He employed two pendulums, against one of which he fired the ball, while the other, from which the small cannon was suspended, served to measure the recoil. These experiments were afterwards extended, and published in his *Essais d'une Theorie de l'Artillerie*, which appeared in 1760.

In the year 1746, between the 7th February and the 30th March, a series of experiments were made by the officers of artillery at Turin, for the purpose of determining the charges of powder that give the largest ranges. The guns were mounted on a part of the fortifications of the city, where the axis of the piece was 30 feet higher than the level of the country where the shot fell. The guns were fired with their axes always horizontal. The smallest charges were at first used, and increased gradually till the ranges began to diminish. The following table shews the results of the experiments:

| Nature of Guns. | Length of Bore. | Weight. | Weight of Powder. | Range. | Recoil. |
|---|---|---|---|---|---|
| | Calibres. | Cwt. qr. lb. | lb. oz. | Yards. | Inches. |
| | | | 1 4 | 478 | 43 |
| 4 | 27 | 9 1 9 | 1 10 | 489 | 62 |
| | | | 2 1 | 472 | 72 |
| | | | 2 7 | 512 | 45 |
| 8 | 27 | 18 2 10 | 3 5 | 532 | 64 |
| | | | 4 2 | 532 | 82 |
| | | | 3 5 | 505 | 42 |
| 16 | 23 | 31 3 26 | 4 6 | 526 | 55 |
| | | | 4 15 | 522 | 78 |
| | | | 6 9 | 485 | 54 |
| 32 | 20 | 57 2 17 | 8 12 | .492 | 71 |
| | | | 9 13 | 489 | 82 |

From these results it follows, that the charge of powder which gives the longest range is equal to half the weight of the shot in four and eight pounders, and to one-third of its weight in 16 and 32 pounders. The recoil always increases in proportion to the augmentation of the charge. The length of the range increases to a certain point, and afterwards decreases in a much less ratio than the recoil increases. The charge which gives the longest range in pieces of small calibre, is proportionally longer than in pieces of large calibre.

In the spring of 1750, the Chevalier Ferrero di Ponsiglione made a series of experiments with pieces of the same calibre and proportions at Turin, for the purpose of ascertaining the charge that gives the longest range when the piece is fired at the greatest elevation its carriage will admit of. The ranges were measured on a flat piece of ground, nearly on the same level with the battery. The shot being rather larger, the windage was less than in the experiments of 1746.

| Nature of Guns. | | Weight of Powder. | Length of Range. | Recoil. |
|---|---|---|---|---|
| Pounders. | Elevation. | lb. oz. | Yards. | Inches. |
| 4 | 14° | 2 1 | 2375 | 52 |
| | | 2 8 | 2219 | 60 |
| | | 2 14 | 2422 | 70 |
| | | 3 5 | 2526 | 76 |
| 8 | 11° | 3 5 | 2321 | 46 |
| | | 4 2 | 2463 | 65 |
| | | 4 15 | 2486 | 85 |
| | | 5 12 | 2375 | 102 |
| | | 6 9 | 2675 | 119 |
| 16 | 12° | 5 12 | 2659 | 71 |
| | | 6 9 | 2860 | 76 |
| | | 7 3 | 2663 | 90 |
| | | 8 3 | 2810 | 97 |
| | | 9 0 | 2764 | 108 |
| | | 9 13 | 2892 | 113 |
| 32 | 11½° | 11 8 | 3172 | 117 |
| | | 13 2 | 3032 | 120 |
| | | 14 6 | 2995 | 124 |
| | | 16 6 | 3220 | 146 |
| | | 18 0 | 3084 | 168 |

From these experiments it follows, that the charges that give the longest ranges when cannon are fired from the greatest elevations their carriages will permit, are greater than those which produce the same effect when they are fired horizontally. Several experiments which were some time afterwards made in France, shewed, that in cannon of a large calibre, the charge should be about three-eighths of the weight of a shot. In the month of August 1747, Signior Marandone made a series of experiments for the same purpose, by orders of the Knights of Malta. From these he concluded, that the charge that ought to produce the longest range, must exceed three-eighths of the weight of the shot.

Signior Mattei, mathematical instrument maker to the King of Sardinia, invented a machine for finding the initial velocity of balls measured near the mouth of the gun; and a number of valuable experiments were made with it by Antoni, of which we shall afterwards give a more particular account. Mattei's machine consists of a horizontal circle, supported by its centre on the upper end of a vertical axis, and serving as a base to a hollow paper drum. This drum is made to revolve by means of a weight at the end of a cord passing over a pulley; and the projectile, thrown in a horizontal direction, traverses the paper drum in two points. The arc described by the system, while the projectile, in traversing the interior of the drum, is measured by the distance of the second point from the diameter which passes through the first. See the Description of Plates, and p. 179.

Another very simple machine for the same purpose was invented in 1764, by Lieutenat De Butet. "He applies a little plate of metal, provided with a moveable index, to any wheel that turns with an equable motion and sufficient velocity; the index is held at some distance from the circumference of the wheel, by a thread that is stretched across the mouth of the gun. When the gun is fired, the shot breaks the thread and sets at liberty a spring, which instantly presses the index against the wheel, upon which it describes an arch, till it is checked by the impact of the shot against a moveable butt placed at the distance of a few feet; to this effect, one extremity of a rod is fastened to the butt, and the other to the plate; thus the index is drawn back by the rod which follows the movement of the butt, and ceases to describe the arch on the circumference of the wheel. The motion of the wheel, the distance from the muzzle of the gun to the butt, and the arch described by the index being known, it is easy to ascertain the space that the shot passes through in one second of time with an uniform velocity; or, in other words, its initial velocity. To diminish the friction as much as possible, a small groove is made in the part of the wheel that receives the index, and filled with grease, which presents a very slight resistance. By means of this instrument, the time of the shot's passage along the bore of the gun, the initial velocity of shells, and the resistance of the air to their motion, may be determined; if allowance be made for the modifications that must ensue."

In the year 1779, the learned Dr Hutton of Woolwich, in conjunction with several officers of artillery, undertook a series of experiments on the motion of cannon balls. They used ballistic pendulums from 300 to nearly 600 pounds weight, and they employed cannon shot of 1, 2, and 3 pounds weight, and they varied the charge of powder from 2 to 8 ounces. From these experiments, of which a full account was published in the *Philosophical Transactions* for 1778, Dr Hutton deduced the following inferences.

1. That gunpowder fires almost instantaneously. 2. That the velocities communicated to balls or shot of the same weight by different quantities of powder are nearly in the subduplicate ratio of those quantities: a small variation in defect taking place when the quantities of powder become great. 3. And when shot of different weights are employployed, with the same quantity of powder, the velocities communicated to them are nearly in the reciprocal subduplicate ratio of their weights. 4. So that, universally, shot which are of different weights, and impelled by the firing of different quantities of powder, acquire velocities which are directly as the square roots of the quantities of powder, and inversely as the square roots of the weights of the shot, nearly. 5. It would therefore be a great improvement in artillery to make use of shot of a long form, or of heavier matter; for thus the momentum of a shot, when fired with the same weight of powder, would be increased in the ratio of the square root of the weight of the shot. 6. It would also be an improvement to diminish the windage; for by so doing, one third or more of the quantity of powder might be saved. 7. When the improvements mentioned in the last two articles are considered as both taking place, it is evident that about half the quantity of powder might be saved, which is a very considerable object. But important as this saving may be, it seems to be still exceeded by that of the article of the guns; for thus a small gun may be made to have the effect and execution of another of two or three times its size in the present mode, by discharging a shot of two or three times the

weight of its natural ball or round shot: And thus a small ship might discharge shot as heavy as those of the greatest now made use of.

In the year 1781 Count Rumford instituted a series of experiments with musket barrels. The machinery which he used was ingeniously contrived and well executed, and his object was to determine the initial velocity of bullets, the recoil of the barrel, the effect of firing the charge in different parts of it, and the most advantageous situation for the vent. The following were the principal results which he obtained. He found that when the weights and dimensions of the bullets are the same, their velocities, when discharged from the same piece, are in the subduplicate ratio of the weight of the charges; and he concludes, from numerous experiments, that the vent may be placed in any part of the chamber where it will best answer on other accounts. Hence Count Rumford recommends that the bottom of the bore should be of a hemispherical form; that the vent should be brought directly through the side of the barrel in a line perpendicular to its axis, and pointing to the centre of the hemispherical concavity of the chamber.

In these experiments, the ballistic pendulum of Robins was employed; but in consequence of a suggestion contained in Robins's new principles of gunnery, Count Rumford proposed, and put in practice, another method of determining the velocities of bullets, by suspending the gun in a horizontal position by two pendulous rods, and determining the velocity of its recoil from the arc of its ascent, measured by a ribbon, as in the ballistic pendulum. The velocity of the bullet will be $v = \frac{V-U}{B} \times W$; where W is the weight of the gun, V the velocity of its recoil when fired without a bullet, V the velocity of the recoil when the same charge impels a bullet, B the weight of the bullet, and $v$ its velocity. By comparing the results obtained in this way, with others obtained from the ballistic pendulum, Count Rumford found, that in several cases they agreed, but that in others the differences were so great, that the new method ought not in general to be relied upon.

Another very extensive set of experiments was undertaken in the year 1783, under the direction of Major Bloomfield, and by the orders of the Duke of Richmond, Master-general of the Ordnance. They were carried on in the summers of 1783, 1784, 1785, 1787, 1788, 1789, 1791, &c. principally with a view to the following objects:

1. To determine the velocity of balls impelled by equal charges, from pieces of different lengths, but of the same weight and calibre.

2. To determine their velocities with different charges, when the weight and length of the gun are the same.

3. To determine the greatest velocity due to different lengths, by making the charge as great as the gun will bear.

4. To determine the effect of varying the weight of the gun, every thing else remaining the same.

5. To determine the penetration of balls into blocks of wood.

6. To determine the ranges and times of flight, and the velocities of balls, by striking the ballistic pendulum at various distances, and to compare them with their initial velocities, in order to ascertain the air's resistance.

7. To determine the effect of wads; of different degrees of ramming; of different degrees of windage, and of different positions of the vent; of chambers and trunnions, and every other circumstance necessary to be known for the improvement of artillery.

These experiments were carried on with great success, excepting in the subject of ranges, which were less regular and uniform than could have been wished. The ballistic pendulum was from 600 to 800 pounds weight. The balls were generally one pound weight, and the powder was increased from one ounce till the bore was quite full.

The following are the general results, as given by Dr. Hutton:

1. That the velocity is directly as the square root of the weight of powder, as far as to about the charge of eight ounces; and so it would continue for all charges, were the guns of an indefinite length. But as the length of the charge is increased, and bears a more considerable proportion to the length of the bore, the velocity falls the more short of that proportion.

2. That the velocity of the ball increases with the charge to a certain point, which is peculiar to each gun where it is greatest; and that, by further increasing the charge, the velocity gradually diminishes till the bore is quite full of powder. That this charge, for the greatest velocity, is greater as the gun is longer, but not greater, however, in so high a proportion as the length of the gun is; so that the part of the bore filled with powder bears a less proportion to the whole in the long guns than it does in the short ones; the part of the whole which is filled being indeed nearly in the reciprocal subduplicate ratio of the length of the empty part. And the other circumstances are as in this Table.

*Table of Charges producing the greatest Velocity.*

| Gun. | Length of the Bore. | Length filled. | Part of the whole. | Weight of the Powder. |
|---|---|---|---|---|
| Number. | Inches. | Inches. | | Ounces. |
| 1 | 28.2 | 8.2 | $\frac{3}{10}$ | 12 |
| 2 | 38.1 | 9.5 | $\frac{3}{12}$ | 14 |
| 3 | 57.4 | 10.7 | $\frac{3}{16}$ | 16 |
| 4 | 79.9 | 12.1 | $\frac{3}{20}$ | 18 |

3. It appears that the velocity continually increases as the gun is longer, though the increase in velocity is but very small in respect of the increase in length, the velocities being in a ratio somewhat less than that of the square roots of the length of the bore, but somewhat greater than that of the cube roots of the length, and is indeed nearly in the middle ratio between the two.

4. The range increases in a much less ratio than the velocity, and indeed is nearly as the square root of the velocity, the gun and elevation being the same. And when this is compared with the property of the velocity and length of gun in the foregoing paragraph, we perceive that very little is gained in the range by a great increase in the length of the gun, the charge being the same.

And, indeed, the range is nearly as the 5th root of the length of the bore, which is so small an increase as to amount only to about one-seventh part more range for a double length of gun.

5. It appears also that the time of the ball's flight is nearly as the range; the gun and the elevation being the same.

6. It appears that there is no sensible difference caused in the velocity or range, by varying the weight of the gun, nor by the use of wads, nor by different degrees of ramming, nor by firing the charge of powder in different parts of it.

7. But a great difference in the velocity arises from a small degree of windage. Indeed, with the usual established windage only, namely, about 1-20th of the calibre, no less than between 1-3d and 1-4th of the powder escapes and is lost. And as the balls are often smaller than that size, it frequently happens that half the powder is lost by unnecessary windage.

8. It appears that the resisting force of wood to balls fired into it is not constant. And that the depths penetrated by different velocities or charges are nearly as the logarithms of the charges, instead of being as the charges themselves, or, which is the same thing, as the square of the velocity,

9. These, and most other experiments, shew, that balls are greatly deflected from the direction they are projected in, and that so much as 300 or 400 yards in a range of a mile, or almost 1-4th of the range, which is nearly a deflection of an angle of 15°.

10. Finally, these experiments furnish us with the following data to a tolerable degree of accuracy, viz. the dimensions and elevation of the gun, the weight and dimensions of the powder and shot, with the range and time of flight, and the first velocity of the ball.

The experiments made by Dr Hutton in the years 1787, 1788, 1789, and 1791, were principally intended to ascertain the resistance of the air to military projectiles. Balls of 2 inches, 2.78 inches, and 3.55 inches in diameter, were employed, to determine the resistance of very high velocities. They were discharged with velocities from 300 to 2000 feet per second, and were made to strike the pendulum at several different distances from the guns. In all these experiments, the resistances varied nearly as the $2\frac{1}{10}$th power of the velocity, the exponent being 2.028 for a velocity of 200 feet per second, and increasing gradually to 2.136, which it reached when the velocity was 2000 feet per second.

In the year 1804, a new machine for measuring the initial velocity of projectiles was proposed and used by Col. Grobert; and a very favourable report of its accuracy was made to the National Institute of France, by Messrs Bossut and Monge. The apparatus consists of a horizontal revolving axis, about 34 decimetres long, having at each of its extremities a circle or disc of pasteboard placed perpendicular to the axis. A rotatory motion is communicated to the axes, and consequently to the discs, by means of a weight suspended at the extremity of a rope, which, passing over a pulley 10 or 12 yards above the ground, coils itself about the arbour of a wheel and axle fixed at the same level as the discs. The motion given to the wheel and axle by the descent of the weight is communicated to the axis of the discs by an endless chain, passing round the wheel and axle, and also round a pulley on the axis of the discs. The instrument being thus constructed, let us suppose that a ball traverses the two discs when in motion, in a direction parallel to their axes. It is obvious that the hole in each disc will not coincide with one another, and that the angular motion which the second disc has made while the ball was passing between them will be a measure from which the velocity of the ball can be computed. Hence it is necessary to impress upon the discs an uniform and known velocity, and to measure accurately the arch passed over by the second disc during the transit of the ball from the one to the other. In the experiments which were made with this machine, the motion became sensibly uniform when the weight had arived nearly at the half of the vertical space which it traversed. The following is the formula for calculating the velocity of the ball.

$$V=\frac{2\pi n}{kt}\cdot\frac{r}{a}b, \text{ or}$$

$$V=\frac{6.282n}{k\,t}\cdot\frac{r}{a}b, \text{ in which}$$

$V$=the velocity of the ball between the discs, considered as uniform;

$\pi$=3.141, the ratio of the circumference to the diameter of a circle;

$k$=the ratio between the respective numbers of the turns made at the same time by the wheel of the axle, and the pulley of the axis of the discs, which in the following experiments was $\frac{1}{7.875}$;

$t$=the time employed by the wheel of the axle to make $n$ number of turns;

$r$=the distance of the hole made by the ball in the second disc from the axis of the discs;

$a$=the arc passed over by that hole while the disc goes from the one to the other;

$b$=the distance between the two discs.

The following experiments were made with a horse musketoon, 0.765 metres of interior length. The weight of the ball was 24.7 grammes, and it was projected with half its weight of powder. The mean velocity deduced from these experiments is 390.47; whereas the mean velocity found from experiments with the common infantry musket, 1.137 metre of interior length, was 428, exceeding the former in the ratio of 11 to 10. All the values of $a$ are referred to that of $r$=1 metre.

| Number of the experiments. | Values of $n$, or the number of turns made by the wheel of the axle. | Values of $t$, or the time in which the number of turns were made. | Values of $a$, or the arc passed over by the hole in the second disc. | Values of V, or the velocity of the ball. |
|---|---|---|---|---|
| | | Seconds. | Metres. | Metres. |
| 1 | 8 | 10 | 0.3510 | 402.3 |
| 2 | 8 | 10 | 0.3800 | 371.7 |
| 3 | 8 | 10 | 0.368 | 362 5 |
| 4 | 15 | 22 | 0.296 | 384.1 |
| 5 | 15 | 22 | 0.264 | 430.7 |
| 6 | 10 | 18 | 0.268 | 345.7 |
| 7 | 15 | 16 | 0.392 | 398.8 |
| 8 | 15 | 16 | 0.392 | 398.8 |
| 9 | 15 | 16 | 0.416 | 375.8 |
| 10 | 15 | 16 | 0.360 | 434.3 |

In order to afford the means of traversing the discs by throwing balls in different directions from 0° to 45°, Colonel Grobert gives to each disc a particular horizontal axis, to which a pulley is affixed; and the rotatory motion is communicated by an endless chain to both axes, so that they may perform the same number of revolutions in the same period. The supporter of the second disc is capable of rising vertically, and fixing itself at different heights. The adjustment of this apparatus must, however, be attended with great difficulty.

## CHAP. I.

### *On the Parabolic Theory of Gunnery.**

In the process of our examination of the motions in the solar system, it appears that terrestrial gravity, or the heaviness of common sublunary bodies, is only a particular case of the mutual tendency of all matter towards all mat-

* This valuable Chapter was written by the late John Robison, LL. D. F. R. S. E. It was intended to form a part of his *System of Mechanical Philosophy*, and was the last production of that eminent philosopher. It is now published for the first time, with the permission of Mr Murray, the proprietor of the MSS. and will appear in the first volume of his *System of Mechanical Philosophy*, now in the press.

ter. It further appears, that a body on the surface of our globe gravitates in a line that is directed very nearly to the centre of the earth; and that the intensity of this gravitation is inversely proportional to the square of its distance from this centre.

Bodies let fall, or projected in any direction on the surface of this earth, move under the influence of this force; and their motions may be computed from the general doctrines of dynamics, in the same manner as we computed the motions of the planets. They will either fall in the direction of gravity, or will rise in the opposite direction, or will describe a curve line concave toward the earth, which will be an ellipsis, parabola, hyperbola, or circle, according as the velocity and direction of the projection may have been combined

But, in the greatest projections that we can make, the force of gravity is so nearly the same in every point of the path, that we may suppose it to be accurately so, without any sensible error, were it ten times greater than it is. Therefore in all disquisitions about projectiles, it would be useless affectation to embarrass ourselves with the variations. None of our projectiles rise a mile in the air, which is about $\frac{1}{3960}$ of the mean radius of the earth, and will occasion a diminution of gravity nearly equal to $\frac{1}{1980}$, a quantity altogether insignificant.

For the same reasons, although the directions of gravity in the different points of the projectile's flight, are lines converging nearly to the centre of the earth, we may consider them as all parallel, because none of our projectiles fly four miles, which produces a convergency of nearly four minutes, a deviation from parallelism which needs not be regarded.

In general, therefore, we may consider all such projectiles as under the influence of equal gravity, acting in lines parallel to the vertical or plum-line drawn through the place of projection. This reduces the theory of projectiles to a great degree of simplicity.

Accordingly, this is the first department of mechanical philosophy which first received improvement by the application of mathematical knowledge. We are indebted for this fortunate introduction of mathematics into the doctrines of motion, to the celebrated Florentine, Galileo Galilei. This excellent philosopher read his discourses on local motion about the beginning of the 17th century. Those lectures contain the whole of this doctrine, nearly in the state in which it continued till about the middle of last century. There is no branch of natural philosophy that has met with so much assistance and encouragement, it having been considered in all nations as the foundation of the art of gunnery; an art unfortunately too much connected with the security of every nation. It has therefore been patronised by princes and magistrates—most costly establishments have been made for its cultivation; the mathematicians have occupied themselves with its problems, and more numerous and expensive volumes have been published on this than on any other part of mechanical philosophy. Yet there is none in which so little improvement has been made. Galileo's lessons contain every thing that has been done in a scientific way, till M. Robins, in 1742, gave it a form altogether new.

We shall first consider the perpendicular ascents and descents of heavy bodies; and in the next place, their curvilineal motion, when projected in directions deviating from the vertical.

The motion of a falling body is uniformly accelerated, and that of a body thrown straight upward is uniformly retarded.

For the accelerating or retarding force is constant, and therefore the motions are such as were considered in Dynamics.

All the characteristic phenomena of these motions having already been sufficiently considered, all that is wanting for the application to this class of mechanical phenomena, is merely one experimental determination of the accelerative power of gravity, that is, the velocity, or increment of velocity, which gravity will generate in a body by acting on it uniformly during some given time. Galileo, who first demonstrated that an invariable gravity must produce a uniformly accelerated motion, was also among the first who appealed to experiment in all inquiries. We now think lightly of this, and wonder that a man shall think of another argument who has this in his power. But when Galileo began to communicate his knowledge to the world, this was the last support that a philosopher would think of. They had received a parcel of topics from their master, which had been handed down in the schools during many ages; and from these was every thing accounted for or explained. Aristotle, or his immediate pupils, had said that the velocities of falling bodies increased with their weights; Galileo's doctrine was incompatible with this, and he thought himself obliged to use arguments in his support. He said, that if Aristotle's doctrine be true, two crown pieces must fall faster when sticking together than when unconnected, which, said he, is contrary to common experience. Not doubting that he had convinced his audience, he described the experiments which he was to exhibit next day, shewing that in a double time a body would fall four times as far, &c. The experiments were performed in the dome of the great church, before a vast concourse of people, and succeeded most perfectly. Yet so little were the philosophers moved by this kind of argument, that they represented Galileo as a dangerous person, unfriendly to the state; and he was obliged to leave his native city in a few days, and take shelter in Padua. It is very remarkable that Baliani, one of the first geometers and mathematicians of that age, and who perfectly understood Galileo's speculations on this subject, should teach another doctrine, reviving or supporting an old scholastic assertion, that the velocity of a falling body might be as the space fallen through, calling this motion also a uniformly accelerated motion.

Galileo found more difficulty than one should expect in his endeavours to obtain an exact measure of the power of gravity; and indeed could not obtain one that was satisfactory. But the difficulty of the task, and his struggle to accomplish it, were big with advantages to science. A body falls so fast, that a considerable error in the conclusion arises from a very small error in estimating the time; and the great difficulty was how to estimate the time. It was in this casting about for a measure of a small portion of time that Galileo first thought of the pendulum. His penetrating and sagacious mind enabled him to see that there must be a fixed proportion between the time of a vibration and that of falling through its length, although his mathematical knowledge did not yet enable him to find it out; he saw an immediate consequence of this, if true, namely, that the vibrations of two pendulums should be in the subduplicate ratio of the lengths, because this must be the proportions of the times of falling through those lengths. This he would try; and he found that it was so. Delighted with this success, he immediately compared the time of falling from the top of the great dome with that of a pendulous vibration, by making a pendulum of such a length that it performed precisely one vibration in the time of the fall. In this time the body, moving with the final velocity, would describe a space double of that fallen through. He then counted with patience the number of vibrations made by his pendulum in an interval of time, measured by the transit of two stars. Thus he obtained the time, and the velocity generated in that time, by the uniform action of gravity. Galileo made this to be about 31 feet of our measure in a second, and said that it was certainly somewhat more; because his experiments on falling bodies convinced him that their motion is retarded by the air.

These efforts and resources of an ingenious mind are worthy of record, and are instructive to others. But Galileo did not attain the accuracy in this measure that we now possess. The honour of the accurate statement of the time of a pendulous oscillation, and that of the fall through its length, was reserved for Mr Huygens. This proportion was determined by him by a most ingenious and elegant physico-mathematical process. He also gave us the pendulum clock, by which time can be measured with as much accuracy as a line can be divided.

Aided by these inventions, we have now obtained the most precise measure of the accelerating powers of gravity; and we can now say that its intensity is such in the latitude of London, that by acting uniformly on a body for one second of time, it generates in it the velocity of 32 feet two inches per second, and a heavy body falls 16 feet one inch in that time.

These are standard numbers, of continual use in all mechanical discussions, and should be carefully kept in remembrance. Not only so, but we should acquire distinct notions of them in this respect, viz. as standard numbers. Gravity is known to us in two ways; our most familiar acquaintance with it is as a pressure, which we feel when we carry a heavy body. With this we can compare the pressure of a spring, the exertion of an animal, the pressure of a stream of water or wind, the intensity of an attraction, &c. by setting them in opposition and equilibrium. The philosopher, and especially the physical astronomer, and cultivator of the Newtonian philosophy, is well acquainted with gravity as an accelerating and a moving force, capable of accelerating, retarding, or deflecting the body in which it inheres, or on whose intimate particles it acts without intermedium. He can compare the gravity of a stone with that of the moon, or of Jupiter, or with the force that produces the precession of the equinoxes. The general mechanician, observing that all other pressures, such as that of a spring, of an animal, &c. are also moving forces, by combining those two aspects of gravity, makes a most important use of it, by comparing other forces with weights, and thence inferring the motions which those forces will produce. Thus, knowing that an arrow $\frac{7}{8}$ oz. weight, by falling 18 inches, acquires the velocity of $10\frac{1}{2}$ feet per second, he infers, that when drawn to the head by a bow of 62 pounds, it will be discharged with the velocity of 233 feet per second.

We shall therefore, in future, compare every force with gravity, and express the accelerating power of this standard by 32, meaning, that by acting on every particle of a body for a second, it will generate the velocity of 32 feet per second, and cause the body to describe 16 feet with a motion uniformly accelerated. We may find it convenient, on some occasions, to use the numbers 386, and 193, which are the inches in $32\frac{2}{12}$ and $16\frac{1}{12}$ feet.

The questions that interest us at present are, those concerning the relations between the time $t$ of any fall, the height $h$ of that fall, and the velocity $v$ that is uniformly acquired in falling; so that when any one of those things is given, the others may be found out.

I. Since the variations of velocity are proportional to the times in which they are produced, we have

$$1'' : t'' = 32 : 32t''$$
$$\text{and } v' = 32t''$$
$$\text{and } t'' = \frac{v'}{32}.$$

N. B. The time $t$ is always supposed to be a number of seconds, and the height $h$ a number of feet, and the velocity $v$ a number of feet uniformly moved over in one second.

A falling body, therefore, acquires an increment of 32 feet per second in every second of its fall, and an ascending body has its velocity lessened as much during every second of its rise. A body *falling* during four seconds, acquires the velocity of 128 feet per second.

But if the body has been projected downward with the velocity of 100 feet per second, then at the end of 4″, it is moving at the rate of 228 feet per second.

A body projected straight upwards with the velocity of 160 feet per second, will at the end of the first second of its rise, have the velocity 128. At the end of 2″ it will be moving at the rate of 96 feet per second. Its velocity at the end of the third second will be 64. At the end of the fourth second, it will be 32, and at the end of five seconds it will stop, and begin to fall.

The times of the rise and the subsequent fall are equal.

II. Since the heights are as the squares of the times of the fall or ascent, we have

$$1'' : t^2 = 16 : 16\,t^2$$
$$\text{and } h = 16\,t^2 \text{ and } \sqrt{h} = 4\,t.$$
$$\text{also } t^2 = \frac{h}{16}, \text{ and } t = \frac{\sqrt{h}}{4}.$$

A heavy body, falling during four seconds, falls 256 feet.

A body rising straight upwards 144 feet employs 3 seconds in its ascent.

III. Because the heights fallen through are also proportional to the squares of the velocities acquired at the end of the fall, we have

$$32^2 : v^2 = 16 : h$$
$$\text{and } h = \frac{16}{32^2}\,v^2, \text{ and } \sqrt{h} = \frac{4}{32}\,v, = \frac{v}{8}$$
$$\text{and, conversely, } v = 8\sqrt{h}, \text{ and } v^2 = 64\,h.$$

All questions concerning the perpendicular ascents and descents of heavy bodies may be solved by means of the two equations

$$v = 32\,t = g\,t$$
$$h = 16\,t^2 = \tfrac{1}{2}g\,t^2.$$

An easy mode of extempore computations is had, by remarking, that since a heavy body falls 16 feet in a second, and acquires the velocity 32, it falls 1 foot in $\frac{1}{4}$th of a second, and acquires the velocity 8.

In every second of the fall, the velocity is increased by 32; and in every foot of the fall, the square of the velocity is increased by 64.

In many questions, particularly in hydraulics, it is convenient to have the measures in inches.

Now, $\sqrt{193} : \sqrt{1} = 386 : 27{,}785$. Therefore a heavy body by falling one inch acquires the velocity 27,785 inches, or nearly $27\frac{3}{4}$ inches per second.

Did gravity impel a body uniformly along a space equal to the radius of the earth, it would generate the velocity which would enable the body to describe a parabola, having the centre of the earth for its focus. If projected straight upwards with this velocity it would never return.

Now $\sqrt{16} : \sqrt{\text{Earth's rad.}} = 32 : 36{,}680$ feet. This is the velocity now spoken of. Suppose the earth uniformly dense, and a pit to the centre. A heavy body would acquire, by falling down this pit, the velocity 25,866. Greater velocities than either of these can be produced by forces which we know. *Aurum fulminans* expands with the velocity of at least 42 miles per second.

It does not seem necessary to insist further on the rectilineal ascents and descents of heavy bodies, and therefore we proceed to consider their curvilineal motions, when projected in any direction that deviates from the perpendicular. These are the motions which are understood to form what is called PROJECTILES.

These motions are not only interesting to the philosophical mechanist, as examples of a constant deflecting force, and a uniform deflection in parallel lines, but also to the artillerist; because the motion of shot and shells are cases of this question, which comprehend the whole of his art. It has therefore been very much cultivated; and there is no branch of mechanical philosophy on which so much has been written, or so many experiments made for its improvement. The experimental cultivation of this branch could scarcely be prosecuted by private persons; but, in all the states of Europe, there are public establishments for this purpose, and no expence has been spared for bringing to perfection an art on which the fate of nations has unfortunately much dependence.

But, notwithstanding this liberal encouragement, and the numberless volumes which have been published on the subject, it cannot be said to have improved much as a science since it came out of the hands of its inventor, and his immediate pupil Tartaglia; and we shall be greatly disappointed if we look for that nice agreement between the results of the most approved theory and what we observe in the flight of great shot and shells. The theory, however, is unexceptionable; and the enormous deviations that we see in the actual performance of artillery, is owing to the resistance of the air. This was long considered as insignificant, even after Newton had given us sufficient information to the contrary. But the gentlemen of the profession made little account of the speculations of a private philosopher, and continued to regulate their theories by notions of their own. They have been at last convinced of their mistake by the curious experiments and discoveries of Mr Robins, and are improving their practice in some measure. But we now find, that the theory of the motion of heavy bodies through a resisting fluid, is one of the most abstruse and difficult tasks that the mechanician can take in hand.

At present, we are about to consider this subject merely as a particular case of motions regulated by gravitation, reserving the particular consideration of the modifications of these motions by the resistance of the air, till we shall have made ourselves acquainted with the general laws of such resistance.

Let a body (Plate CCLXXXVI. Fig. 1.) be projected in any direction AB, which deviates from the vertical AW. Then it would move on in this direction, and in equal succeeding moments would describe the equal spaces AB, BH, HI, IK, KL, &c. But suppose, that when the body is at B it receives an instantaneous impulse in the direction of the vertical BB′, such that by this impulse it would describe the line B *b* uniformly in the same time that it would have continued its motion along BH. Or, to speak more accurately, let the motion or velocity B *b* be compounded with the motion BH. The body must describe the diagonal BC of a parallelogram B *b* CH, and, at the end of this second moment, it must be in C, in the vertical line HCC′, and moving with the velocity BC. Therefore, in the third moment it would describe CN, equal to BC. But let another impulse in the direction of the vertical CC′ generate the velocity C *c*, equal to B *b*. By the composition of this with the motion CN, the body will describe the diagonal CD of the parallelogram C *c* DN, and at the end of the third moment must be in D, moving in the direction and with the velocity CD. It would describe DO equal to CD in the fourth moment. Another impulse of gravity D *d*, in the vertical, and equal to either of the former impulses, will make the body describe DE; and an equal impulse E *e* will deflect the body into EF; and another impulse F *f* will deflect it into FG, &c.

Thus it is plain that the body, by the composition of these equal and parallel impulses, will describe the polygonal figure ABCDEFG, all in one vertical plane, and in every instant or point, such as E, will be found in the vertical line KE, drawn from the point at which it would have arrived in that instant by the primitive projection.

Now, let the interval between these impulses be diminished, and their number be increased without end. It is evident that this polygonal motion will ultimately coincide with the motion in a path of continued curvation, by the continual and unvaried action of gravity.

The line described by the body has evidently the following properties.

*1st*, If a number of equidistant vertical lines BB′, HCC′, IDD′, KEE′, &c. be drawn, cutting the curve in B, C, D, E, &c. and if the chords AB, BC, CD, DE, &c. drawn through the points of intersection, be produced till they cut the verticals in H, N, O, P, &c. the intercepted portions HC, ND, OE, PF, &c. are all equal.

*2d*, The curve is a parabola, in which the verticals BB′, CC′, &c. are diameters. The property mentioned in the last paragraph belongs exclusively to the parabola. As the circle is the curve of uniform deflection in the direction of the radius, so the parabola is the curve of uniform deflection in the direction of the diameter. That the curve in which the chords drawn through the intersection of equidistant verticals cut off equal portions of these verticals is a parabola, is easily proved in a variety of ways. Since B *b*, C *c*, D *d*, E *e*, are all equal, and the verticals are equidistant, B *c d* E must be a straight line. So must C *d e* F; BE must be parallel to CD, and CF to DE. Therefore BF and CE are parallel, and are bisected in *m* and *o* by the vertical DD′. Also, if FC be produced till it meet the next vertical in *i*, *i* B is equal to D *m*. All this is very plain. Hence

$$i\,B, \text{ or } D\,m : d\,m = BF : m\,F, = m\,F, : o\,E;$$
$$\text{but} \quad d\,m : D\,o = m\,F : o\,E;$$
$$\text{therefore } D\,m : D\,o = m\,F^2 : o\,E^2;$$

and D, E, F are in a parabola, of which D *m* is a diameter, and *o* E, *m* F are semiordinates. We should prove, in the same manner, that BG is parallel to CF, and AG to BF, and $D\,m : DD' = m\,F^2 : D'G^2$, and the points D, F, G, in the same parabola.

Thus we have demonstrated, that the equal and parallel impulse of gravity produces a motion in a parabola, whose diameters are perpendicular to the horizon. This was the great discovery of Galileo, and the finest example of his genius. His discoveries in the heavens have indeed attracted more notice, and he is oftener spoken of as the first person who shewed the mountains in the moon, the phases of Venus, the satellites of Jupiter, &c. But in all these he was obliged to his telescope; and another person who had common curiosity would have seen the same things. But, in the present discovery, every step was an effort of judgment and reasoning, and the whole investigation was altogether novel. No attempt had been made, since the first dawn of mechanical science, to explain a curvilineal motion of any kind; and even the law of the composition of motion, though faintly seen by the ancients, had never been applied to any use (except by Stevinus) till this sagacious philosopher saw its immense importance, and brought it into constant service.

The process employed by Galileo in this investigation, and which has been copied by almost all the writers on the subject, is considerably different from the one now gone through. Galileo supposes the heavy body to fall in the vertical BB′ with a uniformly accelerated motion, describing spaces as the squares of the times. He supposes this motion to be compounded with the uniform motion in the direction of the tangent BR. Then, supposing that B $t$ and BT are fallen through while B $r$ and BR are described by the motion of projection, it follows, that because B $r$ is to BR as the time of describing B $r$ to the time of describing BR, we shall have B $t$ : BT $=$ B $r^2$ : BR$^2$. Therefore, completing the parallelograms B $t$ C $r$, BTSR, we have B $t$ : BT $= t$ C : TS, and the points B, C, S are in a parabola, whose diameter is BT, and has BR a tangent in B.

No doubt, the result of these suppositions agrees perfectly with the phenomena, and gives a very easy and elegant solution of the question. But, in the first place, it is more difficult, or takes more discourse, to prove this continued composition of motion (almost peculiar to the case) than to demonstrate the parabolic figure: and, secondly, it is not a just narration of the fact of the procedure of nature. There is no composition of such motions as are here supposed. When the body is at C, there is not a motion in the direction parallel to B $r$, compounding itself with a motion in the vertical, having the velocity which the falling body would have as it passes through the point $t$. The body is really moving in the direction CS of the tangent to the parabola, and it there receives the same infinitesimal impulse of gravity that it received at B. Its deflection, therefore, from the line of its motion, does not make any finite angle with that motion. Therefore, although Galileo's demonstration does very well for a mere mathematical process, like the navigator's calculation of the ship's place by tables of difference of latitude and departure, it by no means answers the purpose of the philosophical investigation of a natural phenomenon. The method we have followed is a bare narration of the facts; considering the motion of the body in every instant as it really is, and stating the force then really affecting its motion.

We have not scrupled to make use of the method employed by Newton in the demonstration of his fundamental proposition on curvilineal motions, first conceiving the action of gravity to be subsultory, and the motion to be polygonal, and then inferring a similar result from the uninterrupted action of gravity. But if any person is so fastidious as to object to this, (as John Bernoulli has done to Newton's method,) he may remark, that the motion B $b$, which we compared with BH, in order to produce the motion BC, is just double of the space B $t$, through which the body falls during the motion along BH. Therefore the figure will be such, that the curvilineal deflection will be one half of B $b$, or of HC, and the tangent to the curve, whatever it is, will bisect HC. Then, during the next moment, since the deflective action of gravity is supposed the same, the body will be as much deflected from its path in C, that is, from the new tangent CS, whatever direction that tangent may have, as it was in the preceding moment. This gives us $s$ D equal to $r$ C, and this obtains throughout. Without entering on any discussion on the progress of the deflection in the different points of the arch BC or CD, it is enough for our purpose to shew that the curve described is such, that when equidistant verticals are drawn, and tangents drawn through their intersections with the curve, the portions of the verticals cut off by the tangents are everywhere equal. This also is a property of the parabola exclusively. That BCD is a parabola, of which BT is a diameter, and BR a tangent, is easily seen. For, drawing D $u$ parallel to BR, it is plain that $v$ N $=2\,r$ C, and ND $=2\,s$ D, $=2\,r$ C. Therefore $v$ D $=4\,r$ C, and B $u=4$ B $t$, and B $t$ : B $u = t$ C$^2$ : $u$ D$^2$. And we should prove, in the same manner, that $y$ E $=9\,r$ C, &c.

Having thus ascertained the general nature of the path of a projectile, we must now examine its motion in this path, determining its velocity in the different points, and the time employed in the description of the arches. For this purpose we must first ascertain the precise parabola described under the conditions of the projection, that is, depending on its direction and velocity. To do this in a way naturally connected with the acting forces, we shall consider the velocity of projection as having been generated by falling through some determinate height.

Let us therefore suppose that the body is projected from B, Plate CCLXXXVI. Fig. 1. in the direction BR, with the velocity acquired by falling through the vertical VB. Make BT equal to VB, and BR equal to VT or 2 VB, and, lastly, draw TS parallel to BR, meeting the parabola in S.

It is plain that BR is the space which would be uniformly described with the velocity of projection in the time of falling through VB. Also B $r$ is the space that would be uniformly described, with the same velocity, in the time of falling through B $t$. Therefore BR is to B $r$ as the time of falling through VB to that of falling through B $t$. But, since BT is equal to VB, B $r$ is to BR as the time of falling through B $t$ to the time of falling through BT. Therefore BR is to B$r$ as the time of falling through VB to that of falling through B$t$. But, since BT is equal to VB, B $r$ is to BR as the time of falling through B $t$ to the time of falling through BT. Therefore we have B $t$ : BT $=$ B$r^2$ : BR$^2$. But, in the parabola, we have B $t$ : BT $= t$ C$^2$ : TS$^2$, $=$ B$^2$ : TS$^2$. Therefore TS is equal to BR, or to twice VB or BT. Therefore TS$^2$ $=4$ BT$^2$, $=4$ BT $\times$ BV, $=$ BT $\times$ 4 BV. But, in a parabola, the square of any ordinate TS is equal to the rectangle of the absciss BT and the parameter of that diameter. Therefore 4 VB is the parameter of the diameter BT, and VB is the fourth part of that parameter.

If, therefore the horizontal line VZ be drawn, it is the directrix of the parabola described by a body projected from B in any direction, with the velocity acquired by falling from V.

*Cor.* 1. As this is true for any other point, C, D, &c. it follows that the velocity in any point of the path is that which a heavy body would acquire by falling from the directrix to that point.

*Cor.* 2. Hence also we learn that the velocities in any two points, such as B and D, are proportional to the portions $v\,y$ and D $t$ of the tangents through those points which are intercepted by the same diameters. Thus, $vy$ is a portion of the tangent B $y$, intercepted by the diameters DD′ and EE′, which also intercept a portion of the tangent D $t$. For these portions of tangents are in the subduplicate ratio of the lines VB and ZD. Now the velocities acquired by falling through VB and ZD are in this subduplicate ratio of the spaces fallen through.

Such is the Galilean Theory of the parabolic motion of projectiles; a doctrine valuable for its intrinsic excellence, and which will always be respectable among philosophers, as the first example of a problem in the higher department of mechanical philosophy.

We are now to consider it as the foundation of the art of gunnery. But it may be affirmed, at setting out, that the theory is of very little use for directing the practice of cannonading. Here it is necessary to approach as near as possible to the object, and the hurry of service allows no time for geometrical methods of pointing the piece after each discharge. When the gun is within 300 yards of the object, the gunner points it straight on it, or rather a little above, to compensate for the small deflection which obtains, even at this small distance. Sometimes the piece is elevated at a small angle, and the shot, discharged with a very moderate velocity, drops on the ground, and bounds along, destroying the enemy's troops. But, in all these cases, the gunner is directed entirely by practice, and it cannot be said that the parabolic theory is of any service to him.

Its principal use is for directing the bombardier in the throwing of shells. With these it is proposed to destroy buildings, to break through the roofs of magazines, to destroy troops by bursting among them, &c. Such objects being generally under cover of the works of a place, cannot be hit by a direct shot, and therefore the shells are thrown with such elevated directions, that they get over the works, and produce their effect. These shells are of great weight, sometimes exceeding 200 lb. The mortar from which they are discharged must be exceedingly strong, that it may resist the explosion of the powder able to impel this vast mass to a great distance. They are therefore most unwieldy; and it is found most convenient to have them almost solid, and unchangeable in their position. The shell is thrown to the intended distance by employing a proper quantity of powder. This is found incomparably easier than to vary the elevation of the mortar. We shall also find, that when a proper elevation has been selected, a small deviation from it, unavoidable in such service, is much less detrimental than if another elevation had been chosen. Mortars, therefore, are frequently cast in one piece with their bed or carriage, having an elevation that is not far from being the best on all ordinary occasions, and the rest is done by repeated trials with different charges of powder.

Still, however, in this practice, the parabolic motion must be understood, that the bombardier may avail himself of any occasional circumstance that may be of advantage to him. We shall therefore consider the chief problems that the artillerist has to resolve, but with the utmost brevity; and the reader will soon see, that more minute discussion would be of very little service.

The velocity of projection is measured by the fall that is necessary for acquiring it. It has generally been called the force, or IMPETUS; we shall distinguish it by the symbol $f$. Thus, in Plate CCLXXXVI. and Fig. 2, 3, 4, FA is the height through which the body is supposed to fall, in order to acquire the velocity with which it is projected from A.

The distance AB between the piece of ordnance and the object, is called the AMPLITUDE, and also the range $=r$.

Let the angle EAB contained between the vertical and the direction of the object be called the ANGLE OF POSITION $=p$.

And let the angle DAB, contained between that direction and the axis of the piece, be called the direction of the mortar $=d$, and let $z$ express the zenith distance or angle EAD, contained between the axis of the mortar and the vertical line AE.

The leading problem from which almost all the others may be derived, is the following.

Let a shell be thrown from A, (Fig. 3, 4.) with the velocity required by falling through the vertical FA, so as to hit an object B. Required the direction AD of the projection.

Let AH be a horizontal line, and AB the line of position of the object. In the vertical AF, take AE $=$ 4 AF, and on EA describe an arch of a circle ED $d$ A, which shall touch the line of position AB. Draw through the object the vertical line BD, cutting the circle in D and $d$, and join AD and A $d$. I say that AD or A $d$ are the directions required. Join ED and E $d$.

For, because AB touches the circle in A, the angle ADE is equal to the exterior angle EA $a$, or DBA, and the alternate angles EAD, ADB are equal. The triangles ADB and EAD are therefore similar, and DB : DA $=$ DA : AE, and $DA^2 = DB \times EA$. Therefore B is in a parabola, of which the vertical AI is a diameter, AD a tangent in A, and AE the parameter of that diameter. If, therefore, the body be projected from A in the direction AD, with the velocity acquired by falling through FA, the fourth part of this parameter, it will describe a parabola AVB which passes through B.

By the same reasoning, it is demonstrated that the body will hit the mark B, if projected in the direction A $d$ with the same velocity, describing the parabola A $v$ B.

From this very simple construction, we may draw several very instructive corollaries.

*Cor.* 1. When the vertical line passing through B cuts the circle EDA, it always cuts it in two points D and $d$, giving two directions AD and A $d$, either of which will solve the problem.

*Cor.* 2. But if the vertical through $b$ only touch the circle, as it touches it in one point only, it gives but one direction, along which the body must be projected to hit the mark $b$. This direction is AG.

*Cor.* 3. The direction AG evidently bisects the angle EAB, and the directions AD and A $d$ are equidistant from the middle direction AG.

*Cor* 4. If the vertical passing through B do not meet the circle described on AE, according to the conditions specified, the object is too remote to be struck by a body projected from A with the velocity acquired by falling from F. There is no direction that will enable it to go so far on the line AB. The distance A $b$ is the greatest possible with this velocity, and it is attained by taking the elevation AG which bisects the angle EAB. We may therefore call A$b$ the *maximum range* on the line AB, and AG the *middle direction.*

*Cor.* 5. The distances on a given line of position to which a body will be projected in a given direction AD, are proportional to the squares of the velocities of projection. For the figure being similar, the range AB has the same proportion to AF, the fall necessary for acquiring the velocity. Now the falls are in the duplicate ratio of the velocities required by falling. Therefore, &c.

The converse of this problem is solved with the same facility of construction.

Let a body be projected in the direction AD, with the velocity acquired by falling through FA, it is required to find to what distance it will reach on the line AB.

Describe, as before, on AE, $=$ 4 AF, the circle EDA, touching AB, and cutting AD in D. Through D draw the vertical DB, cutting AB in B. Then B is the point to which the projectile will reach. The proof is too evident to need discussion.

Lastly, suppose the object B to be given, and also the line of direction AD (which is a very common case, seeing that our mortars are often so fixed in their beds that their elevation can be very little altered) it is required to determine the velocity that must be given to the projectile.

Draw through the object the vertical BD, meeting the direction in D. Draw the vertical AE, and make it a third proportional to DB and DA, that is, make $AE = \frac{DA^2}{DB}$, and take $FA = \frac{EA}{4}$. Then FA is the fall which will generate the velocity required for the projection. The demonstration of this is also very evident.

Notwithstanding the great simplicity of the construction of these problems, we cannot obtain numerical solutions for practice with equal simplicity, except when the line of position is horizontal, as in Fig. 2. This indeed is the most general case, and there are few situations so abrupt as to deviate very far from this case, the greatest height of a fortress commonly bearing but a small proportion to the distance of the mortar.

When AB is a horizontal plane, as in Fig. 2. the arch EDA is a semicircle.

In this case the maximum range A $b$ is equal to AC, the radius of the circle, and equal to twice the height FA necessary for acquiring the velocity of the projection. This greatest range is obtained by elevating the mortar 45 degrees from the horizon.

The ranges with different directions, are proportional to the sines of twice the angles of elevation. For drawing GC, DL, $dl$, perpendicular to EA, and drawing the radii CD and C$d$, we have CG equal to the range A $b$, and $l\,d$ equal to the range AB. Now CG is the sine of the angle ACG, which is double of GAB, and $l\,d$ is the sine of AC$d$, which is double of AE$d$, which is equal to the elevation $d$AB; and the same is true of all other elevations. We may always employ this analogy as radius to the sine of twice the angle of elevation, so is twice the height necessary for acquiring the velocity to the range of the projection on a horizontal plane.

The height to which the projectile rises above the horizontal plane is as the square of the sine of elevation. For OV, the axis of the parabola, is $\frac{1}{4}$th of DB or LA;—and FA, the height to which the projectile would rise straight upwards, is $\frac{1}{4}$th of EA. Now EA : LA$=$EA$^2$: AD$^2$$=$rad.$^2$: sin.$^4$ AED,$=$rad.$^2$ sin.$^2$ elevation. Therefore FA : VO$=$rad.$^4$ : sin.$^2$ elevation; also VO : $v$ O$=$sin.$^2$ DAB : sin.$^2$ $d$AB, &c.

The times of the flights are as the sines of the elevation. For the velocities in the directions AD, A $d$, being the same, the times of describing AD and A $d$ uniformly will be as AD and A $d$. Now AD and A $d$ are as the sines of the angles AED and AE $d$, which are equal to the angles DAB and $d$AB. Now the times of describing AD and A $d$ uniformly with the velocity of projection, are the same with the times of describing the parabolas AVB and A $v$ B.

When the object to be struck is on an inclined plane, AB, ascending, as in Fig. 3. the arch EDA is less than a semicircle; and when it is on a descending plane, as in Fig. 4. EDA is greater than a semicircle. This considerably embarrasses the process for obtaining the direction, when the impetus and the object are given, or conversely. It has been much canvassed by the many authors who deliver theories of gunnery, and the parabola affords many very pretty methods of solving the problem. Dr Halley's, in the *Philosophical Transactions*, No. 179, is peculiarly elegant. Mr Thomas Simpson's also, in No. 486, is extremely ingenious and comprehensive, and has been reduced to a very elegant simplicity by Frisius in his *Cosmographia*. But neither of these methods shew so distinctly the connection between the different circumstances of the motions, or keep the general principle so much in view, as the one here given; and all the arithmetical operations which finally result from them, are precisely similar to those deduced from our construction.

The following method, suggested by the simple construction now given, is probably as easy and as expeditious as any.

Draw the horizontal line HA $a$, Fig. 3. and 4. cutting the vertical drawn through B in K; let C be the centre of the circular arch EDA. Join AC, and draw GC, cutting the verticals through A and B in the points $f$ and $g$. Also draw CD and C $d$. Let $p$ represent the angle of position EAB, and $d$ the angle of direction DAB, which the axis of the piece makes with the line of position AB. Also let $z$ be the angle EAD which the axis makes with the vertical. Let $r$ express the range AB, and $f$ the fall FA necessary for communicating the velocity of projection. Then the parameter of the parabola at the point of projection is $4f$, $=$AE, and using S to express the sine,

We have AB : DB$=$S, EAD : S, DAB,$=$S, $z$ : S, $d$.
DB : DA$=$S, DAB : S, DBA,$=$S, $d$ : S, $p$.
DA : AE$=$S, DEA : S, EDA,$=$S, $d$ : S, $p$.
Therefore AB : AE$=$S, $z\times$S, $d$ : S$^2$, $p$.
That is $r : 4f=$S, $z\times$S, $d$ : S$^2$, $p$.
And $r\times$S$^2$, $p=4f\times$S, $z\times$S, $d$.

Hence are derived formulæ, which solve all the questions contained in the problem.

$$\text{I. } r=\frac{4f\times \text{S}, z\times \text{S}, d.}{\text{S}^2, p.}$$

$$\text{II. } f=\frac{r\times \text{S}^2, p.}{4\,\text{S}, z\times \text{S}, d.}$$

$$\text{III. S}, d=\frac{r\times \text{S}^2, p.}{4f\times \text{S}, z.}$$

The answers to these questions expressed in the two first cases are obtained by a single operation. In the first case, the maximum value of $r$, which corresponds with the elevation AG, is a third proportional to AE and AD, and will be had by the analogy sin.$^2\,p$ : sin. $\frac{1}{2}p=4f : r$.

We also may remark, that the ranges made with the same velocity, and on the same declivity, are as the products of the sines of $d$ and of $z$.

But these formulæ do not afford so ready an answer, when $d$ is the thing wanted, as one would expect from their simplicity. When $d$ is unknown, $z$ is also unknown. In this case we must remark, that S, $z\times$S, $d$ is equal to $\frac{\cos.\,\overline{z\backsim d}-\cos.\,\overline{z+d}}{2}$, and that $z+d=p$.

This changes our formula into $r\times\sin.^2 p=4f\times\frac{\cos.\,\overline{z\backsim d}-\cos.\,\overline{z+d}}{2}$,$=2f\times\overline{\cos.\,z\backsim d-\cos.\,p}$,$=2f\times\cos.\,\overline{z\backsim d}-2f\times\cos.\,p$. Therefore we have

$$r\times\sin.^2 p+2f\times\cos,\,p=2f\times\cos.\overline{z\backsim d}.$$

Having obtained the arch $z\backsim d$, and having $z+d=p$, we easily obtain $d$, it being $=\frac{p+z\backsim d}{2}$. The process is much expedited by the help of a table of natural sines. We must remember, that when the projection is made on an ascending plane, the quantity $2f\times\cos.\,p$, is to be added to $r\times\sin.^2 p$; but that it is to be subtracted from it if the projection is made on a declivity.

But a plainer method may be taken, although not so obviously deduced from the general principle. The position of the object B being known, its horizontal distance AK is known. Call this $h$. The middle direction AG is also known. The line $f$ A is also known, being $=2f$. Now $f$ C$=2f\times$ tan. $f$ AC, $=2f\times$ cotan. $p$. Call this $b$. Then C $g$ is $=h+b$, or $=h-b$, according as the projection is made on an ascending or a descending plane. Now we have

$$f\text{A} : \text{C}\,g=\cos.\,\text{p} : \cos.\,\overline{d-z}, \text{ or}$$
$$2f : h\pm b=\cos.\,p : \cos.\,\overline{d-z}.$$

Then to $\frac{1}{2}p\,(=\frac{1}{2}\overline{d+z})$ add $\frac{1}{2}\overline{d-z}$, and we obtain $d$.

This is, in fact, the process to which we are ultimately led by every method that is taken for the solution of this case of the problem.

The construction suggests another process, which may be more acceptable to some readers. The angle $f$AG is $\frac{1}{2}$ EAB. Therefore $f$G$=2f\times$ tan. $\frac{1}{2}p$, and $2f\times$ tan. $\frac{1}{2}p$—

AK$=g$ G, = the versed sine of $z \propto d$, CA, or $\frac{2f}{\sin. p}$ being radius.

There are two questions more that must be solved before the artillerist can have all the information he requires. In throwing of shells, it is of peculiar importance that the fuse of the shell burn during the whole time of the flight, but no longer; and it would be best of all, were it ended when the shell is about six feet from the ground. This requires an exact knowledge of the time of the flight.

The time of the flight is the same with that of falling through DB. We must therefore calculate DB in feet.

Then $t = \frac{\sqrt{DB}}{4}$; $t^2 = \frac{DB}{16}, = \frac{r \times \sin. d}{16 \sin. z}$. From the sum of the logarithms of the range (measured in feet) and the sine of the direction, take the sum of the logarithm of 16 and the sine of the zenith distance, and half the remainder is the time of the flight, measured in seconds.

If the best or middle direction had been chosen, which is generally not far from being the case, DB is equal to BA or $r$. Therefore in this case we have $t = \frac{\sqrt{r}}{4}$.

Lastly, with respect to the velocity and momentum with which the projectile makes its stroke, this is easily deduced from the property of the parabolic motion. We know the velocity of projection, or the velocity at A, namely, that which is acquired by falling through FA. In like manner, the velocity at B is that acquired by falling through F $\alpha$, (B $\alpha$ being drawn parallel to the horizon). Therefore, $\sqrt{FA} : \sqrt{F\alpha}$ = velocity at A : velocity at B.

## CHAP. II.

### *On the Determination of the Initial Velocity of Projectiles from the explosive force of Gunpowder.*

In our article Gunpowder, we have already noticed Mr Robins' investigations respecting the explosive force of gunpowder, and we have suggested some important corrections upon the data which he employed. We shall now proceed to give an account of the solution of the important problem of determining the initial velocity of a ball, when the elasticity of the powder at the instant of its firing is given, and when the density of the ball, the quantity of the charge, and the dimensions of the piece of artillery from which it is thrown, are known.

The solution of this problem depends upon the two following principles.

1. That the action of the powder upon the ball ceases as soon as it is out of the piece.

2. That all the powder is converted into an elastic fluid before the ball is sensibly moved from its place.

The first of these principles is sufficiently manifest from the consideration, that the flame will very suddenly extend itself in every direction when it reaches the mouth of the gun, and therefore its force on the bullet will be completely extinguished.

The second principle, though less obvious, is equally certain. If the powder was fired successively, and not all at once, it occurred to Mr Robins, that by using two or three bullets instead of one, a greater quantity of powder would be fired, since a heavier weight would require a longer time to pass through the barrel. Hence two or three balls should be impelled with a much greater force than one. This, however, is by no means the case. Mr Robins found, from experiment, that the velocities with which different numbers of balls were discharged were reciprocally in the subduplicate ratio of the number of balls; that is, if one ball was discharged with a velocity of 1700 feet per second, the same charge would impel two balls with a velocity of from 1250 to 1300 feet per second, and three balls with a velocity of from 1050 to 1110. But when bodies, containing different quantities of matter, are successively impelled through the same space, with the same power acting at each point of that space with a given force, then the velocities communicated to these different bodies should be reciprocally in the subduplicate ratio of their quantities of matter. Hence, since the velocities are in the subduplicate ratio of the number of balls, the action of the powder must, in all these cases, have been nearly the same, and consequently the truth of the principle is established.

Let us now suppose that AB, Plate CCLXXXVI. Fig. 5. is the axis of the gun, DCGE the part of the cavity filled with powder, and that the hinder surface of the ball lies at GE. Then if we take FH to represent the force with which the ball is impelled at the point F, and if through H we draw an hyperbola KHNQ to the asymptotes AI, AB forming a right angle, the ordinate MN will represent the force with which the ball is impelled at M; for since the densities of the elastic fluid at the points F and M are as AM to AF, or as FH to MN, the forces will be in the same ratio. Take EL to FH as the force which impels the ball at F is to the weight of the ball, and draw LP parallel to EB. Then the equal lines LF, RM, &c. will be to the corresponding ordinates FH, MN as the gravity of the ball is to the force with which it is impelled at the points F and M. But by Prop. 39. Book I. of Newton's *Principia*, the areas FLPB, FHQB are as the squares of the velocities which the ball would acquire when acted upon by its own gravity through the space EB, and when impelled through the same space by the force of the gunpowder. Hence we shall have

$$V = \sqrt{\frac{FHQB \times (\text{Vel. of falling through FB})^2}{FLPB}}$$

If we therefore put

V = velocity of the ball.
L = length of the charge of powder.
B = length of the bore AD.
S = specific gravity of the ball.
D = the diameter of the bore, and
W = the weight of the ball in ounces, we shall have

$$V = 27130\sqrt{\frac{10\,L}{SD} \times \text{Log.}\frac{B}{L}}, \text{ or}$$

$$V = 100\sqrt{\frac{223\,LD^2}{W} \times \text{Log.}\frac{B}{L}}.$$

Thus making L = $2\frac{5}{8}$ inches.
B = 45 inches.
S = 1.345 for a leaden ball.
D = $\frac{3}{4}$ of an inch.

Then we shall have

$$V = 27130\sqrt{\frac{7}{2269} \times \text{Log.}\frac{120}{7}} = 1674$$ for the velocity of the ball per second; or if the weight of the ball W = $1\frac{9}{20}$ oz. or $\frac{29}{20}$ oz. then,

$$V = 100\sqrt{\frac{1115 \times 189}{29 \times 32} \times \text{log.}\frac{120}{7}} = 1674$$ feet, as formerly.

Having thus determined theoretically the initial velocities of projectiles, Mr Robins was anxious to compare his theory with experiment. He was thus led to the invention of the ballistic pendulum, by which the real velocities may be measured with such a degree of exactness, that in a velocity of 1700 per 1″, the error will never exceed the 500th part.

## CHAP. III.

*On the Methods of determining experimentally the Velocities of Projectiles at any Distance from the Gun from which they are discharged.*

The ballistic pendulum, which Mr Robins invented for measuring the initial velocity of projectiles, is shewn in Plate CCLXXXV. Fig. 12. where ABCD represents the body of the machine consisting of three poles B, C, D, joined at A. On the sockets R, S, screwed upon two of these poles, rests the horizontal axis EF, which suspends a pendulum GHIK, made of iron, with a broad surface at its extremity. A thick piece of wood GHIK is fastened by screws to the broad surface of the iron. A little below the bottom of the pendulum is a brace OP, joining the two poles B, C; and on this brace is fastened a contrivance MNU, made somewhat like a drawing pen, with two edges of steel, bearing on each other in the line UN, the pressure of these edges being regulated by a screw Z. To the bottom HI of the pendulum is fastened a narrow ribbon LN, which passes between the steel edges, and which hangs losely down, as at W, through an opening cut in the lower piece of steel.

Dr Hutton made some considerable improvements on the ballistic pendulum. At first he used a narrow tape, divided into inches and tenths, to which he adapted a contrivance different from that of Mr Robins. From the bottom of the pendulum proceeded a tongue of iron, which was raised or depressed by means of a screw. This tongue was cloven at the bottom to receive the end of the tape, and the tips were pinched together by a screw. Immediately below this, the tape was passed between two slips of iron, which could be brought to any degree of approach by two screws. These pieces were made to slide vertically up and down a groove in a heavy block of wood, and could be fixed at any height by a screw.

This method of measuring the chord of the arc of vibration by the tape was however often attended with uncertainty; and Dr Hutton adopted the following simple contrivance. He took a block of wood, having its upper surface formed into the arc of a circle of nearly the same radius as the extreme length of the pendulum. In the middle of this arch was a shallow groove three or four inches broad, running along the middle of the block through its whole length. This groove was filled with a composition of soft soap and wax, of about the consistency of honey, or a little firmer, having its upper side smoothed off with the general surface of the broad arch. A sharp spear proceeded from the bottom of the pendulum, so as just to enter and scratch the surface of the composition in the groove, without having its motion sensibly retarded. From the trace which was thus left, the length of the cord of the arc of vibration was easily measured.

The pendulum being thus constructed, is used in the following manner. The ball is discharged against the block of wood GHIK, which in consequence of the impulse, vibrates through an arc of a certain extent, which of course increases with the velocity of the ball. The extent of the arc of vibration is measured by the length through which the ribbon LN is pulled out through the edges UN. Hence, if the weight of the pendulum is known, and also the distance of its centre of gravity and oscillation from its axis of suspension, it is easy to determine the extent of the arc of vibration, the velocity with which it is struck by a body of a known weight entering it at a given point. In the investigation of the theorem for computing the velocity of the ball, Mr Robins committed a trifling mistake, which he corrected in the *Philosophical Transactions* for 1743, but which the editor of his works omitted to insert in the New Principles of Gunnery published in 1761. The theorem of Robins is

$$v = \frac{c}{r} \times \frac{pg}{bi} + \frac{i}{o} \times \frac{o}{\sqrt{2i}}$$

The theorem as corrected by Euler, is

$$v = \frac{c}{r} \times \frac{pg}{bi} + \frac{o+i}{2o} \times \sqrt{\frac{o}{2}}$$

The formula given by Antoni is

$$v = c\sqrt{32.18 \times \frac{\overline{pgo + bi^2} \times \overline{pg + bi}}{bir}}$$

which is $v = 5.6727c\sqrt{\frac{\overline{pgo + bi^2} \times \overline{pg + bi}}{bir}}$

The formula given by Dr Hutton is

$v = \frac{5.6727c}{bir}\sqrt{\overline{pgo + bii} \times \overline{pg + bi}}$, almost the same as Antoni's, which he reduces to the following very simple formula:

$$v = 5.6727gc\,\frac{p+b}{bir}\sqrt{o},$$

which is within $\frac{1}{5000}$dth part of the true quantity, and will always give the velocity within less than half a foot, even when the velocities are greatest. In these formulæ,

$v$ = the initial velocity of the ball at the instant of impact.

$b$ = weight of the ball.

$p$ = weight of the pendulum.

$g$ = distance to its centre of gravity.

$o$ = the distance of its centre of oscillation.

$i$ = the distance to the point of impact, or the point struck by the ball.

$c$ = the chord of the arch of vibration.

$r$ = its radius or distance to the ribbon.

The machine of Mattei for measuring initial velocities near the mouth of the gun, which we have already briefly described, was employed by Antoni. It consists of a horizontal wheel AB, mounted upon a vertical axis, and put in motion by the descent of a weight Q suspended to the rope GG, and which can be raised into a state of activity by the winch fixed to the axis of the pulley P. A circular band of writing paper AE, BF, about six inches high, is fixed round the circumference of the wheel AB, so as to form a drum 10 feet in diameter. A butt or block of elm is placed about two or three feet from the drum to receive the balls. The gun being fixed immoveably at the distance of 20 feet, so that its axis produced would pass through an exact diameter of the drum perpendicular to GG, the machine is put in motion by the descent of the weight Q. The motion soon becomes uniform, and the velocity of the drum is measured by a small eccentric wheel IL upon the axis CD, which at every revolution gives a vibratory horizontal motion to a tongue of wood, at the extremity of which is suspended a common pendulum, which is shortened or lengthened till its vibrations are isochronous to those of the tongue. The time in which the wheel performs a revolution will be shewn by the length of the pendulum. When the pendulum and the tongue have acquired an isochronous motion, the gun is discharged, and the wheel stopped. The hole made in the drum at the first entrance of the ball will be easily distinguished from the other hole which is made at its exit, by the edges of the holes being turned to the point by which the ball went out of the drum. A thread is then stretched in the direction in which the ball was fired, so as to pass through the centre of the first hole, and the point where the line cuts the drum is marked. The distance between this mark and the second hole is the distance through which the circumference of the drum has moved while the projectile was passing through a space equal to its diameter.

In order to find the uniform velocity of the shot in a second of time, call $d$ the diameter of the wheel, $c$ its circumference, $t$ the time in which the wheel performs one revolution, $m$ the distance through which a part of the circumference of the drum moves while the ball is traversing the distance D, and $v$ the initial velocity of the shot in a second of time: then $m : d = c : \frac{cd}{m}$ = the space passed through by the shot with a uniform velocity during one revolution of the wheel: then as $t : 1 = \frac{cd}{m} : \frac{cd}{tm} = v$.

In using this machine, Antoni used wads of parchment torn in several places, that they might not injure the drum of paper. An account of the experiments themselves will be given in the next Chapter.

Antoni has given an account of other three methods of measuring the initial velocities of projectiles. The first consists in measuring their respective penetrations into a homogeneous butt of a known consistency. If we call $b$ the consistency of the butt, $d$ the diameter of the shot, $p$ the depth of its penetration, and $v$ the initial velocity, we shall have $v = \sqrt{\frac{bp}{d}}$. In order to find $b$, the consistency of the butt, fire a piece of small calibre, with an iron shot one inch in diameter, and measure its initial velocity by the methods already described, and let it be 1000 feet, then $v = 1000$. Let the same piece be then loaded as before, and fired into the butt, and let its penetration be 12 inches, or 1 foot, $= p$. Then, since $bp = dv^2$, we shall have $p \times 1 = \frac{1}{12} \times 1000^2$, or $p \times 83333$. Substituting then, in the formula, $bp = dv^2$, we have $83333\,p = dv^2$. The consistency of the butt being thus found, place the great gun, the initial velocity of whose shot is required, and having fired several rounds in a horizontal direction against the butt, let the mean of the different depths of penetration be $7 = p$, and let $d$, the diameter of the shot, be equal 4 inches, then we have $83333 \times 7 = \frac{4}{12} v^2$, and $v =$

$$\sqrt{\frac{83333 \times 7 \times 12}{4}} = 1323,$$ the initial velocity required.

The second method proposed by Antoni of determining initial velocities, consists in analysing and resolving into its simple movements the curve described by the projectile on quitting the piece. In order to effect this, a gun AB, Plate CCLXXXVI. Fig. 7, mounted on its carriage, and laid on an even and solid platform, is placed with its axis in a horizontal direction AC, so that the shot, at its first graze, may touch the earth in the point C of the horizontal line DF. The vertical distance KG is obviously the space through which the shot has descended by the action of gravity, which may be called $s$, and the horizontal distance AK or DG is the space which it has passed through in the same time, in virtue of the impulsive or projectile force. Then since $s = \frac{32.18\,t^2}{2}$, and $t = \sqrt{\frac{2s}{32.18}}$, we have, by substituting KG for $s$, $t = \sqrt{\frac{2\,KG}{32.18}}$ = the time in which the shot is impelled from A to K. Having obtained DG accurately from the mean of several trials, call it $r$, and considering it as uniformly passed over, say, as $t : r = 1 : \frac{r}{t}$, the initial velocity, or the space through which the shot would move in a second, without considering the air's resistance. Let KG = four feet, then we have $t = \sqrt{\frac{2 \times 4}{32.18}} = \frac{1}{2}$ a second; and if DG = 700 feet, we have $\frac{r}{t}$, or $v = \frac{r}{\sqrt{\frac{2 \times 4}{32.18}}} = 1400$ feet, the initial velocity required.

As the initial velocity thus determined is not absolutely correct, on account of the resistance of the air, a more accurate result may be obtained, by placing a butt LMN nearer the gun. Let a line be drawn on the butt at M, where it is cut by the horizontal line of direction AM, and by firing several shot at the butt, the vertical distance MH = $s$ will be ascertained. By measuring the distance DL, and using the formulæ already given, the initial velocity $v$ will again be found. The nearer the gun is brought to the butt, the more correct will the initial velocity be found. Both these methods may be applied to guns of all lengths and calibres.

The third method of determining initial velocities is, by deducing them from the thickness of the metal of the fire arm when it is in equilibrio with the pressures of the elastic fluid in every point of its length. This method, however, is not applicable to guns of large calibre fired with the common charges of powder, but only to fusils and pieces of small calibre. Antoni informs us, that in Piedmont musket barrels are proved, by charging them with 17 drachms of common cannon powder, over which is put a very high wad of hard tow, which is with difficulty pressed into the barrel, and which is afterwards rammed down with all the force which the armourer can exert. A leaden bullet, weighing $18\frac{1}{2}$ drachms, is then put in, and wadded as before. The barrels being placed with their breech upon a strong beam of wood, are each fired twice. Many of them burst, sometimes at the breech, and sometimes in the middle of the bore, and sometimes near the muzzle; but as the bursting never happened more frequently on one part than another, the officers and manufacturers did not consider it as necessary to make any change in the thickness of the metal. Hence in guns of this kind, the thickness of the metal may be considered as proportional to the pressure of the elastic fluid in every part of their length.

As this method is not likely to be of much use, we shall merely refer the reader to Antoni's *Treatise on Gunpowder*, translated by Thomson, p. 87, 88, 165, &c.

## CHAP. IV.

*Comparison of the Initial Velocities of Bullets, as computed from the Theory, with the actual Velocities, as determined by the Ballistic Pendulum.*

In determining the initial velocity of bullets, Mr Robins used a musket barrel, nearly as thick at the muzzle as at the breech, and its thickness was made equal to the diameter of its bore. It was always charged with a ladle, as in the case of cannon, and the wadding was never greater than was necessary to confine the powder to its proper place. In order to prevent the impulse of the flame from acting upon the pendulum, the mouth of the musket should be sixteen or eighteen feet from it, when the charge is half an ounce of powder. With larger charges, Mr Robins has often found the impulse to be sensible at the distance of twenty-five feet.

His first set of experiments was made with a musket 45 inches long; the diameter of the ball was $\frac{3}{4}$ths of an inch, and the cavity containing the powder was $2\frac{5}{8}$ inches, which, as the barrel exceeded the bullet by about the 40th of an inch, contained exactly 12 penny-weights of powder. This barrel we shall call A.

The weight of the whole pendulum was 52 lb. 3oz. The distance of the centre of gravity from the axis of suspension was 52 inches; 200 of its small swings were performed in 253 seconds, and therefore the distance of its centre of oscillation from the axis of suspension, was $62\frac{2}{3}$ inches.

The following results were obtained with this pendulum and the barrel A.

| Number of experiments. | Barrel employed. | Quantity of Powder. | Chord of its Ascending Arch measured on the Ribbon. | The same by the Theory. | Error of the Theory. |
|---|---|---|---|---|---|
| | | Dwts | | | |
| 1 | A | 12 | 18.7 | 19.0 | +.3 |
| 2 | A | 12 | 19.6 | 19.0 | —.6 |
| 3 | A | 6 | 13.6 | 13.4 | —.2 |

Another set of experiments was made with the same barrel, but with a pendulum exceeding a little the weight of 56 lb. 3 *oz.* and the following results were obtained.

| Number of Experiments. | Barrel employed. | Length of the Cavity containing the Powder, or Line AF in Fig. 5. | Quantity of Powder. | Chord of the Ascending Arch measured on the Ribbon. | The same by the Theory. | Error of the Theory. |
|---|---|---|---|---|---|---|
| | | Inches. | Dwts | Inches. | Inch. | Inches. |
| 4 | A | $2\frac{5}{8}$ | 6 | 11.9 | 12.1 | +.2 |
| 5 | A | $2\frac{5}{8}$ | 6 | 12.2 | 12.1 | —.1 |
| 6 | A | $1\frac{1}{4}$ | 6 | 13.2 | 13.6 | +.4 |
| 7 | A | $1\frac{1}{4}$ | 6 | 13.9 | 13.6 | —.3 |
| 8 | A | $2\frac{5}{8}$ | 12 | 16.7 | 17.2 | +.5 |
| 9 | A | $2\frac{5}{8}$ | 12 | 17.5 | 17.2 | —.3 |
| 10 | A | $2\frac{5}{8}$ | 12 | 16.9 | 16.8 | —.1 |
| 11 | A | $2\frac{5}{8}$ | 12 | 17.0 | 16.8 | —.2 |
| 12 | A | $2\frac{5}{8}$ | 6 | 11.7 | 11.5 | —.2 |
| 13 | A | $2\frac{5}{8}$ | 6 | 11.1 | 11.5 | +.4 |
| 14 | A | $2\frac{5}{8}$ | 12 | 16 7 | 16.3 | —.4 |

In calculating the theoretical results for the experiments 10—14, an allowance was made for the quantity of bullets lodged in the board, which increased the weight of the pendulum.

The next experiments made by Mr Robins were with another barrel C, which had the same bore with the last, but which was only 12.375 inches long. The pendulum was rather lighter than 56 lb. 3 oz.

| Number of Experiments. | Barrel Employed. | Extent of the cavity containing the Powder. | Quantity of Powder. | Chord of the ascending Arch measured on the Ribbon. | The same by the Theory. | Error of the Theory. |
|---|---|---|---|---|---|---|
| | | Inches. | Dwts. | Inches. | Inches. | Inches. |
| 15 | C | $2\frac{5}{8}$ | 12 | 12.7 | 12.8 | +.1 |
| 16 | C | $2\frac{5}{8}$ | 12 | 12.6 | 12.8 | +.2 |
| 17 | C | $2\frac{5}{8}$ | 12 | 12 4 | 12.8 | +.4 |
| 18 | A | $2\frac{5}{8}$ | 12 | 17.0 | 17.3 | +.3 |
| 19 | A | $2\frac{5}{8}$ | 12 | 17.2 | 17.2 | .0 |
| 20 | A | $2\frac{5}{8}$ | 12 | 17.1 | 17.2 | +.1 |
| 21 | A | $2\frac{5}{8}$ | 12 | 17.2 | 17.2 | .0 |
| 22 | A | $2\frac{5}{8}$ | 6 | 12.4 | 12 2 | +.2 |

Another barrel B, of the same bore with A and C, but 24.312 inches long, was now used, with a pendulum a little heavier than 56 lb. 3 oz. A correction was made for the increase of weight, as formerly.

| Number of Experiments. | Barrel employed. | Extent of the Cavity containing the Powder. | Quantity of Powder. | Chord of the ascending Arch measured on the Ribbon. | The same by the Theory. | Error of the Theory. |
|---|---|---|---|---|---|---|
| | | Inches. | Dwts. | Inches. | Inches. | Inches. |
| 23 | A | $2\frac{5}{8}$ | 12 | 17.1 | 17.2 | +.1 |
| 24 | A | $2\frac{5}{8}$ | 9 | 15.2 | 15.0 | —.2 |
| 25 | A | $2\frac{5}{8}$ | 9 | 15.4 | 15.0 | —.4 |
| 26 | C | $2\frac{5}{8}$ | 12 | 11.5 | 12.8 | +1.3 |
| 27 | C | $2\frac{5}{8}$ | 12 | 11.5 | 12.8 | +1.3 |
| 28 | C | $2\frac{5}{8}$ | 6 | 8.7 | 9. | +.3 |
| 29 | C | $2\frac{5}{8}$ | 12 | 12.3 | 12.5 | +.2 |
| 30 | B | $2\frac{5}{8}$ | 12 | 14.4 | 14.4 | 0.0 |
| 31 | B | $2\frac{5}{8}$ | 12 | 14.4 | 14.4 | 0.0 |
| 32 | B | $2\frac{5}{8}$ | 6 | 10.3 | 10.5 | +.2 |
| 33 | A | $1\frac{3}{4}$ | 8 | 14.7 | 14 5 | —.2 |
| 34 | A | 4 | 12 | 15.7 | 15.3 | —.4 |

Mr Robins suspects, that in experiments 26 and 27 a mistake had been made in the weight of the powder, or that the barrel had been damp.

Another barrel D was now used, 7.06 inches long, and 0.83 in diameter. Its bullet, which weighed $33\frac{1}{2}$ dwts. was exactly fitted to the bore without any windage, so that it went in with difficulty.

| No. of Expts. | Barrel Employed. | Length of the Cavity containing the Powder. | Quantity of Powder. | Chord of the ascending Arch measured on the Ribbon. | The same by the Theory. | Error of the Theory. |
|---|---|---|---|---|---|---|
| | | Inches. | Dwts. | Inches. | Inches. | Inches. |
| 35 | A | $2\frac{5}{8}$ | 12 | 9.2 | 9.2 | .0 |
| 36 | A | $2\frac{5}{8}$ | 12 | 9 5 | 9.2 | —.3 |
| 37 | A | $5\frac{1}{4}$ | 24 | 11.7 | 11.3 | —.4 |
| 38 | A | $7\frac{7}{8}$ | 36 | 13 2 | 12.6 | —.6 |
| 39 | A | $2\frac{5}{8}$ | 12 | 9.3 | 9.1 | —.2 |

| 55 | D | $2\frac{5}{8}$ | 6 | 4.7 | 4.8 | +.1 |
| 56 | D | $2\frac{5}{8}$ | 6 | 4.8 | 4 8 | .0 |
| 57 | A | $2\frac{1}{16}$ | 6 | 6.4 | 6.5 | +.1 |
| 58 | A | $2\frac{1}{16}$ | 6 | 6 4 | 6.5 | +.1 |
| 59 | A | $2\frac{1}{16}$ | 6 | 6.6 | 6.5 | — 1 |
| 60 | A | $2\frac{1}{16}$ | 6 | 6 7 | 6.5 | —.2 |
| 61 | A | $2\frac{1}{16}$ | 12 | 9 0 | 9.1 | +.1 |

Mr Robins supposes, that the error in the 50th experiment was owing to the wind. All the preceding experiments were made and registered, before they were compared with the theory.

A set of valuable experiments on the initial velocities of bullets were made by Antoni, with the machine invented by Mattei.

The first series was made with a musket 3 feet 6 inches in the length of its bore, and with a charge of powder of 7 drams.

| Nature of the Powder. | Moist Weather. | Mean state of the Atmosphere. | Very dry Weather. |
|---|---|---|---|
| | Feet. | Feet. | Feet. |
| Common war powder | 1392 | 1542 | 1618 |
| Fine do. | 1569 | 1736 | 1829 |
| Fowling powder | 1566 | 1703 | 1784 |
| Firework powder | 1566 | 1706 | 1779 |

The following experiments were made under a mean state of the atmosphere, with guns of different lengths and calibres.

| Nature of the Guns. | Kind of Powder. | Weight of Powder. | Initial Velocity. |
|---|---|---|---|
| A musket with a bore 1 ft. 10 inch. long | Fine war powder | 7 | 1390 |
| | Fowling do. | 7 | 1367 |
| | Firework do. | 7 | 1372 |
| Rifled carabine | Fine war powder | 7 | 1956 |
| | Fowling do. | 7 | 1920 |
| | Firework do. | 7 | 1934 |
| A wall-piece carrying a leaden bullet $2\frac{1}{2}$ oz. in weight | Fine war powder | 20 | 1956 |
| | Fowling do. | 20 | 1928 |
| | Firework do. | 20 | 1923 |
| A musket with a bore 3 ft. 6 inch. long | Fine war powder | 7 | 1736 |

In order to ascertain the effect produced by a difference in the weight of shot, and in the windage, three bullets were fired from a wall-piece, and two from the musket 3 feet 6 inches in length of bore.

| Weight of Balls. | | Quantity of fine War Powder. | Initial Velocities. |
|---|---|---|---|
| Wall-piece | $3\frac{1}{2}$ oz. | 23 drams | 1770 |
| | 3 | 23 | 1855 |
| | 3 oz. but of the same diameter as the first ball | 23 | 2068 |
| Musket | 1 oz. | 7 | 1736 |
| | $\frac{7}{8}$ | 7 | 1834 |
| | Carabine ball. | 7 | 1863 |

The following experiments were made in a mean state of the atmosphere, to shew how the initial velocities vary with different charges of fine war powder:

| Weight of Powder in drams. | | Initial Velocities. |
|---|---|---|
| Musket with a bore 3 ft. 6 in. | 5 | 1399 |
| | 7 | 1736 |
| | 10 | 1984 |
| Wall-piece with a bullet $2\frac{1}{2}$ oz. | $11\frac{1}{2}$ | 1504 |
| | 18 | 2056 |
| | 25 | 2060 |

The following results were obtained with four muskets of different lengths. The ball was 1 oz. in weight, and the charge was seven drams of fine war powder:

| Length of Barrel from the Ball to the Muzzle. | | Initial Velocities. |
|---|---|---|
| Feet. | Inches. | |
| 0 | 11 | 1037 |
| 1 | 10 | 1390 |
| 3 | 8 | 1736 |
| 4 | 8 | 1815 |

## CHAP. V.

### *On the Actual Ranges of Projectiles in a resisting Medium.*

Hitherto we have considered only the state of projectiles immediately after they have quitted the mouth of the gun or piece from which they have been discharged. We shall now proceed to consider the effects which are produced by the resistance of the air; and we shall again have occasion to admire the singular address with which Mr Robins has investigated this branch of the subject.

The resistance opposed to a body moving in a medium of uniform density was always considered by philosophers as proportional to the square of the velocity; that is, if a ball moved with four times the velocity in one part of its path that it did in another, the resistance to the greater velocity would be 16 times as great. Now, if we take a ball $\frac{3}{4}$ of an inch in diameter, moving with a velocity of 1600 feet in a second, it will be found, from theory, (see Newton's *Principia*, Prop. 38.), that its resistance will be $4\frac{1}{6}$ pounds avoirdupois, the weight of water being taken to that of air as 850 to 1.

In order to compare this result with experiment, Mr Robins used his ballistic pendulum, with which he could easily measure the velocity of a projectile at any point of its path. He charged a musket barrel three times in succession with a leaden ball $\frac{3}{4}$ of an inch in diameter, and with about half its weight of powder, and fired it against the pendulum at 25, 75, and 125 feet distance from the mouth of the piece respectively. The following were the results:

| Distance from the Muzzle. | Tract of air passed through. | Velocity in a second. |
|---|---|---|
| | Feet. | |
| 25 | 50 | 1670 |
| 75 | | 1550 |
| 125 | 50 | 1425 |

Hence, in passing through 50 feet of air, the bullet lost a velocity of 120 or 125 feet per second; and as it passed through that space in $\frac{1}{32}$ or $\frac{1}{30}$ of a second, the medium quantity of resistance must have been about 120 times the weight of the ball, or 10 lb. avoirdupois, since the ball weighed $\frac{1}{12}$ of a pound. It follows, therefore, that the theoretical is to the observed resistance as $4\frac{1}{6}$ to 10.

The following results were obtained with the same piece:

| Distance from the piece. | | Velocity. |
|---|---|---|
| 25 feet . . . | Medium of three trials. | 1690 |
| 175 . . . . . | Medium of five trials. | 1300 |

In this experiment, the ball lost a velocity of 390 feet in a second, in traversing 150 feet of air; and the velocity computed from these data is 11 and 12 lbs. avoirdupois, even greater than before.

The following experiments were made in smaller velocities. The same barrel, and balls of the same size, but less powder, were now used.

| Distance from the piece. | | Velocity. |
|---|---|---|
| 25 feet | Medium of five trials | 1180 |
| 250 | Medium of five trials | 950 |

The ball, therefore, in passing through 225 feet of air, lost a velocity of 230 feet in a second; and as it passed through that space in $\frac{3}{14}$ths of a second, the resistance to the middle velocity will be 2 lbs. 10 oz. avoirdupois, whereas the theoretical resistance will be only $\frac{7}{11}$ths of this.

From these experiments it is manifest, that the theory of the resistance of air in slow motions, as established by Sir Isaac Newton and others, is quite incorrect when applied to the rapid motions of military projectiles. The parabolic theory of gunnery is, therefore, in every respect erroneous. The path of military projectiles is neither a parabola, nor approaching to a parabola, unless when their velocities are very small; and instead of their path lying in the same place, it is in reality doubly incurvated, the ball being frequently driven to the right and left of its original direction by the action of some force acting obliquely to the progressive motion of the body, occasioned no doubt by the whirling motion of the shot about its axis.

In computing the paths of bodies moving rapidly through the air, Mr Robins lays down the following principles, which he has deduced from numerous experiments.

*First*, That the resistance varies as the squares of the velocities, when the velocities do not exceed 1100 feet per second; and that a 12 pound shot, moving with a velocity of 25 feet per second, is half an ounce avoirdupois. Hence we shall have its resistance for different velocities thus:

| Velocity. | Resistance. |
|---|---|
| 25 feet per second | $\frac{1}{2}$ oz. |
| 100 | 8 oz. |
| 500 | $12\frac{1}{2}$ lb. |
| 1000 | 50 lb. |
| 1700 | $144\frac{1}{2}$ lb. |

*Second*, That if the velocity be greater than 1100 or 1200* feet per second, then the resistance will be three times as great as it should have been by a comparison with the smaller velocities. Thus the 12 lb. shot above-mentioned, instead of being resisted by 144 lbs. will now suffer triple that resistance, or $433\frac{1}{2}$ lbs.

In proceeding to give an account of Mr Robins' method of computing the resistance, we must first explain the terms which he employs.

1. The *potential random* of a projectile is the horizontal distance to which it would be thrown in a non-resisting medium, at an angle of 45°. If $v$ be the initial velocity of the projectile in a second, in feet, then the potential random or $p=\frac{2v^2}{64\frac{1}{3}\text{ feet}}$, or $v=\sqrt{\frac{64\frac{1}{3}p}{2}}$ when the potential random is given.

2. The *potential range* is the horizontal distance to which the projectile would be thrown at any angle different from 45°.

3. The *actual range* is the horizontal distance to which the projectile is actually thrown.

In computing the effects of resistance, he assigns a certain quantity F, adapted to the resistance of the particular projectile. This quantity F expressed in yards, in iron shells, or bullets, is $d\times300$ when $d$ is the bullet's diameter in inches. When the bullet has a different specific gravity from iron, then F must be increased or diminished in the ratio of the specific gravities. Mr Robins then gives the three following propositions, which are suited to velocities below 1100 or 1200 feet in a second. The application of the principle to greater velocities will be shown in the corollary to Prop I.

PROP. I.

To determine the potential range, and consequently the potential random and initial velocity of a given shell or bullet, when its actual range is given, and when its elevation does not exceed 8° or 10°.

Enter the following Table with the quotient arising from dividing the actual range by F, and the corresponding number in the 2d column, multiplied by F, will be the potential range required; and as the ranges at different elevations are proportional to the sines of twice the angle of elevation, (see Chap 1. p. 177. col. 1.) the range at 45°, the potential random is also given. Then, as the velocity is that which is due to a height equal to one half of the potential random, (See p. 177.) the initial velocity is likewise given. Thus we have $v=\sqrt{\frac{64\frac{1}{3}p}{2}}$

| Actual ranges expressed in F. | Corresponding potential ranges expressed in F. | Actual ranges expressed in F. | Corresponding potential ranges expressed in F. | Actual ranges expressed in F. | Corresponding potential ranges expressed in F. |

* Mr Robins has noticed the remarkable fact, that the velocity at which the projectile begins to follow a new law of resistance, is nearly the same as the velocity of sound. It follows, however, from Dr Hutton's experiments, that there is no such *saltus* from the law of the squares of the velocities; but that the increase of the resistance above this law takes place gradually from the slowest motion, and never rises so high as to be three times that quantity.

The following examples will make this proposition easily understood. An 18 pounder, with a five inch iron shot, and a charge of 2 lb. of powder, ranged 975 yards, at an elevation of 3° 30′. In this case. $F = d \times 300 = 1500$, and $\frac{975}{1500} = 0.65$, which gives in the 2d column of the Table 0.817, consequently 0.817 F=1225 yards, equal the potential range required, which increased in the ratio of the radius to the sine of twice the angle of elevation, gives 10050, for the potential random. The original velocity is then

$$v = \sqrt{\frac{64\frac{1}{3}p}{2}} = 984 \text{ feet in } 1'',$$ where $p$ is the potential random, or 10050 yards, or 30150 feet.

In order to find the actual range from the potential range at a small angle, enter the second column of the Table with the quotient of the potential range divided by its correspondent F, there will be found opposite to it in the first column, a number which, when multiplied by F, will give the actual range required.

If the potential random deduced from the potential range exceeds 13,000 yards, then it ought to be corrected for the treble resistance already mentioned. In order to find the correct potential random, take a 4th continued proportional to 130,000, and the potential random is found by this proposition; and this 4th proportional is the potential random, corrected for the treble resistance. In like manner, when the true potential random is given greater than 13,000 yards, we must take two mean proportionals between 13,000 and this random, and the first of these proportionals must be assumed, instead of the random given in all the operations described under this proposition.

For example, a 24 pounder charged with 12 lbs of powder, ranged about 2500 yards at an angle of 7° 15′. In this case, F is 1700, and $\frac{2500}{1700} = 1.47$, opposite which, in the 2d column, is 2556, which gives the potential range 4350 yards, and the potential random 174,000; but as that is more than 13,000, we must take a 4th continued proportional to 13,000 and 17,400, which is 31,000 yards, the correct potential random required, whence the velocity is nearly 1730 feet in a second.

### Prop. II.

The actual range of a given shell or bullet, at an angle not exceeding 45°, being given, to determine its potential range at the same angle, and thence its potential random and original velocity.

Let A be the angle of elevation, then multiply F by cos. $\frac{3A}{4}$, and the product will be E corrected for the given angle. Use this corrected value of F instead of F in the way described in Prop. 1. and the potential range will be had; consequently the potential random and original velocity.

Thus a mortar charged with 30 lb. of powder, throws a shell $12\frac{3}{4}$ inches diameter, and 231 lb. weight, to the distance of 3450 yards, or two miles, at an elevation of 45°. The value of F corresponding to this shell is $12\frac{3}{4} \times 300$, or 3825 yards; but as the shell is only four-fifths of a solid globe, the true value of F will be $\frac{4 \times 3825}{5} = 3060$, which when multiplied by cos. $\frac{3A}{4}$ gives 2544 for F corrected. Now the quotient of the potential range divided by E, or $\frac{3450}{2545}$, is 1.384, which when sought in the 1st column of the Table gives 2,280, which being multiplied by corrected F, gives 5800 yards for the potential range required. This is also the potential random, as the elevation is 45°, and the original velocity of the shell will be 748 feet in a second.

In order to find the actual range from the potential range, divide corrected F by the potential range; and entering the 2d column of the Table with this quotient, the number in the 1st column multiplied into corrected F will be the actual range sought.

### Prop. III.

The potential random of a given shell or bullet being given, to determine its actual range at 45°.

Make $q$ = the given potential random divided by F corresponding to the shell or bullet.

$d$ = the difference between the tabular logarithms of 25 and of 9, the logarithm of 10 being supposed unity. Then the actual range sought will be

$$3{,}4\ F + 2\,d\,F - \frac{d^2}{10}F \text{ when } q \text{ exceeds 25, and}$$

$$3{,}4\ F - 2\ d\ F - \frac{d^2}{10}F \text{ when } q \text{ is less than 25.}$$

In this solution $q$ may be any number not less than 3, nor greater than 2500.

The following Table computed in this way shews the relation between the potential randoms and the actual range at 45°, within the limits of the proposition.

| Potential Randoms. | Actual Range at 45°. | Potential Randoms. | Actual Range at 45°. |
|---|---|---|---|
| 3 F | 1.5 F | 50 F | 4.0 F |
| 6 F | 2.1 F | 100 F | 4.6 F |
| 10 F | 2 6 F | 200 F | 5.1 F |
| 20 F | 3.2 F | 500 F | 5.8 F |
| 30 F | 3.6 F | 1000 F | 6.4 F |
| 40 F | 3.8 F | 2500 F | 7.0 F |

It is singular to observe, that so enormous are the effects of the air's resistance, that when the potential random increases from 3 F to 2500 F, the actual range increases only from $1\frac{1}{2}$ F to 7 F.

In order to examine the justness of the approximations laid down in Prop. II. and III. Mr Robins has calculated a table of the actual ranges at 45° of a projectile, resisted as the square of its velocity.

| Potential Randoms, | Actual Range at 45°. | Potential Randoms, | Actual Range at 45°. |
|---|---|---|---|
| .1 F | .0963 F | 6.5 F | 2.169 F |
| .25 F | .2282 F | 7 0 F | 2.237 F |
| .5 F | .4203 F | 7.5 F | 2.300 F |
| .75 F | .5868 F | 8.0 F | 2 359 F |
| 1.0 F | .7323 F | 8 5 F | 2.414 F |
| 1.25 F | .860 F | 9 0 F | 2 467 F |
| 1.5 F | .978 F | 9.5 F | 2.511 F |
| 1.75 F | 1.083 F | 10.0 F | 2.564 F |
| 2.0 F | 1.179 F | 11.0 F | 2 651 F |
| 2.5 F | 1.349 F | 13.0 F | 2.804 F |
| 3.0 F | 1.495 F | 15 0 F | 2.937 F |
| 3.5 F | 1.624 F | 20.0 F | 3.196 F |
| 4.0 F | 1.738 F | 25.0 F | 3.396 F |
| 4.5 F | 1.840 F | 30.0 F | 3.557 F |
| 5.0 F | 1.930 F | 40.0 F | 3.809 F |
| 5.5 F | 2.015 F | 50.0 F | 3.998 F |
| 6.0 F | 2.097 F | | |

This Table was computed by methods different from those hitherto described, and is sufficiently correct to serve as a standard with which the results of the other rules may be compared.

The following Table contains the comparison of the actual potential randoms, from trials made by Antoni on the banks of the Po, in June 1764, the barometer standing at 29 inches.

| | Initial Velocity. | Elevation. | Actual Ranges. Yards | Potential Ranges. Yards. |
|---|---|---|---|---|
| Rifled carbine, bullets weighing $\frac{1}{8}$th of an oz. | 1956 | 1°5 | 901 | 19903 |
| | | 24°. 20 | 938 | 29854 |
| | | 45° | 895 | 39806 |
| Musket, the bullet weighing one oz. | 1736 | 7°.15 | 948 | 7845 |
| | | 15° | 1305 | 15691 |
| | | 24°.20 | 1335 | 23537 |
| | | 45° | 1181 | 31383 |
| Wall-pieces. Balls weighing 3 oz. | 1855 | 15° | 1433 | 17897 |
| | | 24°.20 | 1753 | 26734 |
| | | 45° | 1629 | 35794 |
| Wall-pieces. Balls weighing $3\frac{1}{2}$ oz. | 1770 | 15° | 1699 | 16307 |
| Wall-pieces. Balls weighing 3 oz. but equal in diameter to $3\frac{1}{2}$ oz. balls. | 2068 | 15° | 1630 | 22268 |

In order to determine experimentally the curve described by projectiles, Antoni recommends the following method. Choose a piece of ground on which the guns may be placed at the different heights, A, C, D, E, and fire some rounds from A, the position and charge of the gun remaining always the same. Having marked the first graze of the shot at I, fire from C, D, F, with the same elevation, direction, and charge, and mark the grazes at L, B, and Q. (Plate CCLXXXVI. Fig. 8.) The perpendiculars IH, LK, BM, and QF, will be the abscissæ of the curve described by the shot and horizontal lines; AH, CK, DM, and EF, will be the corresponding ordinates, from which the curve may be deduced, or traced mechanically.

The same result may be obtained by firing the gun from different points of a horizontal plain against the face of a mountain.

## CHAP. VI.

*Mr Robins' Practical Maxims relative to the Effects and Management of Artillery, the flight of Shot and Shells.*

### *Maxim* I.

In any piece of artillery whatever, the greater quantity of powder it is charged with, the greater will be the velocity of the bullet.

### *Maxim* II.

If two pieces of the same bore, but of different lengths, are fired with the same charge of powder, the longer will impel the bullet with a greater celerity than the shorter.

### *Maxim* III.

If two pieces of artillery, different in weight, and formed of different metals, have their cylinders of equal bores and equal lengths; then, with like charges of powder and like bullets, they will each of them discharge their shot with nearly the same celerity.

### *Maxim* IV.

The ranges of pieces at a given elevation, are no just measures of the velocity of the shot; for the same piece fired successively, at an invariable elevation with the powder, bullet, and every other circumstance as nearly the same as possible, will range to very different distances.

### *Maxim* V.

The greatest part of that uncertainty in the ranges of pieces, which is described in the preceding maxims, can only arise from the resistance of the air.

### *Maxim* VI.

The resistance of the air acts upon projectiles in a twofold manner; for it opposes their motion, and by that means continually diminishes their celerity; and it, besides, perpetually diverts them from the regular course they would otherwise follow; whence arises those deviations and inflections mentioned in Maxim XI.

### *Maxim* VII.

That action of the air by which it retards the motion of projectiles, is in many instances an immense force; and hence the motion of these resisted bodies is totally different from what has been generally supposed.

### *Maxim* VIII.

This retarding force of the air acts with different degrees of violence, according as the projectile moves with a greater or lesser velocity; and the resistances observe this law: that to a velocity which is double another, the resistance (within certain limits) is fourfold, and to a treble velocity ninefold; and so on.

### *Maxim* IX.

But this proportion between the resistances to two different velocities does not hold, if one of the velocities be less than that of 1200 in a second, and the other greater. For in that case the resistance to the greater velocity is near three times as much as it would come out by a comparison with the smaller, according to the law explained in the last maxim.

### *Maxim* X.

To the extraordinary power exerted by the resistance of the air it is owing, that when two pieces of different borders are discharged at the same elevation, the piece of the larger bore usually ranges farthest, provided they are both fired with fit bullets, and the customary allotment of powder.

### *Maxim* XI.

The greatest part of military projectiles will, at the time of their discharge, acquire a whirling motion round their axis, by rubbing against the inside of their respective pieces; and this whirling motion will cause them to strike the air very differently from what they would do, had they no other but a progressive motion. By this means it will happen, that the resistance of the air will not always be directly opposed to their flight; but will frequently act in a line oblique to their course, and will thereby force them to deviate from the regular tract they would otherwise describe. And this is the true cause of the irregularities described in Maxim IV.

*Maxim* XII.

From the sudden trebling the quantity of the air's resistance, when the projectile moves swifter than at the rate of 1200 feet in a second, (as has been explained in Max. IX.) it follows, that whatever be the regular range of a bullet discharged with the last-mentioned velocity, that range will be but little increased, how much soever the velocity of the bullet may be still farther augmented by greater charges of powder.

*Maxim* XIII.

If the same piece of cannon be successively fired at an invariable elevation, but with various charges of powder, the greatest charge being the whole weight of the bullet in powder, and the least not less than the fifth of that weight; then, if the elevation be not less than 8° or 10°, it will be found that some of the ranges with the least charge will exceed some of those with the greatest.

*Maxim* XIV.

If two pieces of cannon, of the same bore but of different lengths, are successively fired at the same elevation, with the same charge of powder, then it will frequently happen, that some of the ranges with the shorter piece will exceed some of those with the longer.

*Maxim* XV.

In distant cannonadings, the advantages arising from long pieces and large charges of powder are but of little moment.

*Maxim* XVI.

In firing against troops with grape shot, it will be found, that charges of powder much less than those generally used are the most advantageous.

*Maxim* XVII.

The principal operation in which large charges of powder appear to be more efficacious than small ones, are the ruining of parapets, the dismounting of batteries covered by stout mortars, or battering in breach; for in all these cases, if the object be but little removed from the piece, every increase of velocity will increase the penetration of the bullet.

*Maxim* XVIII.

Whatever operations are to be performed by artillery, the least charges of powder with which they can be effected are always to be preferred.

*Maxim* XIX.

Hence, then, the proper charge of any piece of artillery, is not that allotment of powder which will communicate the greatest velocity to the bullet, (as most practitioners have hitherto maintained,) nor is it to be determined by an invariable porportion of its weight to the weight of the ball; but, on the contrary, it is such a quantity of powder as will produce the least velocity necessary for the purpose required; and instead of bearing always a fixed ratio to the weight of the bullet, it must be different according to the different business which is to be performed.

*Maxim* XX.

No field piece ought at any time to be loaded with more than $\frac{1}{6}$, or the utmost $\frac{1}{5}$ of the weight of its bullet in powder. Nor should the charge of any battering piece exceed $\frac{1}{3}$ the weight of its bullet.

*Maxim* XXI.

The depth to which the bullet penetrates in a solid substance is a much more definite criterion of its comparative velocity than the distance to which it ranges when fired at an elevation. For when the velocity of the bullet is doubled, it penetrates into an uniform substance near four times as deep, and with three times the velocity near nine times as deep;* so that, with different velocities, the penetrations vary in a much greater proportion than the velocities themselves.

*Maxim* XXII.

Hence then, in all contests about the greater or less velocity which a bullet acquires from different quantities of powder, or from different lengths of pieces, or different methods of loading, the most decisive experiment is to try the penetration of the bullet into some uniform substance, placed at a small distance from the muzzle of the piece; since that bullet which, in repeated trials, penetrates deepest, may be concluded to have been discharged with the greatest celerity.

GUNPOWDER, is a compound of nitre, sulphur, and charcoal. The chemical action which these few elementary bodies exert on each other has many times determined the fate of nations. More human beings have fallen victims to its power than at present exist upon the face of the globe, and it is now considered as the most effective agent in modern warfare.

The history of this surprising substance is clouded with much obscurity, and this we deem sufficient for not entering minutely into this branch of our subject.

Polydore Virgil and Thevet attribute the discovery of gunpowder to a monk named Constantine Anelzen, who was a chemist of some celebrity in his time. Others assert, with much probability, that it was discovered by Bartholdus Schwartz about the year 1320.

The Venetians are said to have used gunpowder during a war with the Genoese, in the year 1330. In 1346, cannon and gunpowder were used at the battle of Cressy; and about the same time at the seige of Calais.

Long before any of these periods, gunpowder is said to have been discovered by Roger Bacon. In a work written by him in 1280, he points out the composition of gunpowder; and was so much aware of its importance, as to recommend its explosive powers as the means of destroying armies.

The Chinese, and probably other nations of the East, with whom most of the arts have originated, appear to have been acquainted with a variety of these explosive compounds long before they were known to Europe. It appears almost impossible, that, in countries where nitre is found in the soil, the commonest people should have been ignorant of the action between carbon and nitre. If sulphur were not present, still the effects would be remarkable.

The preparation of gunpowder is divided into three principal departments. 1st, The choice and purification of the materials; 2d, The adjustment of the proportions, by which a maximum of explosive power may be produced; and 3d, The incorporation of the materials, which is a mechanical process not of less importance than the other departments.

In the choice of nitre, no rule is so important as the form and size of the crystals. It is necessary first to examine whether the nitre affords any foreign matter different from nitric acid and potash. It sometimes contains nitrate or muriate of lime, magnesia, and perhaps muriate of potash. First dissolve a small portion of the nitre, and filtre the solution. To a little of this, add a few drops of a solution of sulphate of silver.(*) If a bluish white precipitate falls down, which turns darker coloured by exposure to the light, then the nitre contains muriatic acid, combined with some of the bases above mentioned; namely, lime, magnesia, potash, and probably soda. Take another portion of the solution of nitre, and drop into it a solution of oxalate of ammonia. If a white precipitate falls down, it shows the presence of lime. To a third portion of the solution add a little pure ammonia, then, if any precipitate is found, the nitre contains magnesia.

In particular experiments, the tests above mentioned

(*) The sulphate of silver recommended by our author is by no means so eligible as the nitrate. The solution may contain muriate of lime, (a frequent contamination,) of course sulphate of lime would precipitate with the muriate of silver, a circumstance which could not fail to embarrass a mere manufacturer; to whom the article is chiefly interesting.

We have had frequent opportunities to examine crude salt-petre from Kentucky, and in several parcels, found sulphate of magnesia mixed with it. It is perhaps not generally known that some of the salt-petre caves in Virginia and Kentucky contain immense quantities of the latter salt. With a letter which we received in 1804, from Mr Tristram Patton, dated Second Creek, Moroe County, Virginia, we received a quantity of very pure sulphate of magnesia (epsom salt.) Mr. Patton writes, "I have a quantity of that salt, (sulphate of magnesia) in a salt-petre cave of mine, and one of my neighbours has any quantity of it, in a cave of his; we could load several waggons with it."

From the above, manufacturers will perceive that they may be led into great errors, by confining their examinanations of *crude* salt-petre exclusively to muriatic salts. The solution should be tested with nitrate of barytes; if a a precipitate ensues, it indicates the presence of sulphuric acid; separate the precipitate by filtration, and into the filtered liquor drop nitrate of silver; if a further precipitate appears, it indicates the presence of muriatic acid.

(*a*) Having thus ascertained the presence of sulphuric and nitric acids, let another portion of the solution be taken, and nitrate of barytes added as long as any precipitate appears; when that ceases, let the whole be thrown on a filter —the precipitate is sulphate of barytes.

(*b*.) Into the filtered liquor, add a solution of nitrate of silver as long as it occasions any precipitate; when that ceases, let it be separated by filtration—it will be muriate of silver. The solution now can contain no salts but the earthy and alkaline nitrates.

(*c*.) To detect the presence of lime, add a few drops of oxalate of ammonia to the filtered solution (*b*); a precipitate will appear if lime be present, provided there is no excess of nitric acid; if there is, it should previously be saturated with an alkali.

(*d*.) Magnesia and *alumina* (if the solution contains any) may be separated by adding pure ammonia or lime water to the filtered solution (*c*), provided the carbonic acid (if the solution contains any) be previously expelled by nitric acid and boiling.

Soda, if the solution contains any, may be detected by evaporating the filtered solution (*d*) to dryness, then heating the dry mass to redness with a little charcoal, to decompose the nitric acid. The remainder dissolved in muriatic acid, filtered and concentrated by evaporation, will afford cubic crystals of muriate of soda (common salt.)

If no sulphuric should be detected in the solution, the process (*a*) must be omitted.

HEMBEL, jun.

might be used to separate the foreign matter; but for general use this would be too expensive; and the only practicable method of purifying nitre, is by frequent solution, evaporation, and careful crystallization. When the crystals are transparent, clear, and well formed into distinct prisms, the nitre may be looked upon as pure. It is well to test it after every fresh crystallization, to know when it may be relied upon. If nitre should contain any alkaline sulphate, the test for this substance will be a solution of nitrate of barytes. If a precipitate is produced, add more of the same substance carefully till no more is precipitated. By this means the sulphate of the alkali becomes a nitrate, which is nitre.

The French method of purifying nitre for the manufacture of gunpowder is very simple, and has been practised with success. The nitrate or muriate of lime, or the same acids with magnesia and even common salt, are more easily soluble in cold water than the nitre itself; but particularly the earthy salts, which are most injurious. This property presents an easy means of separating them from the nitre.

The French, for this purpose, first coarsely pound the crude nitre, and put it into a copper, adding to it 20 per cent. of cold rain water. The mixture is then stirred, and allowed to remain for 6 or 7 hours. The liquid part is now drained off, and 10 per cent. more water added, which, after stirring as before, is allowed to remain one hour, and then drained off as formerly. Lastly, 5 per cent. of water is to be added, and drained off as before, leaving the whole to drain completely. By this means the deliquescent salts are carried off, and also a portion of nitre, which may afterwards be separated for common purposes.

The drained mass is now to be dissolved, by adding to it 50 per cent. of pure water at 212°. This solution is next to be placed in shallow leaden vessels in a cool place, in order to allow the nitre to crystallize, which very soon takes place. During the crystallization the solution is frequently agitated, to prevent the crystals from being too large. It is an object to have the prisms not thicker than needles, in order to promote their more speedy desiccation, previous to its being reduced to powder, for mixing with the sulphur and charcoal. As the crystals are deposited, they are removed into baskets to drain. They are ultimately placed in wicker wooden vats with double bottoms, the superior bottom being perforated, so as to allow the water to drain through into the cavity below. This nitre is deemed sufficiently pure for making gunpowder.(*)

The choice of the sulphur for making gunpowder, is easy to those who are experienced. It should be of a lively yellow colour. Its specific gravity should not be great. It should appear porous, but not shining. When a bit of it is burned upon a piece of clean glass or porcelain, it should leave no residuum.

If it does not answer these characters, it should be melted at a low heat, and skimmed from time to time. If this is not sufficient, it should be sublimed at the lowest possible heat. The sulphur which is extracted from pyrites is never sufficiently pure for this purpose. That from Italy and Sicily, which is naturally sublimed by the heat of volcanos, is the most pure.

In the choice of charcoal, it was once deemed an object even to make use of peculiar kinds of wood; but now any kind of wood properly charred is employed. The charcoal which is formed during the distillation of the pyrolignic acid is now generally preferred.

Having pointed out the proper materials, it will now be necessary to shew the manner of intimately mixing them together; for certainly we cannot with propriety call gunpowder a compound. Since that sort of contiguity essential to their readily exploding depends upon mechanical and not chemical union, it will not be wondered that gunpowder should differ so much in its qualities even with the best proportions. All the explosive chemical compounds, such as fulminating gold and silver, are uniform in their effects, because their formation is the result of chemical union.

The first business in preparing gunpowder is, to pound the materials separately and pass them through fine sieves. Then for 100 pounds of powder, weigh 75.4 nitre, 11.8 sulphur, and 12.8 charcoal. These powders are to be intimately mingled, till the mass assumes a uniform colour; that is, till no specks of yellow, white, or black appear; for the nitre, after its crystals have been dried and powdered, becomes as white as flour. Water is now to be added, and the mass agitated till it assumes the form of a stiff but kneadable paste. In this state it has been formerly kneaded or beaten in mills, called turning mills. This apparatus consists of large mortars, with pistons, or stampers of lignum vitæ. These are still worked in some manufactories, but in the works of government they are laid aside, on account of the danger arising from the heat of percussion. The machine substituted for this seems much better. It consists of a large stone in the form of a grindstone, which is made to roll upon its edge in the circumference of a circle. A vertical shaft turns in the centre of the circle. A horizontal shaft works in the centre of the stone, the height of which is equal to the radius of the circle, in the periphery of which the stone is to roll, the end of this horizontal shaft being fastened into the vertical shaft. It will be evident that, when the latter turns round, the rolling stone will go round just as a cart wheel is carried round by drawing the cart forward. The edge is a little rounded on the face, and works in a circular bed or trough, containing the paste to be worked or kneaded. The stone now goes round upon the paste, squeezing it flat. The point of contact is constantly preceded by a scraper, which goes round with the stone, and which constantly turns the paste, previously flattened, into the track of the stone, so that a new surface is always presented to its action. The size of this apparatus is sufficient to work from 50 to 60 pounds at once. It is driven by a steam engime, a water wheel, or by horses.

The paste being sufficiently worked, which cannot be too much, is now sent to the corning house, where a separate mill is used for forming the paste into corns or grains.

This process is performed in sieves with parchment bottoms, perforated with holes. These sieves are placed upon a revolving horizontal plane. The paste, in a certain state

(*) We are nevertheless satisfied, that much of the purest nitre contains some carbonate of potash mixed with it, and to that admixture we attribute much of the dampness which powder used in the navy acquires. We have elsewhere stated our conviction, founded on experiments made expressly for the purpose, that the carbonic acid cannot be expelled from its combinations but by an excess of acid and boiling. Hence, it would be proper, previously to suffering a solution of nitre to crystallize, to boil a small portion in a flask, and gradually add a few drops of pure nitric acid; if any air bubbles should rise in the liquid, it may be relied on, that the solution contains some carbonate of potash, and that gunpowder made from the nitre will attract moisture from the atmosphere—such a solution, should have pure nitric acid added to it, previously to being suffered to crystallize.

HEMBEL, jun.

of dryness, is put into the sieves, and a piece of lignum vitæ in the shape of an oblate spheroid laid upon it. A rotatory motion is given to the spheroid at the time the sieves are revolving. This forces the paste in small grains through the holes in the parchment, which is received below.

The granulated matter consists of particles of very different sizes, and some reduced to dust. These are passed through wire sieves of different sizes, to give the different sized grains in which it is sold. Those which pass through the finest sieve, and which are called dust, are made up into paste, and worked over again.

The proper grains are next to be glazed or polished. This is performed in a very expeditious manner, by putting the grains into a revolving cylinder, working like a barrel churn. This vessel should not be more than half full at once. The grains, by rubbing one against another, become smooth, and approach a spherical form.

The next operation, which has been attended with the greatest danger, is the drying. This has generally been effected by placing the powder upon shelves on three sides of a small room, on the other side of which is an iron stove; the fire being fed from the back of the wall. When we recollect that the stove itself is frequently hot enough to explode gunpowder, it is surprising that more safe methods have not been adopted. Steam appears to be the most proper agent to be employed, not only for the sake of avoiding danger, but it is better calculated to dry the powder more effectually, without any fear of the powder being injured in its quality. It is recommended that powder be not dried too quick, or with too great a heat, for fear of volatilizing the sulphur. All these precautions are unnecessary with steam, as sulphur only evaporates at 220°; and steam would not raise it so high as 212° without pressure. The shelves on which the powder is laid to dry might be made of cast iron, and hollow. The inner cavity might have a sloping bottom, so that when the steam came into it from a boiler below, the water, after condensation, might run back into the boiler. There would, of course, be no waste of water, which should be rain water. The steam might be formed from a fire, at a sufficient distance to avoid the risk of any accident. This method would not be less desirable in an economical point of view. The powder should be kept on the stove till the time of barrelling, for which the finest dry weather is always preferred.

A very great improvement has lately been made in preserving gunpowder, by using barrels of copper instead of wood. These barrels are first made water and air tight; and then the lid screws on so as to exclude completely all communication with the atmosphere. This has been of the greatest importance, particularly in the navy.

Having given the direct practical method of forming gunpowder, we shall now give some account of its chemical properties, from which alone we can get at any true theory of its effects.

The ingenious Mr Robins appears to have been the first who has examined gunpowder scientifically. He very properly conceived, that its power consisted in the evolution of an abundance of some elastic fluid liberated in an instant, and strongly increased in its force by the heat attendant on the explosion. Having convinced himself that a permanently elastic fluid was generated during the explosion of gunpowder, his next business was to ascertain what proportion this bore to the whole weight of the powder. For this purpose, he exhausted the receiver of an air-pump, the capacity of which was equal to 520 cubic inches. In this he suspended a hot iron capable of firing gunpowder, and a mercurial gauge to ascertain the force of the air generated. On letting 27 grains of powder fall on the iron, the mercury indicated an increase of elastic fluid, which raised it two inches; and upon repeating the experiment, he found this result confirmed. The barometer at this time was 30 inches, so that the quantity of elastic fluid generated was equal to $\frac{1}{15}$ of an atmosphere. He guesses the temperature of the receiver to be such as to increase the volume $\frac{1}{5}$th of the whole. He then calculates the weight of this volume of gas, allowing its specific gravity to be the same with common air, to weigh 131 grains, for every ounce of 437.5 grains of gunpowder, which is $\frac{131}{437}$, or nearly $\frac{3}{10}$ of the whole.

From determining the specific gravity of gunpowder, he found that the bulk of the powder to the volume of gas generated, was as 1 to 244.

He next supposes that the heat generated by the explosion of the powder, would have the same effect in expanding the generated elastic fluid which a red heat would produce. He then ascertained, by an experiment, that air was increased in volume by a red heat 4.1 times nearly. This would make the volume of the powder to that of generated air as 1 to 1000 nearly. The force which would arise from such an increase of volume, Mr Robins finds adequate to the effect of the powder in practice, and in a very ample manner agreed with his theory.

We have to lament that these experiments were not made with more precision. The gases generated were considered by Mr Robins as common air, the specific gravity of which is 1. These gases, however, being a mixture of carbonic acid, carbonic oxide, and azotic gases, should have been taken at a mean not less than 1.25. There is also some uncertainty about the allowance made for the heat of the receiver; and the volume was not increased by that circumstance so much as $\frac{1}{5}$th of the whole, which he supposes to be the case. The very little which was known of gaseous chemistry at the time Mr Robins made his experiments, does not admit of our wondering that no more was established by his labours. The constituents of nitre were then little known; and therefore the nature of the gases resulting from the decomposition of gunpowder could not be ascertained. He was satisfied with calling the gaseous product air, and supposed it to have only the properties of common air. In order to apply the chemical facts at present known to explain the nature of gunpowder, we shall compare the proportions of the ingredients used by different manufacturers with those proportions which theory could point out, in order to produce a *maximum* effect.

An intelligent account of making gunpowder has been given by Mr Coleman, of the royal gunpowder mills at Waltham Abbey. (*Phil. Mag.* vol. ix.) In some observations at the end of the paper, Mr. Coleman has taken a very proper view of the theory of gunpowder, by giving some calculations relative to the resulting products. He has taken into the account the water, which he rates at 4 per cent. It has not been ascertained, that water undergoes any change in the decomposition of gunpowder; nor, indeed, is it very probable that any such effect takes place. He has also given too little oxygen for sulphurous acid. He states it to be 30 per cent. when it is actually 50. It appears from experiments made in the firing of gunpowder, that very little of the sulphur enters into combination with the oxygen, and we believe not after the carbon is kindled. The residuum is always very near a complete sulphuret of potash; and the quantity of sulphur used in the composition is seldom more than is just sufficient to form the sulphuret. This is rendered highly probable, from the fact of gunpowder possessing the same strength with very different proportions of sulphur. Indeed, M. Chaptal has made very good gunpowder without sulphur. It is however different, in a mechanical point of view, and on that account would not answer in practice. It is therefore highly probable, that the sulphur does not form sulphurous acid when the explosion takes place, since oxygen seems to unite with the carbon alone. The potash, when deserted by oxygen and the nitrogen, assumes the form of a fine dust of powder, and the sulphur the form of vapour. These combine, forming a sulphuret of potash, which appears in white fumes, and adheres to surrounding bodies. The moment this white efflorescence is touched with the tongue, the exact taste of sulphuret of potash is perceived. If the carbon were very defective in quantity, and the sulphur in the usual proportion, some sulphurous acid would doubtless be formed, and the smell of it would be very perceptible in the fumes resulting from its decomposition; but no smell of this kind is perceived in the explosion of ordinary gunpowder.

The following Table contains some of the proportions used by different manufacturers in this and other countries.

| Varieties of Gunpowder. | Nitre. | Charcoal | Sulphur |
|---|---|---|---|
| Mr Coleman, of the Royal Mills at Waltham Abbey, . . | 75 | 15 | 10 |
| General use in France, . . | 76 | 12 | 12 |
| War powder of France, . . | 75 | 12.5 | 12.5 |
| Result of experiments by M. Chaptal, . . . . . . | 77 | 14 | 9 |
| Used in China, . . . . . | 75.7 | 14.4 | 9.9 |
| Result of Mr Napier's method of approximating the true proportions, . . . . . . | 80 | 15 | 5 |
| Average, . . . . | 76.45 | 13.81 | 9.73 |

Doubtless all these varieties are very good powder, which would not have been the case, had the charcoal been as uncertain in its proportions as the sulphur.

It will be admitted on all hands, that the best gunpowder must result from such materials as explode the quickest, leaving the least possible residuum, and affording the greatest possible volume of elastic fluid. Now, if sulphur did, by its combination with oxygen, form an elastic fluid, the resulting gas, which is sulphurous acid, is nearly 1.5 times heavier than carbonic acid, and therefore contributes less force in a given weight. It will be found, when nitre is deflagrated with charcoal, that carbonic oxide is formed as well as carbonic acid, which contributes more elastic force than the same weight of carbonic acid.

There is one good reason to be given for the use of the sulphur, although it does not contribute to the production of any elastic fluid. The carbonic acid which is generated would doubtless combine with the potash, if it were not for the presence of the sulphur; and thus so much elastic fluid would be lost. That this is the case, we know from the fact, that carbonate of potash is always formed when nitre is decomposed by charcoal alone. This would be the case to a certain extent with gunpowder made without sulphur; some carbonate of potash would be formed.

It will appear, from these facts and observations, that the propositions for gunpowder will be those in which the carbon will just consume the oxygen of the nitre, and the sulphur as much as will exactly saturate the potash. This will be effected by an atom each of nitre and sulphur, and three atoms of carbon, or nitre 95.5; charcoal 16.2; and sulphur 15. These will give in the 100 nitre 75.4; of charcoal 11.8; and sulphur 12.8. These proportions agree with the best in practice. The bodies which result from the decompositions of this compound, will be in 126.7 parts, 60 of sulphuret potash; 40 8 of carbonic acid; 12.9 of carbonic oxide; and 13 of azot.

The three latter are elastic fluids, equal to 66.7 out of 126.7, or $\frac{4}{21}$ of the whole nearly. Mr Robins made the gaseous product $\frac{3}{10}$ of the whole. This last number, when the specific gravity of the gas is taken right, will differ very little from our calculation.

In the 66.7 by weight, (suppose grains,) we have

| | | |
|---|---|---|
| Carbonic acid . . . . | 10.8 = 87 | cubic inches. |
| Carbonic oxide . . . | 12.9 = 42 | |
| Azot . . . . . . . . | 13. = 40.6 | |
| | Total 169.6 | |

Now Mr Robins found that 27 grains of powder generated as much air as made $\frac{1}{15}$ of an atmosphere in a space equal to 520 cubic inches. This, at the pressure of the atmosphere, which was at the time equal to 30 inches, would make 34.6 cubic inches. The increased temperature which the receiver got by the explosion might reduce this to 30 or 31. We find from our calculation that 126.7 of gunpowder generates 169.6 cubic inches of gas. Then as 126.7 : 27 : : 169.6 : 35.7 cubic inches, which is only three cubic inches different from Mr Robins' experiment. This might arise from his powder not consisting of proper proportions.

In the present improved state of chemical science, when the nature of the bodies constituting gunpowder are so well understood, as well as the compounds resulting from their action on each other, the proportions above given may be taken as the best for practice. The charcoal should, in particular, not be less in proportion to the nitre, as the smallest portion less than a whole atom would be the same as to leave out the whole atom, in which case there would be no carbonic oxide formed. If, for instance, instead of the proportions 95.5 nitre, 16.2 charcoal, and 15 sulphur, the carbon was 16, then there would be 4.2 of carbon left in the resid[illegible] no carbonic oxide would be formed; since bodies cannot unite but in definite proportions.

The reason why carbonic oxide is formed during the decomposition of nitre by charcoal will be obvious from nitric acid having five atoms of oxygen. Four of these unite with two of carbon to form two atoms of carbonic acid, while the odd atom of oxygen is compelled to take another atom of carbon to form carbonic oxide. The writer of this article found the presence of the latter substance a fatal objection to getting pure carbonic acid by deflagrating nitre with charcoal.

The goodness of gunpowder is known to those experienced in it by its appearance. It should not be strictly black, but of azure grey inclining to red. The grains should appear uniform, both to the eye and to the touch. If some rub to powder sooner than others, it shows that the mass is not well mixed.

When it is fired on clean paper, or on a clean board, it should not soil it, or leave black spots. The smoke arising from it will form a circle or ring, more or less perfect as the explosion is more or less rapid, and is a good test of its strength.

The best and most certain test of the strength of gunpowder is the *eprouvette*. This is a machine in which the powder acts against a weight, in order to raise it to a given height. The powder in these machines, however, acts by a sudden impulse, and not as it acts in a gun, which is by gradual pressure during the whole time the charge is passing through the barrel. Hence the common powder powers are very imperfect, and have been long deemed insufficient. The French method of trying powder is more to be depended upon, but it is more tedious, and takes up too much time for practice.

Each of the magazines for powder have a small mortar, exactly of the same size, and capable of containing a ball of $7\frac{1}{2}$ inches in diameter. The mortar is elevated to an angle of 45°; and when the powder is of the required strength, 3 ounces of it is capable of projecting the ball of the above size 55 French fathoms.

Mr Robins proposed a much more certain apparatus for trying the strength of powder, which has since been executed and reduced to practice by Dr Hutton. It is founded on the principle, that the momentum of the gun and the charge must be equal, or that the force of the powder, which is equally exerted upon both, will generate velocities in each, which will be inversely as their quantities of matter. Thus, if the weight of the charge were 1, that of the gun being 100, then their velocities will be reciprocally as these numbers. For this purpose, Dr Hutton's machine consists of a brass cannon of about one inch bore.* Plate CCLXXXIV. Fig. 10, 11. It is suspended in such a way, that the arch of its recoil can be easily ascertained. The gun is generally charged with two ounces of powder. The arch of recoil gives the velocity with which it is propelled, and hence the force of a given quantity of powder. No wadding is used in this method, the powder being merely collected into as compact a mass as possible. In these experiments, it should always be ascertained whether the whole of the powder be fired.

The strength of powder might be very conveniently and correctly ascertained, by firing a bullet into some uniform medium, such as sand or clay. The medium may first be tried, by letting a ball fall from a given height into it, and observing the depth to which it has penetrated. Since these depths are the spaces through which the ball has passed to lose motion, which is supposed to have been uniformly retarded, they will therefore be as the squares of their velocities. Hence, when the space has been determined by the falling body, of which the velocity was known, the first velocity of the projected body may be determined, the space through which it has penetrated being known.

Since the force of gunpowder is exerted in a manner similar to the action of condensed air, which is analogous to the action of a spring, there appears nothing more necessary to be known than the volume of elastic fluid set free, and its temperature, to know what is its velocity of expansion when no matter has to be moved.

Mr Robins first ascertained the volume of air formed by a given quantity of gunpowder, and then supposed that this elastic fluid was exposed to a heat equal to redness, by the explosion of gunpowder. He also found, by experiment, how much the volume of a given bulk of air was increased by a red heat. The first production of air gave him a force of about 244 atmospheres, or that the original volume of gunpowder was multiplied by that number. The red heat he found would multiply this volume by about 4.1. This gave about 1000 times for the increase of volume. The force of its first action would therefore equal so many atmospheres, or $1000 \times 15$ pounds upon a square inch. When this force begins to move, it decreases with the dilatation, and exactly in the same ratio. Mr Robins not only ascertained the velocity given to the bullet by a given weight of powder, but he fired the powder alone, which having no weight to move, would expand itself with the greatest velocity. He found that, under these circumstances, the velocity of expansion was 7000 feet in one second.

In these experiments, the charge, at a small distance, was fired at a piece of wood, constituting the bob of a pendulum. Plate CCLXXXIV. Fig. 12. This pendulum had a ribbon attached to it, which was slightly held between two surfaces, so that, when the pendulum vibrated, the length of the ribbon drawn out measured the cord of the arch of vibration, by which the velocity of the striking body was known. See the *Description of Plates*.

Count Rumford has advanced some new notions respecting gunpowder, deeming the reasons for its power given by Mr Robins insufficient, viz. the gases and the heat. He attributes the power of the powder to the vapour of the water it contains, and supposes the heat to be the result of friction. His views of the subject have not been countenanced by other philosophers, as they appear to be contrary to experience. Mr Robins, and more recently Mr Coleman, found that powder was the strongest in its most dry state, if none of the materials were injured, and that it became weakened by the slightest quantity of moisture.

Notwithstanding all the caution used in purifying the nitre, all powder has a great tendency to absorb moisture from the atmosphere. This may go on to a considerable extent, without any permanent injury to the powder, its power being restored by drying. If, however, the water absorbed be sufficient to effect a solution of nitre, the latter afterwards crystallizes, and appears like hoar-frost upon the grains of the powder. This is called the starting of the salt-petre, when the powder is not capable of being restored to its original strength by drying; for the nitre is, to a certain extent, detached from the other two ingredients. Powder is sometimes so much injured by dampness as to be of no value, except in so far as the nitre can be recovered from it by solution. (c. s.)

GUNPOWDER Plot. This conspiracy, one of the most iniquitous and daring treasons recorded in history, was the memorable offspring of religious bigotry. It had its origin in the disappointed zeal of the Catholics, and has contributed more than any thing to fix upon themselves that very intolerance, of which they have given so many and such dreadful examples.

After the death of Mary, who was regarded as a martyr to their cause, they rested their last hope on the favour and protection of her son. Of these they pretended to have received the most unequivocal assurance; and mere toleration was among the lowest of their anticipations. James quickly undeceived them; and though certainly less hostile to their religion than jealous of the papal supremacy, he shewed a confirmed resolution of at all times enforcing against them the enactments of the two preceding reigns. Their surprise and rage at this conduct were excessive. They saw nothing before them but submission or revenge; and they chose their part. Robert Catesby, a gentleman of ancient family, and whose character in other respects suited little with the desperation of a zealot, formed the terrible scheme of at once avenging and retrieving their lost ascendancy. He imparted his thoughts to a few zealous Catholics, among whom were Piercy, Rookwood, and Sir Everard Digby. A meeting was held, to consult what measures would best accomplish their purpose. Piercy, in the true spirit of fanaticism, proposed to assassinate the king, and to be himself the instrument; but Catesby, with deeper purpose, laid before them a wider plan of vengeance. He represented to them the inefficacy and the danger of striking a single victim, which would but mark out themselves for a more dreadful atonement. He shewed them that the whole of their enemies might be struck at once,

* See the Description of this Plate at the end of the volume.

by running a mine below the House of Parliament, and when all should be assembled, at the opening of the session, blowing them up in one common ruin, and consigning them, as he chose to express himself, "from flames above to flames below." The scheme was received with enthusiasm. A few more Catholics were taken into the plot; and, with the others, had their consciences absolved by the Jesuits Garnet and Tesmond. Among these was the famous Guy Fawkes, who had been sent for from Flanders, and was well fitted, by his zeal and intrepidity, to take a prominent share in this extraordinary enterprize.

The plot being now fully concerted, a house adjoining the House of Parliament was hired in Piercy's name, and the operation commenced towards the end of the year 1604. Nothing could exceed the industry with which it was forwarded. A store of provisions was taken in, to prevent the necessity of interruption; and the conspirators came armed to the work, determined to succeed, or perish in the attempt.

Between the houses was a partition wall, three yards thick. This, after much labour, they succeeded in piercing; but just as the work opened to the other side, they were alarmed by an unaccountable noise from below. Fawkes, who passed himself for Piercy's valet, went out to enquire into the cause, and learned, to their inexpressible satisfaction, that the sounds they had heard proceeded from a coal vault under the House of Lords, where coals were at that moment selling off, and that the vault itself would be let after the sale. The conspirators seized with eagerness the opportunity, bought up the remainder of the coals, and hired the place. Thirty-six barrels of gunpowder were procured from Holland, conveyed into the vault, concealed under coals and faggots, and the doors boldly thrown open, as if to challenge inspection.

Matters being thus far in preparation, there remained but one obstacle to the completion of the enterprize. The Duke of York and the Princess Elizabeth, on account of their youth, would be absent from Parliament, and escape destruction. It was resolved, therefore, that when the explosion should have done its work, Piercy, who, as a gentleman pensioner, had access to the Palace, should carry off or assassinate the Duke, while Sir E. Digby, having assembled his friends on pretence of a hunting match, was to seize the princess, then at Lord Harrington's house in Warwickshire, and proclaim her queen.

Every thing was now arranged for the dreadful issue. The day approached (the 5th of November) appointed for the meeting of parliament. The conspirators looked forward to a certain triumph, when, fortunately for the country and for Protestantism, the indiscretion of a Catholic laid open the treason.

Ten days before the sitting of parliament, Lord Monteagle, a Catholic, son of Lord Morely, received from a person unknown the following letter. It had been put into the hand of his servant, with express injunctions to be delivered only to himself. "My Lord, out of the love I bear to some of your friends, I have a care of your preservation. Therefore I would advise you, as you tender your life, to devise some excuse to shift off your attendance at this parliament. For God and man have concurred to punish the wickedness of this time. And think not slightly of this advertisement; but retire yourself into your country, where you may expect the event in safety. For though there be no appearance of any stir, yet I say they will receive a terrible blow this parliament, and yet they shall not see who hurts them. This council is not to be contemned, becsuse it may do you good, and can do you no harm. For the danger is past as soon as you have burned the letter, and I hope God will give you grace to make good use of it." Neither Monteagle nor Salisbury, to whom he carried the letter, was inclined to regard it seriously. James was the first to penetrate its meaning. The words quoted by Salisbury, to prove to him the folly or insanity of its author, viz. "the danger is past *as soon* as you have burnt the letter," James interpreted to signify, not that the danger would be past when the letter was burnt, but that it would pass in a space of time as short as the burning of the letter might occupy. This, compared with the preceding threat of a "terrible blow," the authors of which would be concealed, suggested to the king the agency of gunpowder. It was determined, therefore, to have an inspection of all the rooms and vaults below the houses of parliament. This duty was performed the day before the meeting by the Lord Chamberlain, who, besides noticing the prodigious pile of fuel, did not fail to observe also the dark, intrepid, and suspicious countenance of Fawkes, who, still passing himself for Piercy's servant, loitered about the cellar. This being reported to the council, a more particular search was deemed advisable. Accordingly, Sir Thomas Knevet, justice of peace for Westminster, went with proper attendants at midnight, and seized Fawkes, just as he had completed his preparations, and was leaving the vault. He was dressed in a cloak and boots, and held in his hand a dark lantern. Matches being found upon him, and the powder discovered under the fuel, the guilt became apparent, and he no longer sought to conceal it. He broke out in a tone of defiance and contempt, expressing, in the strongest manner, his extreme regret that so many heretics had escaped his vengeance, and declaring that he could attribute only to the devil the frustration of so good a work. He met the council with the same scornful intrepidity, and obstinately refused giving any account of his accomplices; but, after two days solitary confinement in the Tower, and the rack being just set before him, his courage was shaken, and he made a full disclosure of the treason. Upon the first notice that Fawkes was arrested, Catesby, Piercy, and Winter, fled hastily into Warwickshire, where they joined the party of Sir E. Digby. Sir Everard, having failed in his attempt to seize the Princess, was already pressed, and almost beset by the sheriffs. After being driven for some time from place to place before their enemies, they made a resolute stand at the house of Holback, in Staffordshire; but here part of their powder having accidentally exploded, they were thrown into the utmost confusion, the gates were flung open, and the armed multitude rushed in upon them from all sides: Catesby and Piercy, fighting back to back, fell by the same shot; Winter, Digby, and Rookwood, were taken alive, and, with the Jesuits Garnet and Oldcorne, suffered by the executioner. More were afterwards convicted; and some owed their lives to the clemency of James.

Stourton and Mordaunt, two Catholic lords, having been absent from parliament, were suspected of connivance, and fined, the former in 4000*l.*, and the latter in 10,000*l.* The Earl of Northumberland fell under the same suspicion. It was discovered, that, as captain of the band of Gentlemen pensioners, he had excused his cousin Piercy, upon his admission into that corps, from taking the customary oaths. He was stripped of his employment, imprisoned during the king's pleasure, and fined in 30,000*l.*

Such was the issue of this memorable treason,—a treason scarcely more memorable for the desperate zeal and devoted bigotry of its conductors, than for the magnitude of its purpose, and the deep atrocity of its guilt. It has not the excuse of precipitation or passion. Though undertaken perhaps in the freshness of imagined injury, it was meditated for years, and with increasing zeal and approbation. Neither was it the offspring of ignorance and depravity; its leaders were the most esteemed and most enlightened of their religion. Hence may be traced in the minds of Protestants, a jealousy and a prejudice, which, even in these times, yield, with much reluctance, to the better views and more tolerant spirit of enlightened Christianity. GUNSHOT Wounds. See Surgery.

GUNTER'S Line. See Arithmetic, and Logarithmic Scales.

GURNIGHEL, is the name of a mountain in the canton of Bern, and situated to the north of the chain of the Stockhorn, on the confines of the country of Schwartzenbourg, and six leagues to the south of Bern. It is principally remarkable for its baths of sulphurous waters, which are situated on the north-west side of the mountain, at the side of a fine wood of firs, and which are accessible to carriages, notwithstanding the great height of their situation. One of the springs, called Stockwasser, issues from the ground, about a quarter of a league from the baths. Its temperature is $+ 6°$ of Reaumur. Fourteen ounces of this water contains, according to M. Morell of Bern, carbonic acid gas, mixed

| | |
|---|---|
| With hepatic gas | $3\frac{1}{2}$ cubic inches. |
| Carbonate of magnesia | $2\frac{3}{4}$ grains. |
| Lime | $1\frac{1}{2}$ grain. |
| Sulphate of lime | $8\frac{1}{8}$ grains. |
| Sulphate of magnesia | $\frac{3}{24}$ grain. |
| Sulphate of soda | $\frac{3}{29}$ grain. |
| Iron | $\frac{3}{40}$ grain. |

A second spring, which is called Schwartzbrunlein, has a strong sulphurous odour. It is at first very limpid, but is rapidly decomposed by the air, and becomes as white as milk. It is more powerful than the other spring, and great quantities of it are sent in bottles hermetically sealed to Bern, at the price of about 11 sous. The lodging-house is commodious, though by no means sumptuous. The expence of board is about 6 or 7 French livres per day. From the house there is a fine view over the whole of the canton which is comprehended between the Jura and mountains of Emmenthal, and also of the town and lake of Neufchatel. See Ebel's *Manuel*, &c.

GUSTAVUS Adolphus, commonly called the Great, King of Sweden, was born at Stockholm in the year 1594. He was educated with particular care, and instructed in all the learning and accomplishments which are calculated to form a statesman and a hero. His genius was great, his memory prodigious; and he discovered an uncommon docility and desire of acquiring knowledge. In the year 1611, he ascended the throne of Sweden, being then only 18; but the vigour of his character, and his various acquirements, compensated the disadvantage of his youth: and the choice which he made of his ministers and counsellors, evinced his ability to conduct the government of the kingdom, at the head of which he was placed.

Soon after his accession, he was involved in war with the Danes, the Russians, and the Poles, from which he extricated himself with great valour and prudence; having increased his hereditary dominions by the acquisition of Livonia, which he wrested from the two last mentioned powers. In the year 1630, he was invited by the German Protestants to join the league against the Emperor; and by his powerful assistance, and the good conduct of his arms, he greatly contributed to the ultimate success of their cause. On his departure from Sweden, he called together the states of the kingdom; and having caused them to do homage to his daughter Christina, then only four years old, he took leave of them in a discourse, in which he explained, at length, the motives that prompted the enterprize he was about to undertake.

In the month of June 1630, Gustavus landed on the coast of Pomerania, with an army of 15,000 men. At first, his operations were greatly impeded by the jealousy and discord that reigned among the Protestant Princes of Germany, who seemed to be actuated rather by their own selfish interests, than by any enlarged view to the general good. However, he soon expelled the imperial troops from Pomerania, and forced the Elector of Brandenburgh to embrace his true interest, by affording every facility to the enterprize of the Swedes. The King then resolved to hasten to the relief of Magdeburg, which was besieged by the imperial generalissimo Count Tilly; but his views were frustrated by the strange conduct of the Elector of Saxony, who refused to permit him to pass the Elbe; and he had the mortification to receive intelligence of the fall of that important fortress, accompanied with circumstances of atrocity, which have stamped indelible infamy on the name of Tilly. The haughty and cruel conduct of the imperial commander soon brought the Elector of Saxony to a sense of his situation and true interest; and having joined his forces to those of the King of Sweden, they encountered the enemy under Tilly, at Breitenstein, near Leipsic, on the 7th of September 1631. A battle ensued, which terminated in the total discomfiture and rout of the Imperialists. The victorious King now advanced along the Maine, as far as the Rhine; forced the city of Mentz to capitulate; drove the Spaniards out of Germany, and freed the Palatinate. He then turned his arms against Bavaria; and Tilly, who endeavoured to dispute with him the passage of the Lech, was again defeated, and perished in the attempt.

His loss was supplied by Wallenstein, who was now placed at the head of the imperial armies; and commenced his operations by driving the Saxons out of Bohemia. Meanwhile Gustavus, pursuing his victorious career, had advanced into the heart of Bavaria, and made himself master of Munich. As he approached the Austrian dominions, Wallenstein hastened to their relief, and compelled the king to retire. The two armies met at Nuremberg, and formed entrenched camps opposite to each other, where they remained inactive during two months. It was the policy of Wallenstein to avoid a battle, in hopes that the Swedish army would be weakened by famine and disease. At length the latter made a vigorous attempt to storm the entrenchments of the Imperialists; but, for the first time since their landing in Germany, they received a severe check; and, after a fruitless exhibition of valour, Gustavus found himself compelled to retire, the whole of the neighbouring country being completely exhausted of provisions. He was followed into Saxony by Wallenstein; and the two armies again met at the village of Lutzen, near Weissenfels. Here a sanguinary battle took place on the 6th of November 1632, which was fought with great skill, and with the most obstinate courage, on both sides. The intrepidity and discipline of the Swedes, however, at length prevailed, and the Imperialists were driven from the field. But the victory was dearly purchased. Besides a great loss of men, the conquerors had to lament the death of their adored king, who was killed by a musket shot, while gallantly leading on his cavalry to a charge against the broken ranks of the enemy. After the battle, his body was found lying near a large stone, which, in commemoration of this circumstance, was called the *Schwedenstein*, (Swede stone,) and which still indicates the spot where the great vindicator of the religious liberties of Germany terminated his victorious career. Thus fell Gustavus Adolphus, in the thirty-eighth year of his age. The ball which inflicted the mortal wound entered his back, and passed through his body. This circumstance, among others, excited a suspicion of treachery; and the Duke of Saxe-Lawenburgh, one of his generals, who immediately afterwards left the Swedish service, has been expressly pointed out by some historians as the assassin of his royal commander. There is, however, no positive evidence of his guilt, and the fact is to this day doubtful.

Gustavus left behind him the character of a good Christian, a great king, a prudent statesman, and a consummate general. Amidst the operations of war, he did not neglect the cultivation of the sciences. He enriched the university of Upsal, established a royal academy at Abo, and founded an university at Dorp in Livonia. Before his time, there were no regular troops in Sweden; but he formed and executed the project of having 80,000 men, constantly well armed, clothed, and disciplined. He was acknowledged to be the greatest captain of his time, and the bravest soldier in his army; and the military art is indebted to his genius for several great improvements. He formed his cavalry into smaller subdivisions, which enabled them to move with greater ease and rapidity; his order of battle was composed of two lines, (instead of one, according to the usual practice,) in order that the second might advance, in the event of the first being broken; and he was the first who demonstrated, in modern times, the importance of a well-disciplined infantry in the field. His own army was a perfect pattern of good order. The morals of his soldiers were to him an object of equal attention with their courage and military discipline. Temperance was commanded as a duty by the Swedish laws of war; excesses of every kind were severely punished; and every regiment mustered, morning and evening, around its chaplain, to perform their devotions in the open air; the king himself being always present upon those occasions. He endured all the hardships and privations of war with the meanest of his army; and never spared his person in the hour of danger.

He not only extended his dominions, and raised the reputation of Sweden abroad, but also turned his attention to the constitution of his country, which he would probably have improved had he lived to return into his own kingdom. By his regulations, however, the succession to the crown, which had been previously limited to the male line, devolved upon his daughter Christina, who was only six years old at the period of her father's death. See Harte's *Life of Gustavus Adolphus*; Schiller's *History of the Thirty Years War*; and the *Gen. Biog. Dict.* (z)

GUTTA SERENA. See SURGERY.

GUTTEMBERG. See PRINTING.

GUZERAT, or GUJRAT, a large province in Hindostan, situated principally between the 21st and 24th degrees of North Latitude, is about 320 miles in length, and 180 at its average breadth. Its south-west portion approaches the form of a peninsula, lying between the gulfs of Cutch and Cambay; but it stretches far inland towards the north-east, having the province of Cutch on the west, Malwah and Khandesh on the east, Aurungabad on the south, and Agimere or Ajimeer on the north. It was one of the 11 soubahs,* into which Akbar divided Hindostan; and is understood to have, at that time, extended southward as far as Damaun. It contained nine circars, namely, Guzerat proper or Ahmedabad; Putten; Nadowt; Behrodeh, or Baroda; Behroatch, or Baroche; Chumpaneer; Kodehra; and Surat. These were subdivided into 198 pergunnas, of which thirteen contained sea ports. The whole Soubah furnished 67,375 cavalry, and 8900 infantry; and, in the reign of Aurungzebe, the amount of its revenue was equivalent to 1,800,000*l.* sterling.

Guzerat was subdued in 975 by the Afghans or Patans, a hardy race, from the mountainous regions between Persia and Hindostan, who established the extensive empire of Ghizni, and maintained their authority till the end of the thirteenth century, when the Moguls commenced their ravages. In the fifteenth century, it was governed as an independent kingdom, by a dynasty of Rajpoot princes, who had adopted the Mahommedan religion, and removed the seat of government from the ancient capital Nehrwallah to Ahmedabad. In 1572, it was reduced by the emperor Akbar; and was, at that period, in a flourishing state as a maritime and commercial country. In the beginning of the 18th century, after the death of Aurungzebe, many of the more distant provinces renounced their allegiance to the Mogul emperor; and the governor of Ahmedabad and Cambay, following these examples, assumed the sovereignty of that part of Guzerat. About the middle of the 18th century, it was conquered by the Mahrattas under Ragonauth Row; and its nabob Mohman Khan, took refuge in Cambay, where he held a small territory, subject to the payment of an annual tribute to the Mahrattas. The capital was taken from the Mahrattas by general Goddard in 1779; but for political reasons was ceded to Futty Singh, a Hindoo chieftain, and at the end of the war in 1783 was restored to the Mahratta government. The more civilized and cultivated districts are at present possessed by the East India Company, the Guicowar and the Peishwa. The territories of the Company comprehend a considerable extent of country on both sides of the Gulf of Cambay; and include the populous cities of Surat, Baroche, Cambay, and Gogo. The sea-coast, from the Gulf of Cambay to the river Indus, is occupied by different independent chiefs, who are generally addicted to piracy, and are kept only in awe by the naval superiority of the British. The northern, western, and even central quarters of the province, have been but recently explored, and are overrun, or rather occupied by numerous tribes of armed banditti, who are thieves not so much by profession as by nation.

The province of Guzerat, in its general aspect, is flat and unvaried. In many places, not the smallest stone is to be seen; and there is scarcely a rising ground in the whole district to the west of Powagur, the name of the mountain by which it is separated from the interior of Hindostan. It is more hilly towards the eastern frontier, and much covered with jungle. Much of the more level tracts is either an arid sandy country, or a saline swamp of a singular description, which, even when dried up, remains in a great measure sterile and unproductive. In those places, also where the surface is apparently smooth to the eye, it is much intersected by ravines, of considerable extent and depth, which in the rainy season are filled with rapid torrents, and cannot be crossed without the assistance of rafts or boats. It is, nevertheless, especially in its western districts, full of the richest prospects, and is inferior to no part of Hindostan in beauty or fertility.

The only mountain in the province is that of Powagur, a steep and rocky height, resembling the Table Land of the Cape of Good Hope, but apparently more lofty. On its summit is a strong hold, deemed impregnable, and supposed to be the Tiagura of Ptolemy.

Guzerat is watered by several large rivers, of which the most considerable are the Myhi, which takes its rise near

* Akbar divided Hindostan into eleven soubahs, or grand divisions; each of these into smaller provinces called circars; and each of these again into districts or pergunnas. A twelfth was afterwards added, formed of countries west of the Indus.

Amjerrah, the capital of Rajode, and, running in a south-west direction, falls into the bottom of the Gulf of Cambay; the Nerbudda, supposed to be the Narmada of the Greeks, which rises in the mountain of Pindara, near the north-east corner of Berar, and proceeding westwards about 640 miles, terminates its course on the east coast of the Gulf of Cambay; and the Taptee, which descends from the mountains of Burhanpour, and after a course of above 320 miles, nearly parallel to that of the Nerbudda, falls into the sea below Surat. These larger rivers are ordinarily extremely gentle and pellucid; but begin to swell some time before the rain falls in the low countries; and then become furiously rapid, frequently sweeping away whole villages, with the inhabitants and their cattle. In the rainy season, the mountain torrents swell the smallest streams in a wonderful manner, so as to make them rise in a few hours 20 or 30 feet above their usual level. In the dry season, nevertheless, a great scarcity of water is experienced in many places, especially in the sandy soil to the north of the Myhi river, where the periodical rains are speedily absorbed, and wells must be dug to the depth of 80 and 100 feet.

The rainy season sets in with the south-west monsoon before the middle of June, accompanied with tempestuous weather, and continues with more or less violence about four months. The greatest quantity of rain always falls in July; yet, in the province of Guzerat, there is not so much rain during the wet season as there is at Bombay, and the southern part of the Malabar coast. In December, January, and February, the mornings and evenings are cold and sharp, and sometimes ice has been seen at Surat in the month of January. At this period the thermometer is frequently under 60° at sun-rise, and seldom exceeds 70° at noon; and the weather throughout the whole day is temperate and agreeable. But, in the succeeding months, during the prevalence of the hot winds, though the morning may be tolerably cool, the thermometer gradually rises from 70° to 100°; and in the plains near Cambay, has been observed at 116° in the soldier's tents. During the hot and dry months, the surface of the country is covered with sand or dust; and, in the rainy season, becomes a thick mire, and often a sheet of water.

The soil is generally sandy or marshy; but, in the cultivated districts, is a reddish light earth, or a rich black mould, both of which are highly fertile and productive. Except for the richer crops, manure is seldom required; and the dung of the cow-house is then the principal substance employed. In some of the pergunnas, particularly in Brodera and Jambooseer, the fields are inclosed, and the country enriched with plantations of mango, tamarind, and banian trees. The different kinds of grain are generally sown in June, and reaped in September. Wheat and barley are raised in many districts. Rice is a principal article of cultivation; and a great variety of Indian grains is every where produced. Of these may be mentioned the juarree, or cush-cush, (*holcus sorchum* of Linnæus,) a fine large plant, resembling maize or guinea corn, growing to the height of eight or ten feet, each stalk bearing several ears, the largest of which will frequently contain 2000 seeds; bahjeree, (*holcus spicatus* of Linnæus,) resembling the last, but inferior in size, and only used by the poorer classes; codra, chena, buntee, bowtah, growing to the height of two or three feet, and yielding grain of a nutritious quality; various pulses, especially tuar, (*cytisus cajan*) resembling split peas; mutt and gram, (*dolichos biflorus*) chiefly used for nourishing cattle. Cotton is a staple commodity; and that of the Ahmood pergunna is of so superior a quality, that it generally brings the highest price in the markets of Bengal and China. Sugar, tobacco, and indigo, flourish luxuriantly in the province, and might be cultivated with great profit. Hemp and flax grow well in the northern districts; but are often raised chiefly for the sake of the oil contained in the seed, and an intoxicating drug called Chang made from the leaves. Mustard seed is raised in considerable quantities, and is greatly esteemed in pickles. Occasionally may be seen, in gardens, large crops of poppies, (the seeds of which are very commonly mixed by the natives in cakes and confections,) ginger, turmeric, fenue greek, and betel leaf, extensive fields of capsicum or chilies, and large tracts of yellow cossumba, (*carthamus*,) which yield a valuable red dye. In those places where there is no cocoa nuts, various shrubs and plants are cultivated for producing oil, especially the sesamum, and ricinus, palma Christi. The water melons, especially those of Baroche, are superior to any in India. The white, red, and curling mulberry flourishes in the gardens; and the cuttings require only to be put into the ground in the rainy season, where they take root, and grow up withour farther trouble. The bamboo grows wild in most districts, is frequently planted in hedges around the villages, and in seasons of scarcity sometimes furnishes an article of food. Mango, tamarind, and banian trees are to be found in most parts of the province. One of the last mentioned, (the banian or *ficus indicus*) the most magnificent tree of the kind in India, grows on an island in the river Nerbudda; and has nearly 1350 trunks, all traced to one parent stem, froming a canopy of verdant foliage, impenetrable even to a tropical sun, extending over a circuit of 2000 feet.

Many milch cows and buffaloes are reared in the villages; and ghee, or clarified butter, forms a principal article in the markets of Guzerat. Many horses also are bred in the province; and those of Cutch and Cottywar are held in great estimation. The oxen of Guzerat are accounted the finest in India. They are perfectly white, with black horns, a delicately soft skin, and eyes not inferior in lustre to those of the antelope. They will travel 10 or 12 miles a-day successively for a considerable time, under a load of 200 or 300 lbs.; and are fed upon straw, grass, cotton seed, or oil cake. Those which are reared in the northern districts are of superior size, strength, and docility; and some of them are capable of travelling in a hackery (or light cart) 30 or 40 miles a day. A more ordinary breed is employed in agriculture, and in the conveyance of merchandize; and others, of all different colours, as in other parts of Hindostan, are to be found in the province. The uncultivated and wood tracts abound in wild animals of various kinds. Lions, though not generally supposed to be found in the country, have been seen even in the vicinity of Cambay; and tigers are very common, sometimes so large as to weigh 250 lbs. Leopards, hyænas, wolves, foxes, jackals, and wild hogs, are the ordinary inhabitants of the swamps and jungles. Deer, elks, guanas, antelopes, hares, cameleons, porcupines, &c. are the most common kinds of game. Monkeys and squirrels are every where abundant, and remarkably tame. The former, particularly, often inhabit the towns, where they are generally protected, and in some places are revered as sacred animals. They are sometimes rendered instruments of a bloodless, but sufficiently malicious revenge among neighbours. A handful of rice, or other grain of which the monkeys are fond, is thrown upon the roof of the house of the obnoxious person, about the commencement of the wet season; and, in order to get at the grain which has slipped under the tiles, these mischievous animals soon uncover the whole habitation, at a time when labourers being generally occupied in repairing the houses, it may be impracticable for the hapless owner to have his home secured from the heavy torrents which are beginning to fall. Of the birds of prey, the most common are hawks and brahminee kites, which last are so remarkably voracious, as sometimes to dart upon a dressed fowl, or other food, while the servants are carrying it from the kitchens, (which are frequently at a little distance from the house,) to the dining-table. There are bats of an extraordinary size, (nearly six feet between the tips of the extended wings,) called flying foxes, and extremely disagreeable in smell and aspect. Peacocks, doves, and green pigeons, assemble in flocks around the villages, and are almost as tame as poultry in a farm yard. Partridges, snipes, woodcocks, wheatears, &c. are very abundant; and there is a great variety of water-fowl in the lakes and rivers, particularly storks, cranes, quails, flamingoes, pelicans, ducks. The sahras and cullum (*ardea virgo* of Linnæus) are very stately birds, generally six feet high, of an azure hue, with crimson coloured heads. But the florican, or curmoor, (*otis houbara* of Linnæus,) is at once the most elegant of Indian birds, and exceeds all other wild fowl in delicacy of flavour. It is distinguished by its lofty carriage, variegated plumage, and especially by a tuft of black feathers falling gracefully from its head. Lizards are abundant in Guzerat, and many of them are extremely beautiful. Serpents are found in great numbers and varieties; and some of the largest kinds, which are accounted harmless, are held sacred by the natives as guardians of the spot which they frequent, are allowed to occupy the gardens. One of the most venomous is the cobra de capello, or coluber naja, which is very common in Guzerat. There are many varieties of water snakes, (some of them spotted with the most beautiful colours,) which seize upon the frogs, lizards, young ducks, and water rats, and are in their turn devoured by the larger water fowls. Locusts, though less destructive than those of Arabia and Africa, are frequent visitors in the province; and leave every vegetable substance over which they pass stripped and browned, as if scorched with fire. The large locust, called "the creeping leaf", and which has been described under the article GUIANA, is common in Guzerat.

The principal towns in the province are Ahmedabad, Surat, Cambay, Baroche, Baroda, Dhuboy, Gogo, and Chumpaneer. They are generally in a ruinous condition, presenting, in their decayed palaces, tottering minarets and mouldering aqueducts, many vestiges of their former splendour. Their commerce has never been so flourishing as it was under the Mogul government, even in the times of its most violent convulsions. The principal trade of the province is carried on with Bombay. The chief exports are cotton, piece-goods, and grain; and the imports consist mostly of sugar, raw-silk, pepper, cocoa nuts, cochineal, woollens, and bullion. Almost all castes in Guzerat, excepting the Brahmins and Banyans, occasionally follow the occupation of weaving; which, together with the labours of agriculture, employs the greatest number of the more industrious of the lower classes. Fortifications were formerly very numerous in the province, and are still preserved in the more remote quarters. The natives every where live in towns or villages, for security against banditti and wild beasts. A single farm house, or separate cottage, is rarely to be seen; and, at night, the cattle are always brought within the hamlet, which is commonly surrounded by a mud-wall or bamboo hedge. The larger towns are usually situated near an extensive lake, the banks of which are adorned with Hindoo temples and caravansaries, and its surface covered by the various kinds of lotus. The houses, especially in the villages, are rarely built of brick, and provided with tiled roofs, but chiefly constructed of mud, and thatched with straw or reeds.

As many parts of Guzerat have never been subdued by any invader, the natives there retain their original character unchanged; but in the maritime district, in consequence of the many sea ports and commercial advantages, which have attracted strangers of all descriptions, the province contains a greater variety of castes and religions, than any other in Hindostan. It is commonly believed among the natives, that the province was originally peopled by the rude castes which still exist, and which are known by the names of Cooles and Bheels; but neither record nor tradition remains respecting their religion or government in their primeval state. In the town of Rajpeepla, however, the Rajpoot successor is still formally invested with the nominal sovereignty by a family of Bheels descended from their original chieftains. When the Rajpoots acquired the ascendancy, the most powerful of their princes resided at Neherwallah, (or Putten,) on the northern frontiers; and three dynasties are said to have successively occupied the throne, from which many of the modern Gracia families pretend to trace their descent. The Gracias are a numerous class of landholders in some parts of the province; and in others only possess a sort of feudal authority over certain villages and districts. They are described as consisting of four castes or families,—the Coolees, the Rajpoots, the Seid Mahommedans, and the Mole Islams or modern Mahommedans. The places principally occupied by the Gracias are Rajpeepla and Mandwee, the former south, and the latter north of the Ferbudda river; Meagam and Ahmode, between the Nerbudda and the Myhi; and Mandowee or the Taptee. Many tribes of them also reside in a kind of independent state on the rugged banks of most of the rivers, and in different parts of the peninsula. Criminals, who fly to their haunts for refuge, are readily incorporated among them; and all of them are habitual plunderers, forming one half of the population north of the Myhi. Of all the banditti who infest the province, the most cruel and untameable are the Coolees, who maintain amidst their fastnesses an armed independence, and plunder without distinction all who travel without an escort, or whom they are able to master. They are taught to despise all approaches to civilization; and are said to hold cleanliness in the utmost contempt, as a mark of cowardice. They are well mounted, and often roam in troops to a distance from their own settlements, to plunder villages or surprise travellers. Their own villages, at the same time, are large and populous, their fields inclosed, and their lands in general in a state of good cultivation. The Rajpoots are of a high caste, and are well bred to the use of arms. They are athletic in their persons, faithful to their engagements, magnanimous and brave above most other natives of India, and make the most excellent soldiers. They chiefly inhabit the districts north of the Nerbudda; and the great body of them occupy the province of Ajimeer, where they have never been subdued by the Mahommedans, and where they preserve in their strongholds and fastnesses the original manners of the Hindoo race. Their country is said to resemble greatly the more habitable mountainous tracts of Swisserland, and to afford some of the grandest and most picturesque scenery in India. The Bheels are like the Coolees, savage robbers, but generally poorer; and inhabit chiefly the districts around Turcaseer. The high Moguls or Mahommedans, especially those who inhabit the towns along the coast, are a polite and respectable people. In all the larger towns are found a singular race, who are Mahommedans in religion, but Jews in features, manners and disposition. They are called Borahs, and form every where a distinct community. They profess a total uncertainty of their own origin; but Boorhanpour, in Khandesh, is the rendezvous of the sect, and the residence of their moulah or high priest. They are noted for their address in bargaining, their minute parsimony, and constant attention to gain. They are the principal traders in the commercial cities, and are found straggling over the whole province, and the other western parts of Hindostan, as itinerant pedlars. In Guzerat is found, also, the greater part of the Gabres or Parsees, or worshippers of fire, who inhabit the continent of India, and who preserve the slender remains of the religion of the Magi; (See Gabres.) Of the proper Hindoos there are many castes and sects in Guzerat. The different families of Brahmins, settled in the province, amounted to 84 in number, and are named after the places of their ancestors nativity or inheritance. Each of these has several subdivisions, and innumerable distinctions, which prevent the members of one from intermarrying with another. The Banyans, or Vaneeya, are very numerous in Guzerat, and are also separated into many subdivisions. They are all merchants, and frequently travel to very distant countries, where they remain for several years, in the prosecution of traffic, and then return to their families with the gains of their adventure. Their language, the Guzeratee, which is nearly allied to the Hindee, is well known in all the great Indian markets, and forms the chief medium of mercantile intercourse in that continent. A singular custom among the Guzerat merchants may here be noticed, namely, that when any of them finds himself failing in trade, he sets up a blazing light in his house or shop; absconds, till his creditors have examined into the state of his property; and wears the tail of his waist-cloth tucked up, till they have acquitted him of all suspicion of dishonesty. Persons, who take this step in time, so as not to injure their creditors much, are held in great esteem, and are so frequently observed to be subsequently prosperous, that some have been known, in hopes of future good fortune, to set up the sign of bankruptcy without any necessity. The class of Bhauts, or Bharots, abound more in this province than in any other part of India. They are a very honourable tribe, and are principally occupied as historians, heralds, soothsayers, recorders of births and deaths, itinerant bards or minstrels, trading or begging on their way. In this last capacity, they repeat verses (which are either of their own composition, or selected from the Hindoo legends) with a pleasing modulation of voice, and gracefulness of action; and one of them is generally connected with the household of every Hindoo rajah or Mahratta chief, attending them on days of public ceremony, enumerating their titles, and proclaiming their praises They also become guarantees of treaties between princes, securities for bonds between private persons, or cautioners for the payment of revenues from districts, and farmers of the taxes. They receive an annual stipend, or a per centage from the districts, villages, or individuals, whom they thus guarantee; and, upon signing the agreement, add the figure of a dagger as their seal, and as an emblem of the fatal consequences attending a breach of contract. Should any party fail in the obligation, the Bhaut, who had offered himself as guarantee, proceeds to the house of the defaulter, and there destroys himself or one of his family, imprecating the vengeance of the gods upon the heads of those, who had compelled him by their misconduct to commit the deed of desperation. To be the object of these imprecations, is accounted by the Hindoos the most direful of all catastrophes; and hence the security of a Bhaut is the strongest and most sacred of all bonds. They are frequently also engaged in agriculture; but, as a privileged class, are exempted from all payment of taxes; and, when any attempts have been made to subject them to assessments, they do not fail to murder some of their tribe, with the usual imprecations on those who have infringed their rights. The Charons are nearly allied to the Bhauts in manners and customs; and, being generally possessed of large droves of carriage cattle, they carry on an inland traffic in grain to a considerable distance. They are frequently hired for the protection of travellers; and, when attacked by banditti, they take a solemn oath to die by their own hands, if any injury be done to the persons under their care. So great is the veneration in which they are held by the superstitious natives, that this threat of suicide is generally effectual in restraining the most ferocious plunderers. The Ungreas, whose profession is that of money-carriers, are of all castes, and generally athletic and well armed. Though extremely poor, they are remarkable for their honesty in conveying the largest sums. They conceal the money in their quilted clothes; and though rewarded for their services only with a small pittance, they will fight with the utmost desperation in defence of the property with which they are entrusted. In the northern and western parts of the province, is a class named Puggies, whose business it is to trace the steps of a thief, and they are so expert in the office, that, if set upon the pursuit early in the morning after the theft has been committed, before many people have been moving about the vicinity, they seldom fail to point out the village where the thief has taken refuge. The Dheras of Guzerat are similar to the Pariars of Malabar, and are obliged to live apart from the other inhabitants. They live on all kinds of carrion, and are much addicted to pilfering and intoxication. They are compelled by ancient custom to serve the state and travellers as carriers of baggage; and also to act as scavengers for the removing of filth from the roads and villages. The Koonbees, which is the name given in Guzerat to the Hindoos of the pure Sudra, or fourth caste, form the great body of the agricultural peasantry; and are supposed to have emigrated originally from Ajimeer, or Hindostan Proper. They hold portions of government land; and are called Patells, in distinction from the Gracias. They are peaceable, industrious subjects under every change of rulers; and, as they seldom repair to the cities, their manners are altogether simple and inoffensive. They rarely leave the village where their fathers lived and died, but continue in the same place, to plough the fields, and reap the harvest, and tend the cattle, while their women are employed in spinning cotton, grinding corn, and preparing the usual repast of milk, pulse, and other vegetables. Too large a proportion of the produce of their lands is collected for the government and subordinate chiefs; but still a sufficiency generally remains for the supply of their wants, which are extremely few and simple. In the more remote districts, particularly, their mode of living is remarkably primitive. A hut built of mud, and thatched with straw, is the ordinary habitation of the villager. A few earthen pots for cooking, a large jar of unburnt clay for holding grain, another of burnt clay, for holding water, and a glazed jug for holding oil, form the chief part of his furniture. A couple of yards of cotton cloth tied round the middle, and sometimes a turban on the head, composes the whole clothing of the men; and a long piece of similar cloth, put on in graceful folds, is the usual dress of the females.* They testify great hospitality to strangers, who are usually presented at the entrance of the villages with fruit, milk, butter, fire-wood, and earthen utensils; and sometimes compelled, at their departure, to take with them one day's provisions. They are a contented people, and their condition tolerably comfortable in seasons of peace; but they have no idea of liberty, and are subjected to every species of suffering in time of war. But

* It is a universal practice among all the Mahommedans of both sexes, and the Hindoo males throughout Guzerat, to smoke tobacco; except the Brahmins, who take snuff very freely.

wherever British influence extends, their comforts are increased, and their security better provided for. In the north-western quarters, many barbarous practices prevail among them; and among the Coolees and Rajpoots, particularly, besides what may be called the prescribed cruelties of their religion, it is not uncommon for many persons of both sexes to cut off their noses, as a security against the malignant influence of witches. The unnatural practice of putting to death the female infants, which prevailed among the Jahrejahs, a race of Rajpoots in the peninsula of Guzerat, was abolished in 1808, by the humane exertions of Jonathan Duncan, Esq. late governor of Bombay, and of Colonel Walker, British resident in the province;* and within the districts acquired by the East India Company, many other degrading customs are gradually disappearing. The province of Guzerat, in short, presents among its different inhabitants instances of the extremes of civilization, exhibiting all the rudeness of the pastoral and almost of the savage state, along with the wealth and luxury of commercial cities. It affords equally striking specimens of the extremes of population, which is thinly scattered over the western districts, but unusually crowded in the vicinity of Surat, and some of the other cities. The whole number of inhabitants in this extensive province is estimated at six millions, in the proportion of one Mahommedan to ten Hindoos. See Rennel's *Memoir of a Map of Hindostan:* Milburn's *Oriental Commerce;* Hamilton's *East India Gazetteer;* and Forbes's *Oriental Memoirs.* (*q*)

GWALIOR, Gualior, or Gualiar, is the name of a strong fortress of Hindostan, in the district of Gohud, and province of Agra. This fort stands on a hill about $1\frac{6}{10}$ mile long, 300 yards wide at its greatest breadth, and 342 feet high at its north end. The sides of this hill are nearly perpendicular, and a stone parapet is carried all the way round close to the brow of it. At the north end of the hill, and near the middle of the fort, are two remarkable pyramidal buildings of redstone, in the ancient Hindoo stile of architecture. The only gate to this fort is at the northern extremity of the east side, from which there is an ascent to the top of the rock by several flights of steps. The garrison is supplied with excellent water, from several natural cavities in the rock; and about half way up the rock, on the outside, there are many artificial excavations, containing the figures of men and animals carved out of the solid rock.

The town is situated on the east side of the hill. It is large and populous, and contains many good stone houses. The stone is obtained from the neighbouring hills, which surround the fort like an amphitheatre, at the distance of from one to four miles. They chiefly consist of schistus, with apparently a large portion of iron, and their surface is rugged, and nearly destitute of vegetation. The small river Soonrica rises to the eastward of the town, and beyond it is the tomb of Mahommed Ghous, a learned man; it is a handsome stone building, with a cupola covered with blue enamel. Within the inclosure of this monument is another tomb erected to the memory of Tan-Sein, a great musician. The leaves of the tree which overshadows this tomb, are supposed by the vulgar to give great melody to the voice when chewed. About 700 yards from the northern extremity of the fort, is a conical hill, having on its summit two high pillars joined by an arch, which is supposed to be of very ancient workmanship.

The town of Gwalior carries on a considerable trade in cloth with Chanderi, and also in indigo. About 14 miles from Gwalior, on the road to Narwar, is a mine of iron, near the village of Beerch, which is worked to advantage. Gwalior was always considered by the natives as impregnable, till it was taken by escalade by Major Popham, on the 3d August, 1780. In the time of the Mogul government, it was a state prison, where the obnoxious members of the family were secured, and a large collection of lions, tigers, and wild beasts, was kept here for their amusement. It was appropriated to the same purpose by Madajee Sindia, who, on account of its security, also made it a grand depot for artillery and military stores.

When the Mogul empire was dismembered, this fort came into the possession of the Ranah of Gohud, from whom it was taken by the Mahrattas. After the British took it in 1780, it was given up to the Ranah. Sindia invested the fort, and after a siege of many months, he succeeded in taking it by corrupting part of the garrison. In 1804, it was ceded to the British; but, by the treaty of 1805, it came into the possession of Dowlet Row Sindia. Distance from Agra 80 miles; from Delhi 197; and from Calcutta 480. East Long. 78° 14′, and North Lat. 26° 18′. See Hamilton's *Gazetteer.*

GYMNASTIC Exercises. See Athletæ.

GYMNOSOPHIST is a word of Greek origin, and literally signifies a philosopher who goes naked. It is particularly applied to the sages of India, who are understood to have wandered from place to place, either wholly without clothing, or only partially covered. Hence the *sapientes Indiæ* are described by Quintus Curtius, under the designation of *genus horridum et agreste.*

Though the Gymnosophists are usually considered as belonging exclusively to India, they were not in ancient times confined to that part of the world. There were likewise African Gymnosophists. These last inhabited a mountain in Ethiopia, near the river Nile; and they appear to have lived in celibacy and solitude, subjecting themselves to various penances and privations, after the manner of hermits or monks in more modern times. They were understood to hold an immediate intercourse with the immortal gods. If any one had killed his neighbour by accident, he had recourse to those recluses for absolution, and received it, upon the performance of certain ceremonies which they required. They were skilful in the medical art, and Lucan ascribes to them several important discoveries in astronomy. Indeed, it may be inquired, whether there were not Gymnosophists (using that term in a more general sense) in every nation, the early history of which has come down to us in any thing like detail, or with any measure of certainty; and whether the Brahmins of India, the Priesthood in Egypt, the Persian Magi, and the Druids of Great Britain, were not all branches of the same philosophical school, holding certain doctrines in common, though distinguished from one another by the degree of improvement to which they had respectively attained, or the political and moral circumstances of the countries to which they belonged.

One principal tenet of the Gymnosophists appears to have been that of the metempsychosis, or transmigration of souls; whether we understand by this term the passage of the soul from one human body to another, or the transmission of the immortal spirit through the bodies of different animals, till having been defæcated and refined in its progress, it enters at length into the immediate and beatific presence of the Supreme Divinity. The doctrine of the metempsychosis was afterwards taught with greater celebrity by Pythagoras; and, as the philosopher just named is known to have travelled into India, there is reason to believe that he borrowed it from the Gymnosophists. In many features of their character, however, the *sapientes Indiæ* appear to have resembled the stoics. They undervalued and despis-

* See Cormack's *Account of the Abolition of Female Infanticide in Guzerat.*

ed the goods of fortune, and lived chiefly in the woods and desert places, supporting themselves upon the spontaneous productions of the earth. Hence they are called, by Clement of Alexandria, *alobii*, or *hylobii*; and he relates of them, that they inhabit neither cities nor villages, but eat acorns, and drink water out of their hands. They abstained from marriage and the society of women. They held that every man was suffcient for himself, neither dependant upon others for the supply of his wants, nor requiring their assistance. They cherished a spirit of lofty independence. When Alexander the Great sent one of his captains to a body of the Gymnosophists, inviting them to a conference, they replied, that it was not their practice to visit any one, but that if the Macedonian king had any thing to communicate, they were ready to receive him. They maintained the lawfulness, and even the duty of suicide, and attached a degree of infamy to a lingering and anticipated dissolution. "Apud hos," says Quintus Curtius, "occupare fati diem, pulchrum; et vivos se cremari jubent. Quibus aut segnis ætas, aut incommoda valetudo est, expectatam mortem pro dedecore vitæ habent. Nec ullus corporibus, quæ senectus solvit, honos redditur. Inquinari putant ignem, nisi qui spirantes recipit." *De Reb. Gest. Alexand. Magn.* lib. viii. c. 9.

Apuleius *Florid.* lib. i. thus describes the Gymnosophists: 'They are all devoted to the study of wisdom, both the elder masters and the younger pupils: and what to me appears the most amiable thing in their character, is, that they have an aversion to idleness and indolence; accordingly, as soon as the table is spread, before a bit of victuals be brought, the youth are called together from their several places and offices, and the masters examine them what good they have done since the sunrise. Here one relates something he has discovered by meditation; another has learnt something by demonstration; and as for those who have nothing to allege why they should dine, they are turned out to work fasting." (*h*)

GYPSIES. Towards the earlier part of the fifteenth century, the attention of various European nations was attracted towards a wandering tribe of people, entirely different in appearance and manners from the established inhabitants, and speaking a language peculiar to themselves. None could account for their origin; neither could the route by which they had been introduced be explained: they took up a temporary abode in places most congenial to their disposition, and were gradually dispersed throughout the continent, and among the principal islands. During their first introduction, and the periods immediately succeeding it, the strangers received various appellations, resulting either from corrupted dialects, or the opinions of those among whom they dwelt. But by common consent, conjoined with some imperfect traditions regarding their history, the name of Egyptians, or Gypsies, has been long bestowed upon them.

In so far as we are enabled to collect, these people have undergone no alteration with the lapse of centuries; they are a rude, illiterate, uncultivated race at this day; time and climate have been alike ineffectual in producing a change; they are the same in Siberia, in Turkey, in India, and in Europe: and if their vices have not increased, neither has there been any amelioration in their character. M. Olivier found a race of gypsies in Aleppo, and Lieutenant Pottinger saw tribes resembling them in Beloochistan. The gypsies are of a dark complexion, symmetrically formed, and rarely subject to deformity; they have beautiful white teeth, and the women fine black eyes, but the men are characterised by a scowling aspect. They are not remarkable for strength; they are swift of foot, but decidedly deficient in courage. The swarthiness of their colour is undoubted, and the earlier historians call them "black horrid looking men;" but the complexion of those who are kept cleaner than usual is evidently lighter: besides, there can be little doubt that an alteration in this respect may be slowly effected by the temperature of the atmosphere, or in the course of successive generations.

The gypsies testify an indifference to the quality of their food, unknown among the least civilized tribes of Europe. Carrion is a dainty to them; a murrain among cattle, whereby they may obtain abundance of flesh from animals dying of disease, is a joyful and profitable event; and they are even disposed to eat it almost raw. They have been accused of cannibal appetites; and as the existence of cannibals in several parts of the world is beyond dispute, we are not entitled to deny the fact with respect to gypsies. In the year 1782, after having for a length of time disturbed the tranquillity of Hungary, where they are numerously disseminated, many were brought to trial, and convicted of various crimes, among which were robbery, murder, and feeding on human flesh. It is recorded that they confessed having killed three people, and ate their bodies in great festivity, among other delicacies, at a wedding; that they preferred young persons from sixteen to eighteen years of age, and burnt their bones for fuel. The band to which these malefactors belonged, had subsisted 21 years, during which 84 individuals had perished by their barbarity. But the punishments inflicted on the criminals, were too shocking to admit of description. Thirteen were put to death at Frauenmark, in August; 15 at Kameza, in September; and at Esabrag 13 more, including 18 women who were beheaded. Many others were condemned, but respited, and 150 remained in chains. Yet whether these gypsies were actually guilty of such enormities, or whether they were the victims of persecution on slight grounds of suspicion, appears to us problematical. Amidst the numerous accusations of European cannibalism, few if any have been satisfactorily proved; and although the Asiatic gypsies are indirectly charged with the same depraved propensity, it is only on very slight evidence. Thus they have an immoderate desire for ardent spirits; and tobacco is so grateful, that they will be content to abstain from every thing else for a whole day, for a single leaf of it.

Gypsies have no settled abode, and never dwell in cities. They live in huts, or even in excavations of the earth, generally on the side of a hillock, that has a southern exposure. A roof is formed of rafters, overlaid with turf, and a woollen cloth is often drawn across the aperture left for a door. Some of the more miserable only shelter themselves in forests, or behind hedges, in the warmer climates. A fire occupies the middle of the hut, around which the children lie naked; and indeed the whole tribe, although delighting in finery, go very scantily clothed. But if a single gaudy article can be obtained, the rest is disregarded; whence a man is sometimes seen on the continent in an old red silk coat, or a woman adorned with glaring ribbons, while their other apparel consists of rags. Linen is a scarce commodity among them, for the females can neither sew nor spin.

None of the gypsies are agriculturists. Where they have, by unusual fortune, and by abandoning their nomadic life, become proprietors of spots of ground, the cultivation of it is left to others. Their own professions are, gold washing in Hungary, at which they are very expert, farriery, rude occupations in smith work, and, in Britain, they are for the most part employed in the lowest branches of that art. Their tools and materials are alike indifferent. Nothing is done but on a small scale; and it is observed, that the artificer always sits down cross-legged to his work, which is considered as denoting the eastern origin of his race. They were formerly employed abroad in the execution of criminals, wherein they displayed a skill in the art of torturing their fellow-creatures, corresponding with their own innate pusillanimity. Many dealt in horses, but they practised such ingenious deceptions, and to so great an extent, that a royal ordinance prohibited this part of their profession. Their females form a considerable portion of the dancing girls of India. They combine music with their allurements; and most of them, both in that peninsula and Turkey, as likewise in Spain, subsist on the wages of prostitution. Every where the character of their dances is the same; and, in Spain, one of them called Maguindry is prohibited under severe penalties. The men and women sometimes bring forward dramatic exhibitions, for the performance of which they are called before the houses of the wealthy. The women, as is well known, pretend to skill in divination, and tell the fortunes of the credulous from palmistry, physiognomy, or moles on the skin; hence the origin of the beautiful engraving of *La Zingara*. So long ago as the year 1531, we find an English statute narrating, "that before this time many outlandish people, calling themselves Egyptians, using no craft nor feat of merchandize, have come into this realm, and gone from shire to shire, and place to place, in great companies, and used great, crafty, and subtile means to deceive the people, bearing them in hand, that they, by palmistry, could tell men and women's fortunes, and so, many times by craft and subtilty, have deceived the people of their money, and also have committed many heinous felonies and robberies, to the great hurt and deceit of the people they have come among. It is singular, that at Tobolsk in Siberia, their practice and professions are the same. "They watch every traveller," according to Commodore Billings, "and pretend to explain the mysteries of futurity by palmistry or physiognomy. The peasant dreads their power, and, from motives of fear, contributes to their support, lest they should spoil his cattle or horses." Thus, in the western parts of Europe, and the eastern parts of Asia, at an interval of nearly three centuries, the gypsies are distinguished by corresponding features, scarcely modified by the people among whom they seek an asylum.

This tribe is utterly unacquainted with science and literature. The scanty knowledge of their forefathers remains with them unimproved. A few of those in Spain, however, pretend to knowledge in medicine or surgery; and the females in the neighbourhood of Calcutta visit that and other towns, and prescribe for the complaints of their own sex. They have no settled principles of religion; they are Turks with Turks, and Christians with Christians. It does not appear that they celebrate any religious rites, or entertain the common sentiments of mankind in regard to a future life, or places of reward and punishment. The son of a more civilzied Transylvanian gypsey having died at school, and being about to receive Christian burial, the officiating priest inquired, whether the survivors believed that the deceased would rise again at the last day? "Strange supposition!" they answered, "to conceive that a carcase, a lifeless corpse, should be reanimated, and rise again; it is no more likely to happen, in our opinion, than to the horse we flayed a few days ago." Their children, however, are circumcised in Turkey, and baptised in Europe.

Their marriages, which take place at a very early age, are void of ceremony, and rather resemble temporary connections than a union for life. One of their own number performs the part of priest, and thus gives it the sanction of publicity. The youth then forsakes his father, along with his bride, and if capable of mechanical exercises, he provides a pair of tongs, a stone for an anvil, a hammer and a file, to commence the profession of smith, after the fashion of his predecessors. In India a scene of riot and intoxication precedes the establishment of the parties, and certain mystical ceremonies attend the marriage. The men are extremely jealous of their wives, who are kept in strict subservience, and are in danger either of corporal punishment, or absolute dismissal, if they happen to displease them. Both sexes are extravagantly attached to their offspring; and, in some countries, it frequently happens that the readiest method of obtaining payment of the father's debts is by arresting his children. No education is given to the young, unless it be instruction in obscenity, and in the art of stealing dexterously. Infants of five or six months old are supplied with spirits in India, and their mothers, while indulging a fatal propensity to the same beverage, suckle them until they have seen as many years. In Europe these people are remarkably healthy, and escape those epidemical maladies which sweep away thousands around them; and even when they labour under dangerous diseases, they pertinaciously refuse medical assistance. They make loud lamentations at funerals, and carry the body of the leader of their horde with great respect to the grave.

The language of the gypsies, though it has necessarily undergone many changes from their successive migrations, and the corruptions unavoidable from living among others, is peculiar to themselves in Europe; but it contains many affinities with a dialect of particular castes in Hindostan. This fact receives the stronger corroboration, from having been first recognized by some young men, natives of the coast of Malabar, who were prosecuting their studies at Leyden. Numerous expressions were compared by them, and the same has since been carried to a greater extent by literary men residing in India. Etymologies are in general to be distrusted, for they frequently lead to the most ludicrous and absurd mistakes; but we cannot deny, on the other hand, that the affinities of languages spoken by nations separated far asunder, may be found so strong and decided, that we shall find it difficult to deny them a common origin. On this subject Grellman remarks, "with respect to the construction and inflection of the two languages, they are evidently the same; that of Hindostan has only two genders—the gypsey the same. In the former, every word ending in *j* is feminine, all the rest are masculine; in the latter it is the same. That makes the inflexions entirely by the article, and adds it to the end of the word; the gypsey language proceeds exactly in the same manner. Finally, likewise, excepting a few trifling variations, this identical similarity is evident in the pronouns." Many other instances of mutual correspondence may be produced, almost all tending to a similar purport, as may be seen at large in the writings of those authors who discuss this subject.

The gypsies of Europe acknowledge a chief or leader, who usually assumes the dignified title of wayvode or prince, duke, count, or lord, according to the countries frequented by them. The most exalted of these titles is given to one who presides over the gold washers in Hungary, and the dignity is elective, but with some regard to descent from a former wayvode, and also to the stature and apparel of the individual chosen, who is commonly about the middle age. He is merely lifted up three times with the loudest acclamations, amidst a numerous concourse of the tribe; his wife is treated with similar ceremony, while the dignity of both is recognized by all present. The titles assumed by these people are of ancient date: they appear in the fifteenth century; and in the commencement of the sixteenth, King James IV. of Scotland grants a pass and recommendation to the king of Denmark, in favour of the tribe of Anthony Gawino, an Earl from little Egypt. He specifies that this miserable train had visited Scotland by command of the Pope, and having conducted themselves properly, they wished to go to Denmark: He therefore solicited the extension of his royal uncle's munificence towards them; adding, at the same time, that these wandering Egyptians must be better known to him, because the kingdom of Denmark was nearer to Egypt! In Hindostan, the gypsies have a chief who has very little direct authority over them, but he controuls the establishment of sets who profess dramatic exhibitions, and draw a tribute from their profits. They even acknowledge a rude judicial procedure before a court of five persons, or a general assembly, and any individual, for petty offences, has to pass the ordeal of applying a hot iron to his tongue. If conviction follows, the culprit is generally sentenced to pay a fine in liquor, of which his judges participate; or, as a mark of the highest ignominy, he may be condemned to have his nose rubbed on the ground.

Almost in every country throughout the globe, the gypsies have long been the objects of reproach and detestation. From their first appearance, they have been wandering outcasts and universally refused a settlement in towns, or in their immediate neighbourhood. The dislike manifested towards them, though attended with less barbarous consequences, may be assimilated to the detestation which has accompanied the Jews since the destruction of Jerusalem. Those atrocious cruelties, however, that stain the annals of nations, cannot with confidence be charged on this nomadic tribe. If their crimes are numerous, they are of a petty description, directed against the property more than the persons of their fellow creatures. The gypsies have no where manifested virtuous principles, or any desire to excel; the depravity of the parents passes to the children, who inherit, along with it, the detestation of the people among whom they seek an abode. In foreign states, many attempts have been made to reclaim them, but there, as well as in our own island, they have been for the most part indiscriminately condemned to exile. Neither have the politic and patriotic views of the governments, thus directed, been attended with the success which they merited.

In the year 1782, the Empress Maria Theresa promulgated an edict, prohibiting gypsies from dwelling in tents, and enjoining them to settle in fixed abodes. They were forbidden to wander about, to allow their children to go naked, to deal in horses, and to wear cloaks, whereby thefts might be easily concealed. They were also commanded to abstain from feeding on carrion, to frequent the churches, and to conform to the manners of the inhabitants of the territory where they resided. Their usual name was to be abolished, and in future they were, instead of gypsies, to be called *new boors*, and occupy themselves in the active prosecution of agriculture. These regulations, wisely conceived, being ineffectual, severer enactments followed. It was decreed, that no gypsey should be permitted to marry, unless he could shew himself in a situation to maintain a wife and family; and that those who had children should be forcibly deprived of them, in order that the rising generation should have the benefit of a better mode of education. The latter part of this ordinance was carried into effect, and in certain districts, all the children above five years of age were conveyed away in waggons from their parents. But it is not evident that such compulsory measures were beneficial; and the failure of others in the eastern extremities of Russia, nearly at the same period, though more gentle, prove that it will be extremely difficult to reclaim the gypsies to habits of industry. Experience daily proves, that mankind, who have roamed at liberty, are averse to a settled residence, and that the controul of those living in society is an arduous undertaking, while their management is easily accomplished should they be only in an isolated state. With the diminution of their own hordes, a gradual incorporation will take place with those around them, and probably is insensibly doing so at this moment where they are least numerous. No accurate computation can be formed of the extent of the united tribes of gypsies dispersed throughout the world; for they are unequally distributed, and only partially known. Grellman conjectures, that those in Europe may amount to 700,000 or 800,000; of whom Twiss conceives 40,000 to belong to Spain: there are many in the Turkish empire, but few in the island of Britain, particularly north of the Tweed.

The history of the gypsies is an enquiry not less obscure than difficult; and it must be allowed, that even yet we have no conclusive authorities relative to its earliest period. Analogies certainly prove the eastern parentage of their tribes; but why they left their native soil, or how they penetrated into Europe and its more distant islands, we are unable to discover. It is commonly believed, that they migrated from Egypt; an opinion which has probably, received greater corroboration from their name than from other circumstances. But neither their size, complexion, manners, or appearance, correspond with those of any Eygptians described in ancient or modern history; hence, if we are to draw any argument from their name, we must say it arises from Egypt, being the last point of their departure from the East. Those observers who have most profoundly studied their history, find a striking resemblance between the gypsies and the natives of Hindostan: Should this hypothesis be correct, they may have reached the isthmus of Suez by the north of India, and crossed it into Egypt; a progress by no means impracticable, but which does not satisfactorily account for their immediate access to Europe. The time of their first appearance in this quarter of the globe is unknown; but towards the beginning and middle of the fifteenth century, they attracted general attention as a strange people. They are recorded to have frequented Germany in 1417; Switzerland in 1418; and they are spoken of as being in Italy in 1422. It is said that they were originally known in France by the name of Bohemians; and arrived at Paris on the 17th of August 1427. They travelled in hordes, generally of 70 or 100 persons, probably finding it expedient not to accumulate too much; and each horde had a leader, who assumed a title, which, however, has more the character of the West than the East. Rapidly spreading over Europe, they were at first believed to be pilgrims, chiefly from the Holy Land; and hence they both received protection and indulgence, and were treated with marks of veneration, wherever they went; but their real disposition speedily betrayed itself; they proved a lawless gang of depredators, deceiving the credulous, plundering their benefactors, and rendering themselves obnoxious to all civilized nations. Every arm was lifted against them; they were driven from place to place; and at length the very name of being a gypsey, was esteemed a crime deserving capital punishment. It is not unlikely, that the severity of the enactments directed against them had the effect of dividing and spreading their hordes still farther, to avoid the penalties of a permanent residence. But the barbarous and unsettled condition of the different European states was a powerful obstacle to the establishment of a vigorous police; and it is only in recent times, that the kingdoms, in which we dwell at peace, have been freed from vagabonds and beggars, who, invading the cottages of the peasantry, demanded alms in a manner that their inhabitants durst not refuse.

Gypsies are always included in the statutes respecting vagabonds; and in the year 1531, they were commanded at once to depart from England within sixteen days. The laws of Scotland exhibit repeated instances of the light in which they were subsequently viewed; for an ordinance of the Privy Council of 1603, converted to a perpetual act in 1609, decreed, that the whole race should quit the kingdom under pain of death. Nevertheless they found means to evade compliance; they continued roving about the country; and as is well known, one of them, having seduced the affections of a Countess of Cassilis from her husband, persuaded her to elope with him. In the criminal records, several of the same name as this adventurer appear to have been brought to trial for petty offences, and for being found in Scotland. Four gypsies, named Faa, were condemned to be hanged in 1613, though they seem to have had permission to remain. Two more of this name were tried in 1616; and in 1624, Captain John Faa, and five other men of his name, were sentenced to death. Their execution was followed by the condemnation of Helen Faa, widow of Captain John, Lucretia Faa, and nine females more, all to be drowned for being reputed Egyptians, for remaining in the kingdom, and having committed petty thefts. But this barbarous sentence was commuted to perpetual banishment. The terror of these trials quieted Scotland for nearly a century; and excepting a few itinerant gypsies, universally denominated tinkers, none are now to be seen. They are also gradually disappearing from England, where they seem inclined to be turbulent; and some years ago, we believe, that on the apprehension or punishment of one of their gang, they threatened to set fire to the town of Norwich. In a country so industrious as Britain, the residence of men who live in a state of idleness cannot be permanent; and they will either depart, or their habits will be assimilated to those around them, while they themselves are slowly absorbed in the great mass of the people.

# H.

HABEAS CORPUS, is a writ in the English law, of which there are various kinds, for removing prisoners from one court into another, for the more easy administration of justice. Such are the *habeas corpus ad respondendum*, *satisfaciendum*, *prosequendum*, *testificandum*, *deliberandum*, &c. when a prisoner is removed from an inferior court to be charged with a new action in the courts above; or when he is to be charged with process of execution; or when it is necessary to remove a prisoner in order to prosecute or bear testimony in any court, or to be tried in the jurisdiction wherein the fact of which he is accused was committed. There is also the common writ *ad faciendum et recipiendum*, otherwise called an *habeas corpus cum causa*, which issues out of the courts of Westminster Hall, commanding the inferior judge to produce the body of the defendant in a process, together with the day and cause of his caption and detainer, to *do and receive* whatsoever the king's court shall consider in that behalf.

But the most important writ of this kind, and the most efficacious for vindicating the personal liberty of the subject in all cases of illegal confinement, is that of *habeas corpus ad subjiciendum*. This is a high prerogative writ, and therefore, by the common law, issuing out of the court of King's Bench, not only in term time, but also during the vacation, by a *fiat* from the chief justice, or any other of the judges, and running into all parts of the king's dominions. Like all other prerogative writs, it must be applied for by motion, and does not issue of mere course, without shewing some probable cause why the extraordinary power of the crown is called in to the assistance of the party. And this is the more reasonable, because, when once granted, the person to whom it is directed can return no satisfactory excuse for not bringing up the body of the prisoner. This also, it will be observed, induces an absolute necessity of expressing, upon every commitment, the reason for which it is made; in order that the court, upon an *habeas corpus*, may examine into its validity, and act according to the circumstances of the case.

The law of England has always been extremely careful in asserting and preserving the personal liberty of individuals, which ought never to be abridged at the mere discretion of the magistrate, without the explicit permission of the laws. The great charter provides, that no freeman shall be taken or imprisoned, but by the lawful judgment of his equals, or by the law of the land; and many subsequent old statutes expressly direct, that no man shall be taken or imprisoned by suggestion or petition to the king, or his counsel, unless it be by legal indictment, or the process of the common law. The writ of *habeas corpus* affords an ample and effectual remedy in all cases of illegal confinement; yet this remedy was in danger of being rendered nugatory during the early part of the reign of Charles I. the court of King's bench having determined, that they could not upon an *habeas corpus* either bail or deliver a prisoner, though committed without any cause assigned, in case he was committed by the special command of the king, or by the lords of the privy council. This illegal judgment drew on a parliamentary enquiry, and produced the petition of right, 3 Car. I. which enacted, that no freeman shall be imprisoned or detained without cause shewn, to which he may make answer according to law. The evasions of this enactment, however, which were attempted in the following years, particularly in the case of Mr Selden, gave rise to the statute 16 Car. I. c. 10. § 8. whereby it was provided, that if any person be restrained of his liberty by order or decree of any illegal court, or by command of the king's majesty in person, or by warrant of the council board, or of any of the privy council, he shall, upon demand of his counsel, have a writ of *habeas corpus*, to bring his body before the court of King's Bench or Common Pleas, who shall determine whether the cause of his commitment be just, and thereupon do as to justice shall appertain. But other abuses now crept into daily practice, which in some measure defeated the benefit of this great constitutional remedy; and in the case of Jenks, who in 1676 was committed by the king in council for a turbulent speech at Guildhall, new shifts and devices were made use of to prevent his enlargement by law. These abuses gave birth to the famous *habeas corpus act*, 31 Car. II. c. 2. which has frequently been considered as another *magna charta* of the kingdom; and by which the methods of obtaining this writ are so plainly pointed out and enforced, that, so long as this statute remains unimpeached, no subject of England can be long detained in prison, except in those cases in which the law requires and justifies such detainer.

Sometimes, when the state is in real danger, a temporary suspension of the *habeas corpus* act is thought necessary; but, fortunately, it is not left to the executive power to determine when the danger of the state is so great as to render this measure expedient. For the Parliament only, or legislative power, whenever it sees proper, can authorise the crown, by suspending the *habeas corpus* act for a short and limited time, to imprison suspected persons without giving any reason for so doing. This, however, is an experiment which ought never to be resorted to, except in cases of extreme emergency. See Blackstone's *Comment.* B. III. ch. 8, and Jacob's *Law Dict.* by Tomlins, in which the reader will also find the substance of the provisions contained in the *habeas corpus* act. (*z*)

HACKNEY. See Middlesex.

HADDINGTON is a royal burgh of Scotland, and the county town of East Lothian or Haddingtonshire. It is situated on the small river Tyne, and consists of four streets which cross each other nearly at right angles. One of these has two branches, viz. the Fore and the Back Street, the first of which crosses the place of intersection. The streets are in general spacious and clean. The houses, particularly those in the Fore Street, are neat and well built; and in the suburbs are some elegant little villas. At the end of the Fore Street, at its junction with the Back Street, is a neat town house, erected from the designs of the late Mr Adam. The old abbey, which contains the parish church, is one of the principal ornaments of the town. This venerable pile was formerly the church of the Franciscan monastery, and was erected during the reign of Alexander II. In February 1355-6, the town and monastery, along with the church of the Minorites, were burned by Edward III. The parish church, which has lately been much improved and embellished, occupies the west end, and the rest of the building is in ruins. In the aisle, which forms the burying-place of the Maitland family, is a marble statue of the Duke of Lauderdale lying on a bed of state, and also the monument erected to John Maitland, Baron of Thirlstane, Lord High Chancellor of England, which contains an inscription from the pen of James VI. The Episcopalian chapel, built by private subscription, is neat and commodious. About a $\frac{1}{4}$ mile to the east of the town, near the suburb called Nungate, are the ruins of a nunnery, founded in 1178 by Adda, widow of Prince Henry, and mother of Malcolm IV. The bridge over the Tyne, which connects this suburb with the town, is built of stone, and consists of three arches. Several remains of the ancient fortifications of the town are still visible. Haddington had formerly a house of dominicans or black friars, who were introduced into Scotland in the reign of Alexander II.

Haddington sends a member to parliament along with Jedburgh, Dunbar, Lauder, and North Berwick. It is governed by a provost, three bailies, a dean of guild, a treasurer, and 12 councillors, and has seven incorporated trades. The principal manufacture carried on in Haddington was one of coarse woollen cloth; but it has some time ago been abandoned. The manufacture of starch was attempted by Mr Wilkie, jun. of Gilchriston, a public spirited individual, but it did not succeed. A new flour mill, driven by steam, has been built in the Nungate; and an extensive distillery is at present erecting on the bleachfield by Mr Dunlop, one of the partners of the distillery at East Linton. The town has also suffered considerable injury, from the removal of the extensive barracks in its immediate vicinity. The country around Haddington is extremely rich and beautiful, and is ornamented with many gentlemen's seats, the principal of which are Amisfield, one of the seats of the Earl of Wemyss; Clerkington, the seat of Mr Hepburn; Leadington, the seat of Lord Blantyre; Coulston, the seat of Lord Dalhousie; Alderston, the seat of Mr Stewart; and Letham, the seat of Mr Buchan Hepburn.

The following is the population of the burgh and parish in 1811.

| | |
|---|---|
| Number of inhabited houses | 671 |
| Do. of families | 1041 |
| Do. employed in agriculture | 379 |
| Do. in trade and manufactures | 389 |
| Males | 2002 |
| Females | 2368 |
| Total population | 4370 |

HADDINGTONSHIRE. See Lothian, *East*.

HADLEIGH, or Hadley, is a market-town of England, in the county of Suffolk, situated on the river Breton. Its principal ornament is its church, which is a handsome structure with a spire steeple, situated in the middle of the town. The altar piece of the church is very handsome. Guthrum or Gormo, the Danish chieftain, who was defeated by Alfred, embraced Christianity, and reigned over the East Angles for 12 years, was interred here in 889. The tomb, however, which is shewn as his, is supposed by Mr Gough to be of much later date. Twelve alms-houses for 24 aged persons were founded here in 1497 by William Pykenham, dean of Stoke College, who was rector of Hadleigh. This town formerly carried on a great trade in cloth; but its principal business is now that of spinning yarn for the weavers of Norwich. In 1811, the town and parish contained 509 inhabited houses, 529 families, and a population of 2592. See *Beauties of England and Wales*, vol. xiv. p. 211.

HADRAMAUT. See Arabia.

HADSJAR. See Arabia.

HAERLEM, or Haarlem, a town in the United Provinces, 12 miles west of Amsterdam, and $15\frac{1}{2}$ north of Leyden, is a place of considerable antiquity, and has experienced many vicissitudes in its history. In 1249, the citizens, having signalized themselves in the crusades, were rewarded with great privileges by William, king of the Romans, and Comte of Holland. At different times, especially in 1347 and 1351, it was almost entirely consumed by fire. In 1492, it was seized and pillaged by the faction of the Caes-en-brool, but was recovered by Albert, duke of Saxony, who punished the insurgents, and deprived the inhabitants of their privileges. At the request of Philip II. of Spain, it was erected into a bishop's see by Pope Paul V.; but, in 1571, the citizens embraced the Protestant faith, and submitted to the Prince of Orange. It was besieged in 1572 by Frederick of Toledo, son of the Duke of Alva, and for the space of eight months made a most desperate resistance. Even the women of the place formed themselves into regular battalions, and shared in all the duties of the garrison. At length, worn out by famine and fatigue, they agreed to surrender, upon condition that the lives of the garrison and of the citizens should be spared; but the articles of capitulation were perfidiously violated, and two thousand of the soldiers and inhabitants were massacred in cold blood. In 1577, it was finally united with the States.

Haerlem is a large and handsome town, well built, and well paved. Its streets are broad and regular; and, like the other towns of Holland, it abounds in canals, bridges, and trees. The buildings most worthy of notice are the palace, the public library, and the church. The last is a very large structure, crowded, as is common in that country, with square wooden monuments, without any name, but having the arms of the deceased painted on a black ground, and the date of the death in gold letters. Its principal ornament is the organ, which is accounted the finest in the world, and which occupies the whole west end of the nave. It is supported by eight marble columns, between two of which in the centre is a noble emblematical alto-relievo, with figures as large as life. It was built in 1738, and has 8000 pipes, the largest of which is 32 feet in length, and 16 inches in diameter. There are 60 stops or voices, four separations, two shakes, two couplings, and twelve bellows. There is a pipe, which imitates the sound of the human voice, but it generally disappoints the expectations of strangers. The power and variety of tone possessed by this instrument is said to be truly astonishing. Some of its notes are so delicate as scarcely to exceed the warblings of a small singing bird; and others so loud, as to shake the massy pile in which it stands. "When the whole strength of the organ is exerted," says Mr Fell, "never did I hear, or could conceive, sounds more godlike. The swelling majesty of each gigantic note seems of more than mortal birth, and the slightest sounds enchant the ear. Solemnity, grandeur, delicacy, and harmony, are the characteristics of this noble instrument." It is played on two days of the week, for an hour each time; and the church is, on these occasions, the resort of the first company of the place. Haerlem is still more justly celebrated as the birth-place of Laurence Costar, who is said to have invented the art of printing, and the site of whose house is still pointed out to strangers by an inscription. He is said to have made the discovery by cutting the initial letters of his name upon a piece of bark, and using it as a seal; and specimens of the infancy of the art are preserved in the town-house. An academy of sciences was founded in 1752; and there is an elegant museum of natural history, formed by Dr Van Marum, superior to any other cabinet in Holland. The articles are in an excellent state of perservation, and arranged with scientific taste. The insects of the *Papilio* tribe are said to be particularly numerous, and many of them of the rarest description. There is an institution founded by Peter Teyler Vander Hulst, a rich merchant of Haerlem, who bequeathed the whole of his fortune for the improvement of knowledge, and the relief of the poor. Its annual revenues are said to have amounted, before the revolution, to the sum of 100,000 florins; but, instead of being applied to objects of science, they were allowed to accumulate, and are suspected to have been secretly appropriated, during the ascendancy of the French republic, to the urgent necessities of the state. The Stadthouse is a magnificent building at one end of the market-place, and contains a number of valuable paintings, among which is the first piece in oil, by Eyert, in 1437, which was sold during the siege in 1572 for a few stivers, and is now valued at 2000*l*. Haerlem is not a place of much trade; but is celebrated for its flourishing manufactures of velvets, damasks, fine linens, dimities, satins, worsted stuffs, ribbons, &c. which employ a number of workmen, and supply a profitable branch of traffic with Germany and Brabant. Its bleacheries, also, are famous for the delicate whiteness which they give to linen cloths, which has been attributed to a peculiar quality in the waters of the lake of Haerlem, incapable of imitation by any chemical process hitherto discovered. Great quantities of beer are exported to Friesland, &c.; and a gainful trade is carried on in flowers, one of which, a hyacinth, seen by M. Dutens in 1771, was valued by its owner at 10,000 florins. In the neighbourhood of the town are several handsome villas, and a wood of considerable extent full of delightful walks. About three miles distant is an extensive lake, called Haerlem Meer; sometimes, also, the Sea of Leyden, generally ten feet in depth, and containing a surface of fifteen square leagues. The population of Haerlem is 30,000. East Long. 4° 38′ 19″, North Lat. 52° 22′ 56″. See Trotter's *Memoirs of Fox;* Fell's *Tour in Holland;* Carr's *Tour in Holland;* and Owen's *Travels*, vol. i. (*q*)

HAGUE, a town in Holland, and the seat of the Dutch government, 10 miles south-south-west of Leyden, 14 south-west of Amsterdam, and about 3 from the coast. It is generally termed by geographers a village, because it has no municipal rights, and is not surrounded with walls; but it contains at least 38,000 inhabitants, and is one of the most elegant cities in Europe. It formed originally a part of the domains of the Counts of Holland, under the name of Graven Haag, Counts Hedge, which may perhaps account for its humble appellation of village. William II. Comte of Holland, removed his court from Gravesande to this place in 1250; from which time it has always been the seat of government, and in a political sense the metropolis of the United States. It stands in a drier soil, and a more elevated situation, than most other towns in Holland; and its atmosphere is therefore accounted more pure and healthful. The environs are delightful; and the approach to it extremely beautiful. The road, shaded on both sides by lofty rows of trees, is sufficiently broad to admit four or five carriages abreast, and so level, that not the smallest inequality of surface is to be perceived. On one side flows the canal covered with boats, and ornamented by numerous handsome villas on its banks; and directly in view of the traveller appear the lofty edifices of the Hague, with the beautiful forest scenery on the right of the town. The streets are generally spacious, and the meanest of them extremely clean. They are decorated with trees, canals, and tasteful bridges. They are paved with a kind of light-coloured bricks, which have a gay appearance, and which are so closely joined together, that no interstices can be perceived to harbour any species of dirt. The Voorhout, which is accounted the principal street, is about half a mile in length, with a mall in the middle, and contains a number of elegant buildings, in the purest style of architecture. But the Vyverburg is the most beautiful part of the city, and forms an oblong square, with a line of magnificent buildings on one side, and a large basin of water on the other. The palace of the Stadtholder consists chiefly of old buildings, erected at different periods, without any regularity of design, and is surrounded by a canal, with drawbridges. The French church is noted as being the burying-place of several Counts of Holland; and in its vicinity is a fine garden in imitation of that of Vauxhall. To the east and south of the town are many beautiful meadows and handsome country seats; and the trees are so disposed as to give the country the appearance of being better provided with wood than it is in reality. On the west side, leading to the fishing village of Scheveling, is a beautiful avenue, nearly two miles in length, and 20 paces in breadth. It runs in a perfectly straight line, and is shaded on each side by oaks, beeches, and limes of an astonishing size, so closely and skilfully planted, as to have the appearance of an impervious forest. The utmost care is taken to preserve this magnificent grove from injury; and cautions are fixed up at short distances, denouncing the severest penalties against offenders. On the north side, about a mile from the town, is a noble wood, about two English miles in length, and nearly one in breadth, and full of the finest walks and most pleasing views. The palace called Maison de Bois, a house of retirement for the Stadtholder, has nothing remarkable in its appearance or situation, but resembles the residence of a plain country gentleman. During the time of the Batavian republic, it was converted into a receptacle for the national cabinet of paintings; and, to the disgrace of the government, one suite of its apartments was occupied by the keeper of a tavern and brothel. The gardens belonging to this palace are kept with great care as a public promenade; but they are laid out in the worst taste. Every thing is unnatural and artificial, stagnant canals, puerile bridges, flower-beds of every conceivable form, and trees cut into the most fantastic shapes. One of the principal curiosities at the Hague was the prince's cabinet of natural history, and museum of rare productions, which contained an excellent selection of shells, insects, and birds, besides a great variety of toys from the East Indies. It had been removed to Paris; but is now probably restored along with the other pillaged property of the nation. The only species of trade of any consequence carried on at the Hague, consisted in the publication of continental productions, particularly of French books; but this literary traffic was completely extinguished by the revolution; and from the absence of the court, the city was falling rapidly into decay. By the recent restoration of the old government, its empty palaces have been re-occupied; and its former affluence and splendour may be expected to return. East Long. 4° 18′ 47″, North Lat. 52° 4′ 50″. See Trotter's *Memoirs of Fox*; Fell's *Tour in Holland*; Owen's *Travels*, vol. i.; and Sir J. Carr's *Travels in Holland*. (*q*)

HALBERSTADT, is an ancient town of Prussia, and capital of the principality of the same name. It is situated in the circle of Lower Saxony, on the small river Holtzemme. The principal public edifices and curiosities are, the cathedral, from the summit of which there is a fine view of the town, the court of St Peter's, the church of Notre Dame, and its organ. The palace now forms the town-house and excise-offices. There is here a literary society, which has published several journals of merit; and there are excellent libraries belonging to the cathedral, to the church of Sta Maria, the church of St Martin, and that of the Franciscans. The cathedral library contains a manuscript of Priscian upon parchment, and several annotations in the handwriting of Luther. The Temple of the Muses, belonging to M. Gleim, one of the celebrated German poets, is worthy of being visited. The principal manufactures of this town are those of woollen and linen goods, gloves and pipes, paper and wax. There is here also a work in which cobalt is prepared. The mountains of Spiegelberge, about half a league from this town, are deserving the notice of travellers. They have been laid out in the English style of landscape-gardening, by the late Baron Spiegel. The village of Stropke, about $1\frac{1}{2}$ leagues from Halberstadt, is celebrated for the skill with which its peasantry play at chess. Halberstadt was burned in 1179 by Henry the Lion, and a remarkable diet was held there by Lotharius II. in 1134. In 1203, it was surrounded by walls and ditches. By the treaty of Tilsit it was annexed to the kingdom of Westphalia; but we believe that it has now reverted to the Prussian monarchy. Breyhahn, the supposed inventor of beer, was born in this town; and his house, containing an inscription in honour of him, is still shewn. The population, which now amounts to 11,700, is composed equally of Catholics and Calvinists. East Longitude 11° 3′ 33″, North Latitude 51° 53′ 55″.

HALES, STEPHEN. See BOTANY, p. 30.

HALF-NOTE, *Elementary*, in music, according to several writers, has the ratio $\frac{15}{16}$, $=57\Sigma+f+5m$, and is the SEMITONE-*major*, which see.

HALF-NOTE, *Finger-key*, or artificial, is of very different magnitudes in the different modes of tuning, and places in the scales of keyed instruments. The number of f's in our notation, of any musical interval (by Σ, f and m), shews its number of these half-notes; and is fully explained in our article FINGER-KEY *Intervals*.

HALF-NOTE, *Greater*, of Holden, has the ratio $\frac{15}{16}$, $=57\Sigma+f+5m$. See SEMITONE *Major*.

HALF-NOTE, *Isotonic* or mean, is $\frac{1}{12}$th of the octave, $=1\div\sqrt[12]{2}$, $=51\Sigma+f+4\frac{5}{12}m$, or $51.003276\Sigma+f+4m$. See MEAN SEMITONE.

HALF-NOTE, *Lesser*, of Holden, has the ratio $\frac{24}{25}$, $=36\Sigma+f+3m$. See SEMITONE MINOR.

HALF-QUARTER *Tone*, of the Diacomatic genus, according to Feytou, is $\frac{1}{8}$ T, $=13\Sigma+\frac{1}{4}f+1\frac{1}{8}m$, $=13.038398\Sigma+m$, its common log. being .9936059,3469. Mr Hoyle and others call this interval a *comma*.

HALF-STOPS *on the Organ*, are those ranges of pipes which do not go through the whole compass of the instrument, from the treble to the bass; as the *cornet* and the *sesquialtera* stops, the *dulciana*, *basoon*, &c. stops.

HALF-TONE of the ancients, had the ratio $\frac{243}{256}$, $=46\Sigma+f+4m$; which is now called the LIMMA. See that article.

HALF-TONE *of Brougham*, has the ratio $\frac{11}{12}$, $=76.897955\Sigma+f+7m$; its common log. $=.9616713,1976$, and it is the hemitone major of Ptolemy's *chromaticum intensum*.

HALF-TONE, *Chromatic Tonicum*, is $\frac{1}{2}$T, $=2\sqrt{2}\div3$, $=52\Sigma+f+4\frac{1}{2}m$, $=52.0039312\Sigma\times f+4m$; its common log. $=.9744237,3877$, $=084962\times\text{VIII}$, $=4.74070\times\text{C}$, $=\frac{1}{2}\text{VIII}+\Sigma+\frac{1}{12}m$. It is the hemitone of the soft diatonic, and the chromatic diesis of Hoyle.

HALF-TONE, *mean*, of Sauveur, is $\frac{1}{12}$VIII, $=1\div\sqrt[12]{2}$, $=51.003276\Sigma+f+4m$. See *Mean* SEMITONE.

HALF-TONE, *mean*, of Dr Smith, is $\frac{1}{4}$III, $=\sqrt{2}\div\sqrt[4]{5}$, $=49\frac{1}{4}\Sigma+f+4\frac{1}{4}m$, $=49.251966\Sigma+f+4m$; its common log. $=9757724,9675$, $=.080482\times\text{VIII}$, $=4.490705\times\text{C}$: it is sometimes called the mean half note.

HALIFAX, is a populous market town of England, in the west riding of Yorkshire. It is situated on the western slope of a gentle eminence, washed by a branch of the river Calder, and is surrounded on all sides with high hills. The town is about three quarters of a mile long from west to east, but it is narrow and irregular in its breadth. The houses are in general neat and well built, and the town has a singularly variegated appearance, from the mixture of brick and stone buildings, and from the great number of small inclosures surrounded with stone walls. The church, which is a large Gothic structure, stands near the east end of the town. It is 64 yards long, and 20 broad, and is supposed to have been built in the reign of Henry I. The tower of the church, which is well proportioned, is said to be 117 feet high. Within the church are two chapels, one on the north, and the other on the south side. This church having been found too small, an elegant and spacious new church has lately been erected. The cloth hall, or piece hall, erected for the convenience of the manufacturers, is a large and elegant edifice of freestone, in the form of an oblong square. It covers an area of 10,000 square yards, and has 315 separate rooms for the reception of goods. It is generally open from 10 to 12 o'clock, and goods to the amount of 50,000*l.* are often exposed to sale at a time.

The parish of Halifax is one of the largest in England. It covers a space of 150 square miles, and has 13 chapels. It contains no fewer than 26 villages, whose united population, according to the census of 1811, is 73,515. The chief manufactures carried on in the parish are, those of shalloons unpressed, and dyed of a scarlet colour, which are sent to Turkey and the Levant; tammies, duroys, calamancoes, everlastings, russets, figured and flowered armines, says, moreens, and shags, kerseys, half thicks, serges, houlies, baize, broad and narrow cloths, coatings, and carpets. Several cotton manufactories have also been erected here. The trade of this town is greatly facilitated by a navigation from Sowerby bridge, in the neighbourhood of the town, along the Calder, to Hull, and will receive additional advantages from the Rochdale canal, which will connect the Calder at Sowerby bridge with the Bridgewater canal at Manchester. Excellent wool cards are also manufactured here. Great quantities of the freestone found in the neighbourhood are sent to London.

Gough, in his additions to Camden, informs us, "that the inhabitants within Hardwicke forest claimed a right or custom from time immemorial, that if a felon be taken with goods to the amount of 13½d. stolen within their liberty, after being carried before the lords bailiff, and tried by four frith-burghers, from four towns within the said precinct, he was, on condemnation, to be executed on the next market-day, after having been set in the stocks first; and after his execution, a coroner was to take the verdict of a jury, and sometimes of those who condemned him." The instrument used in these executions was one exactly the same as the modern guillotine, which was freely used against the robber of tenter grounds: (See Guillotine.) The last execution under the "Halifax gibbet law," as it has been called, took place in 1650. The bailiff was afterwards threatened with prosecution, if he should repeat them. According to the census of 1811, the township of Halifax contains.

| | |

| Do. employed in agriculture | 8 |
| Do. in trade and manufactures | 2261 |
| Males | 4151 |
| Females | 5008 |
| Total population | 9159 |

See *Beauties of England and Wales*, vol. xvi. p. 742.

HALIFAX, is the principal town of the county of the same name in Novia Scotia, one of the British possessions in North America. It is situated on the Bay of Chebucto, which is very spacious, and is able to contain, in perfect security, 1000 of the largest vessels. The town, which is about two miles long, and one-fourth of a mile broad, is situated on the west side of the harbour, on the declivity of a commanding eminence, elevated 236 feet above the level of the sea. In consequence of the streets intersecting each other at right angles, the houses are arranged into oblong squares. The Royal Naval Yard, supplied with military stores of all kinds, stands at the north end of the town. The accessible nature of the harbour, and its proximity to the principal interior settlements of the province, render it the fittest place in British America for a seat of government. Halifax is entrenched with forts of timber. The country around the town is rocky, and the soil unfit for cultivation. The imports of Great Britain, alone, into the single port of Halifax, amounted in 1810, to 600,000*l.* In 1790 and 1791, the whale fishery from the port of Halifax employed 28 sail of ships and brigs from 60 to 200 tons burthen. The principal exports from Halifax are the fish caught upon its coasts, great quantities of which are sent to the West India Islands. The amount of tonnage employed in the trade to and from the West India islands, and entered at the custom-house of Halifax, was, in 1792, 6489½ tons outwards, and 6571,1-4 tons inwards. Roads are opened from Halifax to all the settlements in the province. Population, 1000 houses, and 8000 inhabitants. Some accounts state the population so high as 15,000 or 16,000. West Long. 63° 35′ 45″, North Lat. 44° 44′. See Morse's *Geography*; Raynal's *History of the East and West Indies*; Gray's *Letters from Canada and* Nova Scotia.

HALIOTIS. See Conchology.

HALLE, is a town of Prussia, in the duchy of Magdeburg. It is situated on an agreeable plain on the river Saale. This town is divided into four quarters, and contains three Lutheran churches, and also places of worship for the Calvinists and the Roman Catholics, and a synagogue for the Jews. The principal edifices and curiosities of the town are, the cathedral; the red tower, which rises 268 Rhenish feet; the church of St Ulrice, where there is a fine monument erected to the celebrated Bulle d'Or of the Emperor Frederick II.; the orphans, physician Hoffman; the hotel de ville, which contains the hospital; the amphitheatre of anatomy, situated in the place d'Armes; the public library; the ruins of the chateau of Giebichenstein, from one of the windows of which the Landgrave of Thuringia threw himself, and received the title of the Leaper; and the ruins of the chateau of Moritzbourg. The orphans' hospital was built in 1698 by professor Franke, and contains a collection of artificial and natural curiosities, and a library. The university of Halle, formed out of a military academy, was established in 1699. It has a good library, and a cabinet of natural history. In the year 1802, it had 634 students. This town owes its celebrity to the fine salt springs in its neighbourhood. There are four of these which are very productive, lying on the Saale, in the lower part of the town, called the Vale of Saale. These salt springs furnish water, of which from 16 to 20 ounces yield from 3 to 3½ ounces of salt. They give work to 111 boiling houses. Each of these produces annually about 1200. The possessors of these springs are called Pfaenner, and the workmen Hallores. They are the descendants of the ancient Wends, and still retain their dress and manners.

Canstein's printing-office for the Bible is a very large establishment. In 1800, the number of copies printed amounted to 1,793,534 Bibles, exclusive of 877,999 copies of the New Testament, 1600 Psalms, and 52,500 copies of Jesus Sirach. The other articles of manufacture are, worsted and silk stockings, starch, flannels, buttons, linen, tobacco pipes, china ware, ribbons, and red and yellow Turkey leather. Population 20,000, including 1195 Halleres, or manufacturers of salt. East Long. 11° 58′ 2″, North Lat. 51° 29′ 5″.

HALLER, Albert de, a physician and professor of the last century, celebrated for the excellence and voluminousness of his writings. He was born at Berne, in Switzerland, on the 18th of October 1708. His father was Emmanuel Haller, advocate and chancellor of the county of Baden. His early education was committed to one Abraham Baillodz, a fanatical and severe preceptor, not well qualified for training with advantage a mind of Haller's sensibility. Yet he very early discovered an unparalleled assiduity in the pursuit of knowledge. At five years of age, having already learned to write, he arranged for himself, in alphabetical order, all the words that were taught him. In a little after, he compiled dictionaries in the Hebrew, Chaldee, and Greek languages, to which he often had recourse in his advanced years. At the age of ten, he composed German and Latin verses, the merit of which astonished his teachers. He ridiculed, in a Latin satirical poem, the pedantry of his private tutor, from whose severity he had suffered. At the age of twelve, he extracted from the dictionaries of Moreri and Bayle, 2000 articles of biography of the most celebrated men. When he was thirteen he lost his father, whose death left him in a great measure destitute of the resources of fortune. Being intended for the church, he finished his studies at the public school. On one occasion, having got a passage to translate into Latin, he attracted the admiration of the professors, by giving a translation of it into excellent Greek. Having finished his literary studies at the age of fourteen, he was led, by his ardour for learning, to pay a visit to Dr Newhams, an able physician at Bienne, whose son was one of his school companions. This gentleman gave him some instructions in the Cartesian system of natural philosophy. That pursuit, however, did not engross his whole attention. He continued to cultivate polite literature, and to exercise his talent in composing verses. The house in which he lived at Bienne having caught fire, he had only time to save his poems before it was burnt down. These poems he revised in less than twelve months after; and, reflecting on the satirical strain in which they were written, he committed them to the flames, with the exception of a few, which were left to attest his poetical talent, without reproaching the goodness of his heart.

After indicating talents which qualified him for making a conspicuous figure in any pursuit, he embraced the medical profession. Towards the end of the year 1723, he began his professional studies at Tubingen, under Camerarius and Duvernois, at that time celebrated teachers of anatomy and medicine. While at Tubingen, he occasionally joined in the convivial parties of his fellow-students; but was on one occasion so powerfully shocked by the abandonment of reason exhibited in these indulgences, that he formed a resolution, which he kept for the remainder of his life, to leave off entirely the use of wine. As Boerhaave's *Institutions* were used as a medical text-book at Tubingen, Haller had an opportunity of appreciating the genius of this author, which induced him to repair to Leyden to profit by his lectures. These two great men, having met in this manner, immediately perceived each other's merits. Boerhaave was then teacher of medicine and botany, and Albinus demonstrator of anatomy at that celebrated school. Both of these professors treated him with great distinction, and excited in his mind a powerful emulation. The superb museum of Ruysch, at Amsterdam, which he often visited, contributed at this time to animate and guide his studies. At the age of 19, he took the degree of Doctor of Medicine at Leyden. The subject of his thesis was one which he had discussed with Duvernois at Tubingen, the refutation of a position advanced by Professor Coschwitz, of Halle, that there were two salivary ducts in the posterior part of the tongue, which this author claimed as his discovery. Haller shewed that these supposed ducts were two veins. His works contain the plates by which this point was elucidated.

In 1727, he visited England, where he became intimately acquainted with Sir Hans Sloane, the president of the Royal Society, and Douglas and Cheselden, two of its distinguished members. He also spent some time at Oxford. He went next to France, where he formed an acquaintance with Geoffroy, Antoine and Bernard de Jussieu, Petit, and Ledran, and attended the lectures of the celebrated Winslow. A person who lived in an adjoining house having found him engaged in private dissection, denounced him to the minister of police, in consequence of which he was obliged to remain for some time in concealment. Dissections must have been conducted in that city with much greater difficulty than they are now. Paris has furnished for some time the amplest field in the world for this mode of pursuing professional knowledge: and, however much some may affect to connect this fact with the careless licentiousness of the French nation, it exhibits a bright contrast to the feelings so prevalent in our own country relative to the remains of the deceased. Like all the prejudices of savage ignorance, these feelings appear to the persons who cherish them sacred and refined, though they senselessly oppose an obstinate barrier to the dissemination of the most important knowledge.

Haller went next to Basle, where he applied himself to the study of geometry under the celebrated Bernoulli, and for a short time he filled, with great credit, the anatomical chair during a temporary illness of Professor Mieg. He returned to Berne in 1729, to practise as a physician. Those who were previously established there, detracted from his professional character, by representing him as blindly attached to delusive theories, and had even the address to prevent him from obtaining the appointment of physician to an hospital, for which, in 1734, he was a candidate. Two years after, however, he succeeded in that object, and discharged the duties of the office with great credit.

The celebrity of his talents for anatomy induced the republic of Berne to form an anatomical theatre, and appoint him their professor. About this time he cultivated various elegant studies. He pronounced an oration before a public litterary assembly, in which he asserted the general superiority of the ancients to the moderns. He published a collection of German odes and poetical epistles, which evinced the refined taste and delicate sensibility of the author, were admired in every part of Europe, and soon translated into various languages. The piece which gave greatest satisfaction was one devoted to a descriptive account of the Alps, and the manners of their inhabitants. Possessing, among his other accomplishments, an extensive acquaintance with biography and civil history, he received the charge of the public library at Berne. He drew up a *catalogue raisonnée* of the books, and arranged, in luminous order, a collection of more than 5000 medals belonging to it.

In 1736, he was invited, by the regency of Hanover, to fill the chair of anatomy, surgery, and botany, in the University of Gottingen, now for the first time instituted. He embraced this opportunity of devoting himself with more decided advantages to the improvement of science. He celebrated, in an ode, the inauguration of that university, and gave a competent share of praise to George II. King of Britain, for the zeal with which he promoted science in every part of his dominions. These included the American colonies, which were then illuminated by the genius of Franklin. At his entrance on his official duties at Gottingen, Haller was subjected to domestic discouragements of a trying nature. The carriage in which his wife and three children travelled from their native country to this new situation was overset on the road, and his wife received an injury, of which she died soon after arriving at the end of her journey. He applied himself, however, with great zeal, to his academical duties, encouragd by the increasing esteem of his colleagues, and by the assistance of his countryman Huber. He published, in 1739, his *Lectures on Boerhave's Institutions*, on which he had annually commented to his pupils. In this work, we find some germs of those more extended undertakings in physiology, which laid the foundation for so great a share of his future fame.

Having, among his other pursuits, cultivated that of botany, he published, in 1742, his *Enumeratio Stirpium Helveticarum*, in two folio volumes, which were embellished with numerous elegant engravings. The arrangement of this work rather presents us with a view of the gradations which take place in the external characters of plants, than a distribution fitted for permanent reference. Differences of opinion have even been entertained on the number of classes which Haller admitted, some reckoning them 13, others 15. In the following year, he published a systematic account of the plants in the botanic garden of Gottingen, which was republished nine years after in a more complete state, and contained a description of some new species. In 1749, he published, in one work, a collection of insulated remarks in botany, which he entitled *Opuscula Botanica*. Haller's great merit consisted in the versatility of his genius, which enabled him to pass rapidly from one subject to another, excelling equally in all. From the year 1743 to 1753, he published annually a fasciculus of anatomical plates of the most remarkable dissections which occurred in the course of his labours. These were admired for the minute explanations and learned notes which accompanied them.

In 1745, he published an ingenious argumentative discourse, *De Fœtibus Monstruosis*, in which he maintained that the original germs were in such instances defective, in opposition to the opinion that monstrosity was the effect of a derangement in the evolution of a germ originally perfect.

In 1746, he announced his experiments on respiration, in which he established the identity of office of the two layers of intercostal muscles, and the whole of the doctrines regarding the mechanical part of that function which have ever since been maintained, in opposition to the vague and erroneous notions which previously prevailed.

Haller, like most other eminent men of the medical profession, was engaged in some warm disputes. Dr Hamberger, Van Swieten, De Haen, Albinus, and Lamettrie, were his antagonists. In these, however, he generally displayed moderation. In the second edition of his *Essay on Respiration*, instead of accumulating rejoinders, and exposing afresh the weakness of the arguments of Hamberger, he suppressed every harsh expression which the first edition contained. He had some physiological discussions with Dr Whytt of Edinburgh, Lamure, Lecat, and Lorry, in the course of which candour and mutual respect were on all sides observed.

The subject on which he displayed greatest originality was irritability, which he considered as a property of animated bodies distinct from sensibility, and residing in different organs. On this subject, Dr Whytt of Edinburgh maintained with him a learned and instructive controversy. The latter undoubtedly had the superiority in argument, without prejudice to the genius which Haller displayed in the developement of his theory, and the command of temper with which he conducted the controversy.

In 1649, he published his *Primæ lineæ Physiologiæ*. This work maintained the pre-eminence as a text-book in this department long after a multitude of improvements had been made in the science. In the composition of it he did not indulge in theory, but exhibited facts with a rigorous exactness. He published new editions of various works in medicine, as well as in natural science. It is in the prefaces to these works and to his own that he communicates knowledge in the most striking and engaging manner. They are collected in one volume, entitled *German Opuscula*.

Betwixt the years 1747 and 1756, he was employed in publishing a collection of dissertations, composed by various authors, on anatomy in eight volumes, on surgery in five, and on the practice of medicine in seven.

Besides the works now mentioned, Haller published various physiological dissertations betwixt the years 1736 and 1753, which were of themselves sufficient to confer on him a high degree of celebrity. Among these, was one on the circulation by which the substance of the heart is supplied with blood for its own nutrition; one on the form of the Eustachian valve at different periods of life; and one on the *membrana decidua* of the fœtus.

At Gottingen, he exerted himself in the formation of various useful institutions; such as the College of Surgeons, the Gottingen Society, a lying-in hospital subservient to the obstetrical branch of education, an anatomical museum, and a seminary for instructing artists in painting objects of anatomy, botany, and natural history.

These exertions procured for M. de Haller a high degree of honourable fame. He was elected member of almost all the academies of Europe. It deserves to be mentioned, that the Academy of Upsal had the honour of taking the lead. A learned society, which shews no tendency to precipitate admiration, deserves great credit when it early distinguishes the buds of a just celebrity, and by its notice cherishes exertions which might otherwise in some measure languish. When on a visit to Berne, he was elected a member of the sovereign council of that republic.

George II. took a lively interest in the splendid success of Haller. In 1739, he appointed him his first physician as elector of Hanover; he gave him the title of aulic counsellor; and in 1749, procured for him letters of nobility from the Emperor of Germany, creating him baron. Haller always, however, declined the title.

More than one seminary of learning aspired to the honour of numbering him among their teachers. Dillenius, professor of botany at Oxford, having before his death, which happened in 1747, expressed a desire that he should be chosen his successor, an invitation was given him to fill that vacancy. The following year he was invited to succeed Albinus at Utrecht as chancellor to the university; and soon after, the King of Prussia offered him an eligible establishment at Berlin, with the presidentship of the Academy. But Haller did not so far indulge a roving ambition, as to accept of any of these honourable appointments. He thus testified a grateful attachment to that university, the founder of which was the earliest to give him the honours best suited to gratify his wishes, and to afford scope for the full exercise of his great talents. He determined not to leave Gottingen for any place except his native country.

In 1753, finding his strength unequal to the labours of his situation, conjoined with the execution of the plans of writing which he meditated, he resolved to return to Berne, to pass the remainder of his life. The seventeen years which he had spent at Gottingen, though brilliant in the eyes of Europe, and attended with much gratification to his own mind, were also marked with traces of affecting domestic vicissitudes. Two years after he had lost his wife in the manner already related, he married a second, who died a few months after marriage. He then married a third, who was his companion for the rest of his days. For thus consoling himself twice, after the death of the individual bound to him by the closest ties, he was subjected, as usually happens, to the censure of weak and vain persons, who affect a character for sensibility, because their taste leads them to admire consistency in unhappiness in an object to which, with the eyes of critical amateurs, they occasionally turn their attention, and who demand, for the gratification of that preposterous selfishness, that the most worthy characters should be involved in permanent bitterness, bereft at once of self-command and consolation. Haller was not chargeable with that harsh apathy of which the ancient Stoics are sometimes accused. He allowed the tides of sensibility on proper occasions to overflow; but, with the most rational of that sect, he set bounds to this indulgence; considering protracted tears as equally unbecoming with inordinate laughter. In an elegant poem, entitled *Doris*, he expressed the tenderest attachment to his first wife, and his sincere grief after her decease. In another monody within three years, he celebrated his second; and with the third, he spent many years in the enjoyment of the most respectable state of domestic happiness.

On his return to Berne, he was received by his countrymen with genuine affection and delight. He had the fortune to obtain the honourable situation of governor of the town-house, which was awarded by lot.

In a year after his return, he published his *Opuscula Pathologica*, a work containing some curious facts in morbid anatomy. It contained also a description of a singular epidemic which had appeared in Switzerland, a sort of bilious pleurisy, in which venesection was unfavourable. He made experiments on the medical power of electricity in deafness, a subject which then excited much attention in Europe, and he pronounced it wholly ineffectual. He sometimes made botanical excursions, sometimes dissected animals, and published ingenious accounts of such physiological results as he obtained; for example, the growth of the bones, the structure of the brain and eyes of fishes, the anatomy of the chick *in ovo*, and the general subject of generation. One of his conclusions on this last subject was, that the female has by far the greatest share in the production of the fœtus.

The most complete work of Haller, and that which will always be most perused, was his great System of Physiology in eight quarto volumes, which he began in 1757 and finished in 1766. This work contains a complete account of all the facts then known on this extensive subject, minute anatomical descriptions of the structure of the organs, and a detail of the systematic opinions of former authors. By this work he for ever rescued physiology from the degradation of being the sport of vain hypothesis: he divested it of the spurious riches with which fancy had decorated it, and in their stead exhibited a collection of facts, which was at once solid and extensive, and led the way for the accumulation of further results of observation and experiment, from which just theories might gradually arise.

In 1772, 1773, and 1774, he amused himself by publishing, in the form of three romances, his thoughts on the degrees of happiness to be enjoyed under different forms of political government. In the first, entitled *Usong*, he delineated the happiness arising from the administration of a virtuous and judicious despotic monarch, who encourages justice and morality. In the second, *Alfred*, he represented that of a limited monarchy, in which the nobles and people preserve their right to a share in the management of the public interests; and the king, while he regulates the state, pays respect to established forms, consults systematically the public voice, and exerts himself to maintain that constitution by which his own power is at once prevented from becoming lawless, and assisted in the dispensation of national benefits. In the third, entitled *Fabius and Cato*, he described a well-regulated aristocracy. Where it is dangerous to insist on the desirableness of a complete change of government, it is wise to endeavour to stimulate to virtue those in whose power the destinies of the human race are placed. At the same time it is a beneficial exercise of a philosophical talent to speculate on the most eligible forms for those communities which have as yet no established government, or for those eras of revolution in which the persons qualified to judge of what is best, and possessed of power by their union to adopt it, are perfectly disposed to embrace such institutions as would contribute most effectually to the perpetual welfare of society. On this speculation Haller did not enter farther, than by shewing himself partial to an aristocracy like that of his native country; nor did he so far complete his plan, as to paint the advantages of the best state of a democracy.

Haller drew up several articles for the French Encyclopedie: and he long guarded the interests of general literature, by writing in the German review at Gottingen. The articles of which he was the author in that work amounted to 1500.

His last works were, his *Bibliotheca Botanices, Anatomicæ, Chirurgiæ et Medicinæ Practicæ*. In this extensive and well digested list of authors, he points out in the amplest manner, and with a luminous arrangement, the sources from which he derived his knowledge, and from which it might be obtained by others. It is written in the order of time, in subdivisions corresponding to the different epochs and schools of systematic opinion, and to each subdivision a short descriptive sketch of the period or sect in these sciences is prefixed. It thus exhibits an interesting history of the advances of science, accompanied by a full enumeration of the literary monuments which serve for the records of knowledge and opinion. His *Bibliotheca Medicinæ* was not completed. He had it also in view to form a similar work on Natural Philosophy.

The republic sometimes conferred on him temporary offices, which his philosophical talents enabled him to fulfil with distinguished advantage; and he was always ready to employ these talents for the public good. While he was governor of the canton of L'Aigle, he essentially benefited the resources of the state, by improving the manufacture of salt. He exerted himself for the establishment of a house for the maintenance and education of orphans and the children of decayed citizens, and also a school for the education of the children of the more opulent classes, in which the acquisition of useful knowledge was preferred to the objects of a scholastic discipline. By his influence, the situation of the clergy of the Pais de Vaud, which had been wretched and degrading, was rendered comfortable and respectable.

The university of Gottingen, and its patron the King of Britain, solicited him to return to that place, offering him the chancellorship on the death of Mosheim. The King of Prussia offered to make him chancellor of the University of Halle, and the Empress of Russia made tempting proposals to induce him to go to Petersburg. But he preferred remaining in the bosom of his native country, which at this time testified its respect for his character, and its desire of retaining him, by voting to him a competent annual salary. In 1776, he received the order of the Polar Star from the King of Sweden.

The Emperor of Germany, in the course of his last travels, visited Haller, and found him labouring under an accumulation of infirmities which he evidently could not long support. On his return to Vienna, he sent him some bottles of wine of uncommon excellence, with a quantity of the best bark; but Haller, before he had it in his power to set the due value on this simple tribute of private friendship from that monarch, had paid the debt of nature. The emperor received the news of his death with unfeigned grief; and afterwards, in order to secure an honourable relict, and a useful memorial of the studies of this great man, he purchased his library, and had it conveyed to Milan.

His disease was a form of retrocedent gout, affecting the region of the bladder, and was accompanied with so much inconvenience that he was obliged to confine himself at home. He published among the memoirs of the Society of Gottingen, an account of its progress, and of his personal experience of the effects of opium and other remedies. In the midst of this distressing illness, he published a second edition of his great work on physiology.

M. Rosselet, his physician, told him, at his own desire, his opinion of the exact time at which he was likely to die. In his last moments he was perfectly collected, and, with his hand on his pulse, coolly remarked to M. Rosselet that it had now ceased to beat.

He had eleven children, eight of whom he lived to see established, 20 grand-children, and before his death two great-grand-children. His eldest son, Gottlieb Emanuel, was afterwards an eminent citizen of Berne, and distinguished for his historical learning.

Haller was of the Protestant religion, and sincerely attached to his religious principles. La Mettrie, in dedicating to him a work in support of materialism, created in him the utmost horror and distress, by affecting to represent his discoveries as the most valuable proofs of this doctrine. His mode of life was rigidly sober. His only beverage was water, and he delighted to represent the unfitness of the climate of Berne for the culture of the grape as a signal advantage conferred by nature on his country.

Haller was exceeded by none of his contemporaries in the extent of his general information. He was well acquainted with most of the languages of Europe, and corresponded with the utmost facility with the literati of France, England, Italy, Holland, Denmark, and Sweden, in their respective native languages.

A more industrious literary life than that of Haller cannot be imagined. Every moment of his time was occupied. The reading of new books, and the composition of the lighter species of memoirs, and articles for reviews, were his only pastimes. During a long state of delicate health his bed was in his library, where he sometimes spent months without ever going out. There he eat his meals, and, with the society of his family and his books, he concentrated within this narrow space all that he held most dear on earth. He communicated to those around him a taste for scientific pursuits. His house was a sort of sanctuary of the sciences. He was assisted by his pupils, who had the range of his library and his theatre. His wife acquired the art of drawing and painting, for the purpose of rendering herself useful to him. His children, friends, and fellow citizens, all regarded it as their duty to contribute to his labours. His uncommon sensibility subjected him to quick alternations of pain and pleasure. He rarely joined in general social parties. When he did, he often rendered himself extremely agreeable; his conversation, however, was always that of a man of learning; even on trifling subjects, he displayed profound sense, and a spirit of application. He was above the ordinary size,—his eyes were lively,—and his countenance noble and expressive.

He was probably the most voluminous writer after Galen. His Latin style is sometimes dry, complicated, and not readily understood by persons unaccustomed to it: but the profundity of views, the well connected strain of reflection, and the great erudition with which his works are replete, never fail to reward the reader. Various as the subjects were which occupied his pen, he shews a consistency of doctrine, and a unity of views and of method, which characterise solidity of judgment, and announce a commanding genius. His works on medical science will long continue to be read with profit, when the labours of many others, which have attracted the notice of the day, are reduced, by the cool decision of posterity, to their just rank —that of being regarded as the errors of exuberant fancy, imposing on the age in which they appeared, by laying premature and peremptory claim to the credit of regular scientific systems. See Vicq d'Azyr's *Eloges;* Henry's *Life of Haller; and* Haller's *Bibliotheca Anatomiæ.* (H D.)

HALLEY, Edmund, a celebrated astronomer and natural philosopher, was born at Haggerston, in the parish of St Leonards, Shoreditch, London, on the 8th November 1656. His father, who was an opulent citizen and soapboiler, sent him to St Paul's school, where, under the care of the learned Dr Gale, he made rapid advances in his classical studies, and acquired such a taste for elementary astronomy, that he amused himself in making dials, and observed the change in the variation of the needle at London in the year 1672, the year before he left school. From this seminary, which he left in 1673, he went to Queen's College, Oxford, where he was entered a gentleman commoner, and where, with the aid of a good collection of instruments which his father had purchased for him, he devoted himself almost exclusively to the study of mathematics and astronomy. In the year 1676, he published his first paper in the Philosophical Transactions, entitled "*A Direct and Geometrical Method of investigating the Aphelia, the Eccentricities, and the Proportions of the Orbits of the Primary Planets, without supposing the equality of the Angle of Motion at the other focus of the Planet's Ellipsis;*" and he continued to employ himself in astronomical observations. Although he had long entertained a plan of forming a complete catalogue of the fixed stars, yet he abandoned this scheme upon hearing that Flamstead and Hevelius were occupied in the same pursuit. He resolved, however, to form a catalogue of the stars of the southern hemisphere; and, by the influence of Joseph Willamson, Secretary of State, and Sir J. Moore, Surveyor of the Ordinance, Charles II. was prevailed upon to send Halley to St Helena, in order to accomplish this desirable object. He arrived on the island in February 1677, after a voyage of three months; and though he was much interrupted by the frequent fogs which hover over it, yet, by the most unremitting industry, he at last executed his plan, which he published in 1679, under the title of *Catalogus Stellarum Australium.* This work was presented, on his return from St Helena, in November 1678, to Charles II. who gave him a mandamus to the University of Oxford for the degree of A.M. Halley had rewarded the kindness of his patron by forming a new constellation, under the name of *Robur Carolinum.* During his stay at St Helena, he had the good fortune to observe the transit of Mercury over the sun's disc.

In the year 1678, Halley was elected a Fellow of the Royal Society of London; and, in consequence of the dispute between Hevelius and Hooke respecting the use of telescopic sights, he went to Dantzic in 1679, for the purpose of settling the controversy, by examining the method of observation employed by the Polish astronomer. He remained at Dantzic from the 26th of May till the 18th July, and returned to England deeply impressed with a conviction of the wonderful perfection of Hevelius's instruments, and of the great accuracy of his observations.

In the year 1680, Halley set out for Paris, accompanied by his friend Mr Nelson, with the view of performing the grand tour of Europe. In crossing the English channel, he obtained a view of the great comet upon its return from the sun; and having been fortunate enough to observe its descent towards that luminary, he was able to complete his observations at the Royal Observatory of Paris, which was then under the direction of Dominique Cassini. From Paris he went to Italy, where he spent the greater part of the year 1681; but his private affairs obliged him to return to England about the end of the year.

Soon after his arrival in London, Halley married the daughter of Mr Tooke, auditor of the Exchequer, and took up his residence at Islington, where he put up his astronomical apparatus, and pursued with ardour his favourite study. With this amiable woman Halley lived 55 years, but was not blessed with any family.

In the Philosophical Transactions for 1683, he published his *Theory of the Variation of the Magnetical Compass*—a paper of singular merit, in which he endeavours to shew, that the "whole globe of the earth is one great magnet, having four magnetical poles or points of attraction, near each pole of the equator two; and that, in those parts of the world which lie near adjacent to any of these magnetic poles, the needle is governed thereby, the nearest pole being always predominant over the more remote."

Our author's studies were now somewhat interrupted by domestic misfortunes. His father had suffered greatly from the fire in London; and having imprudently entered into a second marriage, he was reduced comparatively to a state of poverty. His son, however, speedily resumed his usual occupations; and, in the year 1684, his attention was directed to the subject of Kepler's sesquialterate proportion, from which he concluded that the centripetal force must be inversely as the square of the distance. He found himself unable, however, to establish this by geometrical principles; and having applied in vain for assistance to Dr Hooke and Sir C. Wren, he at last made a visit to Cambridge, in order to consult Mr Newton. This illustrious mathematician communicated to Halley 12 theorems which he had written upon the subject, containing his theory of gravitation. Halley was so delighted with the developement of this great discovery, that he prevailed upon Newton to complete his *Principia*, which was actually published in 1686, under the immediate care of Dr Halley, who prefixed to it a discourse of his own, and complimented Newton in an elegant copy of Latin verses.

In the year 1685 Halley had been appointed clerk to the Royal Society, and was the principal person employed in the publication of its Transactions.

In 1686, he published a paper, entitled *An Historical Account of the Trade Winds and Monsoons, observable in the Seas between and near the Tropics*, with an attempt to assign their physical cause; and in 1687, appeared his *Estimate of the Quantity of Vapour raised out of the Sea by the warmth of the Sun*, which gave so much satisfaction to the Royal Society, that they requested him to pursue the subject. He accordingly published in 1691, his paper *On the Circulation of the Watery Vapours of the Sea, and the Origin of Springs*; in which he first pointed out that fine provision of nature, by which a constant circulation of water is kept up between the atmosphere and the ocean. Halley published in 1687, his paper *On the Numbers and Limits of the Roots of Cubic and Biquadratic Equations*. In 1688, he published a correct ephemeris for that year; and in 1691, appeared his paper *On the Time and Place of Julius Cæsar's Descent upon Great Britain*, in which he considers it as demonstrated that Cæsar landed in the Downs, a little to the northward of Dover cliffs, on the 26th of August, 55 before Christ. In consequence of having had the good fortune to observe the transit of Mercury when he was at St Helena, Halley directed his attention particularly to this class of phenomena; and in 1691, he published a paper *On the visible Conjunctions of the Inferior Planets with the Sun*, in which he has calculated all the transits of Mercury from A. D. 1605 to 1799, and all those of Venus from 918 to 2004. He was fully aware at this time of the great advantages which astronomy would derive from the observation of these phenomena; and he remarks, that "the principal use of these conjunctions is accurately to determine the distance of the sun from the earth, or his parallax, which astronomers have, by several methods, attempted in vain, while the smallness of the angles sought do easily elude the nicest instruments; but in observing the ingress of Venus into, and egress from, the sun, the space of time between the moments of the internal contacts may be obtained to a second of time, that is, to $\frac{1}{15}$ of a second, or 4‴ of the observed arch, by means of an ordinary telescope and clock that goes accurately for 6 or 8 hours." Halley had, however, been anticipated in this ingenious remark by our countryman James Gregory. See our life of JAMES GREGORY.

In consequence of Dr Bernard's resignation, a vacancy too place in the Savilian professorship of Astronomy at Oxford. Dr Halley was naturally considered as well qualified for the chair, and became one of the candidates. Dr David Gregory, however, was the successful competitor; and Halley is known to have lost the office solely from his adherence to the principles of infidelity. Mr Whiston informs us, "that Bishop Stillingfleet was desired to recommend him at court; but hearing that he was a sceptic and a banterer of religion, the Bishop scrupled to be concerned, till his chaplain, Bentley, should talk with him about it, which he did. But Halley was so sincere in his infidelity, that he would not so much as pretend to believe the Christian religion, though he thereby was likely to lose a professorship, which he did accordingly, and it was then given to Dr Gregory."

In 1692, Mr Halley resigned his situation as assistant-secretary to the Royal Society, and in 1696, when five different mints were established for the recoinage of the silver specie, he was made comptroller of the office at Chester. In 1692, Mr Halley published a singular paper *On the Cause of the Change of the Variation of the Magnetic Needle; with an Hypothesis of the Structure of the Internal Parts of the Earth*. In order to account for the change in the variation of the needle, he supposes that there is an interior globe within the earth, separated from the external sphere by a fluid medium; that they revolve about the same diurnal axis nearly in 24 hours, the outer sphere moving either a little slower or faster than the internal ball; that the magnetic poles, both of the external shell and the included globe, are distant from the poles of rotation; and that the variation arises from the change in the relative distances of the external and internal poles, in consequence of the difference of their daily revolutions. The whole of this paper, though marked by the ingenuity of its author, is characterised by an extravagance of speculation, in which he was not accustomed to indulge. He even goes so far as to say, that there may be several internal spheres separated by atmospheres, the concave side of each shell being made up of magnetical matter; and he considers it as by no means improbable, that these different spheres may be occupied by living beings. The concave arches," says he, "may, in several places, shine with such a substance as invests the surface of the sun; nor can we, without a boldness unbecoming a philosopher, adventure to assert the impossibility of peculiar luminaries below, of which we have no sort of idea."

Till the year 1698, Dr Halley continued to enrich the Philosophical Transactions with various memoirs on the price of annuities on lives; on the foci of lenses; on the roots of equations, and on different subjects in mathematics, meteorology, antiquities, astronomy, and optics. He now, however, conceived the design of making an extensive voyage, to determine the variation of the needle in different parts of the world. For this purpose, King William appointed him captain of the Paramour Pink, in which he set sail on the 20th of October 1698. Having sailed along the African coast, he crossed to the coast of America, going some degrees south of the line. His crew having begun to lose their health, and his officers to become mutinous, he proceeded to the West Indies to get them exchanged; and when he found this impracticable, he returned to England, where he arrived early in July 1699. When his lieutenant had been tried and cashiered, he again set sail on the 16th of September 1699, and after having made observations at St Helena, the Brazils, Cape Verd, Barbadoes, Madeira, Canaries, the Coast of Barbary, he proceeded in a southerly direction till he was stopped by the ice in the south latitude of 53°. Having thus accomplished the object of his voyage, he returned to Britain, and anchored in Long Reach on the 7th of September 1700. From this voyage he received the title of Captain in the Navy, and, through the influence of Queen Caroline, he enjoyed half pay during the remainder of his life. The results which Dr Halle obtained during this voyage were published in 1701 in his general chart, which exhibits the variation of the needle in all the seas frequented by navigators.*

In 1701, Mr Halley was sent by the King to observe the course of the tides in every part of the English Channel, and to ascertain the geographical positions of the principal headlands. This task was accomplished in 1702, and the results were published in a large chart of the English Channel.

The Emperor of Germany having resolved to form a commodious harbour in the Adriatic, Halley was sent by Queen Anne to inspect the two ports on the coast of Dalmatia. He set out on the 22d of November 1702, and went to Istria by the way of Holland and Germany; but, in consequence of the opposition which the Dutch made to the scheme, it was laid aside. The Emperor, however, when he saw him at Vienna, made him a present of a rich diamond ring from his own finger, and gave him a letter of recommendation written in his own hand to Queen Anne. No sooner had he returned to England, than he was a second time dispatched to Germany on the same errand. In passing through Hanover, he supped with the Electoral Prince, afterwards King George I. and his sister the Queen of Prussia; and after having been presented to the Emperor on the evening of the day on which he arrived at Vienna, he set out with the chief engineer for Istria, when the fortifications of Treiste were, by his advice, repaired and enlarged.

Upon his return to England in November 1703, he succeeded to the Savilian professorship of geometry at Oxford, which was vacant by the death of Dr Wallis; and the university at the same time conferred upon him the honorary title of doctor of laws. As soon as he settled in this new situation, he began, in conjunction with his colleague Dr Gregory, to publish the works of the ancient geometers, in pursuance of the plan recommended by Sir Henry Saville. He translated from the Arabic into Latin, *Apollonius de Sectione Rationis*; (See ANALYSIS. vol. i.) and he restored the two books of the same author, *De Sectione Spatii*, from the account given by Pappus. This work appeared in 1706. Dr Halley assisted also in preparing for the press, the Conics of Apollonius; and he supplied the whole of the 8th book which had been lost. This work appeared in 1710; and contained also Serenus *On the Section of the Cylinder and Cone*, which was printed from the original Greek, with a Latin translation. In 1708, Dr Halley published the *Miscellanea Curiosa*, in 3 vols. 8vo, which contained several original articles by himself.

On the death of Sir Hans Sloane in 1713, Dr Halley was appointed secretary of the Royal Society. In 1716, he published his paper *On the art of living under water*, which contains an account of his diving bell, and of the experiments which he made with it at great depths in the sea: (See DIVING BELL, vol. viii. p. 11, 12.) At the death of Mr Flamstead in 1719, Dr Halley was appointed astronomer royal; and though he had now reached the 64th year of his age, he entered upon the duties of his new office with a degree of juvenile ardour; and without the help of an assistant, he continued for 20 years to make celestial observations with the most surprising and unremitting assiduity. In the space of 9 years, a period of the moon's apogee, he made no fewer than 1500 observations on the moon's right ascension, the object of which was to determine the inequalities of her motion, and to furnish navigators with the most correct means of finding the longitude at sea. He gave an account of this plan in the *Phil. Trans.* for 1731, in his *Proposal for finding the Longitude at Sea within a Degree, or 20 Leagues.* In an appendix to the second edition of Street's Caroline Tables, Halley had suggested this method of finding the longitude so early as 1683 and 1684; and he now shews, from a comparison of the lunar tables with accurate observations, that the longitude may always be determined to within 20 leagues under the equator, and 15 leagues in the British Channel.

Dr Halley was constantly employed in perfecting his tables of the planets. They were drawn up in 1725; but he was unwilling to publish them till they were made as perfect as he could. In 1729, he was elected a foreign member of the Academy of Sciences at Paris. In 1737, he was seized with a paralytic affection in his right hand; but this did not prevent him from attending the Royal Society Club every Thursday. His disorder, however, gradually increased; and he died on the 14th January 1742, in the 86th year of his age. He was buried in the church-yard of Lee, near Blackheath. Dr Halley's *Tabulæ Astronomicæ* were published in 1749. They were for a long time the most complete and accurate; but they have long since been superseded by others more correct and valuable.

There are few individuals who have been so distinguished as Dr Halley, both for their industry and their genius. He was the author of no fewer than 78 papers in the *Philosophical Transactions*, upon almost every branch of natural philosophy; and a great number of these are remarkable for their originality, and for the new and ingenious views which they unfold. The name of Halley, however, is not associated in the history of science with any brilliant effort, or any striking discovery. His reputation was widely extended, both as a profound philosopher, and as a man of taste; and almost every department of physical science received some improvement from his labours. The upright character of Halley was strikingly displayed in his refusal to assume the mask of religion, when it would have conducted him to a professorship in Oxford. But while we admire this example of sincerity and disinterestedness in

* The original journals of Dr. Halley's two voyages were published by the late Alex. Dalrymple, Esq. in 1775, in a thin quarto volume.

his unbelief, we cannot but feel that a stain is left upon his reputation, when history records that he was a "banterer of religion." In an age when a philosopher like Newton was an open defender of Christianity, it was indelicate in a philosopher like Halley to assume in public the character of an infidel.

HALO, or CORONA, is a luminous circle, sometimes containing all the prismatic colours, which occasionally appear about the sun and moon, and other luminous bodies.

In the northern regions of the globe, the sun and moon frequently appear surrounded with halos, or coloured circles, having their diameter about 44° or 92°. When a horizontal white circle intersects these halos, *parhelia* or brighter spots appear near their intersections, and also portions of inverted arches of various curvatures. In the horizontal circle, there are often *anthelia* or bright spots nearly opposite to the sun.

In order to lay before our readers a pretty full account of this curious class of phenomena, we shall begin with describing the most interesting halos that have hitherto been observed, and then give an account of the theories which have been employed to explain them. As the most minute accuracy is necessary in the description of the phenemena, we shall generally give it in the words of the observers themselves.

On the 20th March 1629, Scheiner observed at Rome a singular halo, which Huygens describes in the following manner from the writings of Descartes and Gassendi:

"A is the place of the observer at Rome, B the vertex or point over his head, C the true sun, AB a vertical plane passing through the observer's eye, the true sun and the vertex B, which are all projected in the straight line ACB (Plate CCLXXXVII. Fig. 1.) About the sun C, there appeared two concentric rings not complete, but diversified with colours. The lesser and inner of them, DEF, was fuller and more perfect; and though it was open from D to F, yet these ends D and F were perpetually endeavouring to unite. Sometimes they did unite and complete the ring, and then opened again. The other exterior and fainter, and scarce discernible circle, was GKI; it had a variety of colours, but was very inconstant. The third circle KLMN was very large, and all over of a white colour, such as are often seen with paraselenæ about the moon. This was an eccentric circle passing through the middle of the sun, at first entire, but towards the end of the appearance it was weak and ragged, and scarce discernible from M towards N. In the common intersection of this circle, and of the outward iris GKI, there broke out two parhelia N and K, not entirely perfect; K was somewhat weak, bnt N shone brighter and stronger. The brightness in the middle of them both resembled that of the sun; but towards their edges, they were tinged with colours like those of the rainbow. They were not perfectly round and even at their edges, but uneven and ragged. The parhelion N was a little wavering, and sent out a spiked tail NP, of a colour somewhat fiery, which had a continual reciprocation. The parhelia at L and M, beyond the zenith B, were not so bright as the former, but rounder, and white like the circle which they were placed in. They resembled milk or clean silver. The parhelion M was almost quite extinct at half an hour past two o'clock, excepting that some faint remains would revive now and then, and the circle itself vanished in that place. The parhelion N disappeared before K did, and while M became fainter K grew brighter, and vanished last of all." This has been generally called the Roman Phenomenon.

On Sunday February 20th 1661, new style, Hevelius observed at Dantzic a very curious halo, which he thus describes in the appendix to his *Mercurius in Sole Visus*, page 174. "A little before 11 o'clock, the sun being towards the south, and the sky very clear, there appeared seven suns together in several circles, some white and some coloured, and these with very long tails, waving and pointing from the true sun, together with certain white arches crossing one another. 1st, The true sun at A (Fig. 2.) being about 25° high, was surrounded almost entirely by a circle whose diameter was 45°, and which was coloured like the rainbow with purple, red and yellow, its under limb being scarce $2\frac{1}{2}°$ above the horizon. 2d, On each side of the sun at B and C, towards the west and east, there appeared two mock suns, coloured especially towards the sun, with very long splendid tails of a whitish colour, and terminating in a point. 3d, A far greater circle YXHVZ, almost 90 degrees in diameter, encompassed the sun and the former lesser circle GBIC, and extended itself down to the horizon. It was very strongly coloured in its upper part, but was somewhat duller and fainter on each side. 4th At the tops of these two circles at G and H were two inverted arches, whose common centre lay in the zenith, and these were very bright and beautifully coloured. The diameter of the lower arch QGR was 90°, and that of the upper one THS was 45°. In the middle of the lower arch at G, where it coincided with the circle BGC, there appeared another mock sun; but its light and colours were dull and faintish. 5th, There appeared a circle BEFDC much bigger than the former, of an uniform whitish colour, parallel to the horizon at the distance of 25°, and 130° in diameter, which arose as it were from the collateral mock suns B and C, and passed through three other parhelia of an uniform whitish colour like silver: one at D, almost 90° from the true sun, towards the east; another at E, towards the west; and a third at F, in the north, diametrically opposite to the true sun, all of the same colour and brightness. There passed also two other white arches EN, DP, of the greatest circle of the sphere through the eastern and western mock suns E, D, and also through K, the pole of the ecliptic. They went down to the horizon at N and P, crossing the great white circle obliquely, so as to make a white cross at each parhelion; so that seven suns appeared very plain at the same time; and if I could have seen the phenomenon sooner from an eminence, I do not question but I should have found two more at H and I, which would have made nine in all; for there remained in those places such marks, as made this suspicion not improbable.

This most delightful and extraordinary sight lasted from 30 minutes past 10 to 51 minutes past 11; though it had not the same appearance all the while, but sometimes one and sometimes another. It appeared in the perfection of this description at about 11 o'clock, and then degenerated by degrees. The northern mock sun at F vanished first of all, together with a part of its circle; the other parhelia with their arches lasted till 10 minutes past 11, then the eastern mock-sun, and after that the western, vanished with both the crosses. Soon after this the collateral parhelia C, D suffered several changes; sometimes one was brighter than the other in light and colours; and sometimes fainter and darker. For at 18 minutes past 10 the eastern parhelion at C vanished, while the western parhelion at B remained very conspicuous; and 24 minutes past 11, the eastern one was very bright again, and remained so, while the western one disappeared at 40 minutes past 11; although this western one had almost always the longer tail. For the tip of it was frequently extended for 30 degrees, and sometimes 90, as far as the parhelion E; but the tail of the eastern one C was scarce above 20 degrees. At 30 minutes past 11, the great vertical circle YXHVZ was destroyed; but the inverted arches H and G, together with the collateral parhelia B and C, continued to the last.

The scheme of this phenomenon is drawn in the same manner as the constellations are drawn upon an artificial globe, to be received by the eye on the outside of it. For by this means every thing is represented much clearer and distincter. Nevertheless, the place of the observer was nearly under the zenith, within the circle parallel to the horizon; so that the true sun appeared to him in the meridian, the mock sun F in the north, and the other two at D and E on each hand. But if you desire to have this extraordinary phenomenon represented a little plainer: upon an artificial globe, whose pole is elevated to our altitude at Dantzic, with the centre A in the 2d degree of Pisces, where the sun then was, and with a semi-diameter of $22\frac{1}{2}$ degrees, describe the circle GBIC; 2d, and then the circle YXHVZ with a radius of 45 degrees; 3d, and with the same centre and semi-diameter of 90 degrees, draw the circle NEKDP through the two white mock suns, E, D; 4th, and with a semi-diameter of $22\frac{1}{2}$, the zenith being the centre, draw the arch THS; 5th, and also the arch QGR, with a radius of 90 degrees, upon the same centre; 6th, and lastly, the circle BEFDC, parallel to the horizon, with a radius of 90 degrees. And the draught being finished in this manner will appear very beautiful and harmonious."

On the 2d January 1586, Christopher Rothman observed at Cassel another halo, which he describes in the following manner, in his description of a comet seen in that year. "The sky being very clear in the east just before sunrise, there appeared an upright column, exactly situated in a vertical circle. Its breadth was every where equal to the sun's diameter; and it looked as if some village was on fire beyond the mountains. For it appeared like a column of flame, excepting that its thickness was every where the same.

Soon after, in the same column, there arose an image of the sun, exactly resembling the true sun. There was scarce one digit of this image under the horizon when the true sun began to rise in the same column, which was followed in like manner by another image. The column, with its three suns touching one another, continued always upright, or in a vertical circle, as appeared by the plummet of a quadrant.

These suns had all the same appearance, except that the true sun in the middle was brighter than the rest. This appearance of the column passing through three suns lasted almost a quarter of an hour, till they were covered by a black cloud descending from above.

Scheiner observed, in 1630, the halo represented in Fig. 3, which is thus described by Gassendi: "The diameter of the corona MQNE next to the sun, was about 45 degrees; and that of the remoter corona ORP, was about 95° 20′; they were coloured like the primary rain-bow, but the red was next the sun, and the other colours in the usual order. The breadths of all the arches were equal to one another, and about a third part less than the diameter of the sun, as represented in the scheme. Though I cannot say but the whitish circle OGP parallel to the horizon, was rather broader than the rest. The two parhelia, M N, were lively enough; but the other two at O and P were not so brisk; M and N had a purple redness next the sun, and were white in the opposite parts; O and P were all over white. They all differed in their durations. For P, which shone but seldom and but faintly, vanished first of all, being covered by a collection of pretty thick clouds. The parhelion O continued constant for a great while, though it was but faint. The two lateral parhelia M and N were seen constantly for three hours together: M was in a languishing state, and died first, after several struggles; but N continued an hour after at least. Though I did not see the last end of it, yet I was sure it was the only one that accompanied the true sun for a long time, having escaped those clouds and vapours which extinguished the rest. However it vanished at last upon the fall of some small showers. This phenomenon was observed to last four hours and a half at least; and since it appeared in perfection when I first saw it, I am persuaded its whole duration might be above five hours.

The parhelia Q R, were situated in a vertical plane passing through the eye at F, and the sun at G, in which vertical the arches CRH, ORP either crossed or touched one another. These parhelia were sometimes brighter, sometimes fainter than the rest; but were not so perfect in their shape and whitish colour. They varied their magnitudes and colours, according to the different temperature of the sun's light at G, and the matter that received it at Q and R, and therefore their light and colours were almost always fluctuating, and continued as it were in a perpetual conflict. I took particular notice that they appeared almost the first and the last of all the parhelia, excepting that at N.

The altitude of Q above the horizon in the morning, at the beginning of the observation, was 49° 40′; that of R was 76° 10′; that of the true sun was 28° 30′; hence the height of Q above the sun was 21° 10′, and the height of R above the sun was 47° 40′.

"There was a north wind at the beginning of these observations, but by degrees it changed to the east, and at last to the south; yet it brought no very great nor lasting rains. For near a fortnight after, the sky looked always vapourish; and every day before dinner the sun endeavoured to create new suns, but in vain, either for want of matter, or of a due disposition. For in the vertical circle I saw plainly some sketches of parhelia for a long time. I saw also very manifest reciprocations of the lateral parhelia. The iris ORP seems to have been a portion of a single circle concentric to the sun, but towards $\varkappa$ and $\theta$ it did not quite touch the horizon AB; and the lengths of the arches O $\varkappa$, P $\theta$ were variable. The arches Z Q $\alpha$, $\beta$ Q $\gamma$, $\delta\varepsilon\zeta$, that immediately surrounded the sun, seemed to the eye to compose a single circumference, but it was confused, and had unequal breadths; nor did it constantly continue like itself, but was perpetually fluctuating. But in reality it consisted of the arches expressed in the scheme, as I accurately observed for that very purpose. The horns HRC seemed to be a portion of a smaller circle, touching the greater ORP in a contrary position in a common knot at R. The arches cut each other in a knot at Q, and there they formed a parhelion. The parhelia N, M, sprung out from the common intersections M, N of the iris $\delta\varepsilon\zeta$, and of the whitish circle ONMP. The north part of the sky was clearer than the south, which being overcast with slender vapours, afforded more matter for this appearance." See Gassendi's *Opera*, tom. vi. p. 401.

Hevelius observed the following paraselenæ at Dantzic on the 30th March 1660. "In the beginning, at one o'clock in the morning, the moon A was surrounded by an entire whitish circle BCDE, in which there were two mock moons at B and D, one at each side of the moon, consisting of various colours, and shooting out very long and whitish beams by fits. That on the left hand extended its tail towards the thigh of Serpentarius, the other on the right extended its tail towards Jupiter, as represented in Fig. 4. Afterwards, at two o'clock, a larger circle surrounded the lesser, and reached down to the horizon. The tops of both these circles were touched by coloured arches like inverted rainbows. The inferior arch at C was a portion of a larger circle, and the superior a portion of a lesser. This extraordinary sight lasted near three hours; the outward great circle vanished first of all, then the larger inverted arch at C, and presently the lesser, and, last of all, the inner circle BCDE disappeared. The diameter of this inner circle, and also of the superior arch, was 45 degrees; that of the exterior circle, and inferior arch, was 90 degrees."

On the 6th April 1660 Hevelius observed the parhelia shewn in Fig. 5. " At half an hour past five in the evening, while the sun was descending towards the horizon, he was crowned with arches of circles of various colours like the rain-bow. In the corona, on opposite sides of the sun, there were two parhelia, variously coloured with pretty long and whitish tails pointing from the sun. Near the zenith, where the corona was a little faint and imperfect, there shone out another inverted arch, having a third parhelion in the middle of it, which appeared somewhat obscure. This phenomenon lasted half an hour till sun-set, the sun being very clear. The inverted arch, and the upper parhelion, disappeared first; and then the parhelion on the left hand; but the third parhelion set with the true sun. The diameter of the corona round about the sun was about 45 degrees, as I guessed by my eye."

On the 17th December 1660, Hevelius observed at Dantzic, the following paraselenæ, which are shewn in Fig. 6. " On the first day after the full moon," says he, " at thirty minutes past six in the morning, the moon being 12° high, I saw the moon in the west, with three mock moons about her in this manner. The air being very clear at first, I observed the moon surrounded with a double corona (near her body, as the figure seems to represent) tinged with very bright and beautiful colours. On each side of the moon there were two arches of a large circle, about 45 degrees in diameter, which were also coloured like the rainbow, and extended down to the horizon, in which were two mock moons with very long white tails. That on the left hand was near Procyon with a short tail; the other on the right hand had a longer tail. In the upper part, where these collateral arches concurred, there was another arch inverted and variously coloured, with a third mock moon in the middle of it, and somewhat duller than the other two. Moreover, what was very extraordinary, there passed a large white rectangular cross through the middle of the moon, whose lower part reached down to the horizon; but on each side it did not quite touch the corona, as appears by the figure. It was so very bright and strong, that it shone distinctly and clearly till sun-rise; but the mock moons disappeared a little before."

In Mathew Paris's History, the phenomenon seen in Fig. 7. is thus described: " A wonderful sight was seen in England, A. D. 1233, April 8, in the 17th year of the reign of Henry III. and lasted from sun-rise till noon. At the same time, on the 8th of April, about one o'clock, on the borders of *Herefordshire* and *Worcestershire*, besides the true sun, there appeared in the sky four mock suns of a red colour; also a certain large circle of the colour of crystal, about two feet broad, which encompassed all England as it were. There next went semicircles from the side of it, in whose intersections the four mock suns were situated; the true sun being in the east, and the air very clear. And because this monstrous prodigy cannot be described by words, I have represented it by a scheme that shews immediately how the heavens were circled. The appearance was painted in this manner by many people, for the wonderful novelty of it."

Figure 8. represents a parhelion observed at Leyden, A. D. 1653, Jan. 14, between one and two o'clock in the afternoon, in the academical observatory, by Samuel Char. Kechelius a Hollenstein. " The circle BDC was white, and almost 35′ broad; the altitude of its highest point D was 38° 23′. Its centre was in the sun, whose height was 15° 48′; that is, at 36′ past one, his azimuth being 23° 40′ towards the west, and the angle made by his vertical circle and the ecliptic 60° 54′. The mock suns B, C were oblong and unequal, at the distance of 22° 35′ on each side of the sun, and had the same altitudes as the sun. The western parhelion at C was the fainter of the two, and changed from yellow to white, and disappeared first; the eastern one at B was brighter, with a lucid arch shooting from the sun, and was coloured with purple, red, and yellow; the shape of its tail BF was conical, 27° long, the parhelion being the base of the cone; the part BE, 13° 10′ long, consisted of bright yellow, and red light; the other part EF being whitish, which vanished before the parhelion did. It appeared for half an hour, and lasted one quarter longer than C; and the corona disappeared a little after."

On the 13th May, 1652, Huygens observed a halo, which he thus describes:—" I observed a circle about the sun in its centre; its diameter was about 46°, and its breadth the same as that of a common rain-bow. It had also the same colours, though very weak, and scarce discernible but in a contrary order, the red being next the sun, and the blue being very dilute and whitish. All the space within the circle was possessed by a duller vapour than the rest of the air, of such a texture as to obscure the sky with a sort of a continued cloud; but so thin, that the blue sky colour appeared through it. The wind blew very gently from the north."

On the 8th of April, 1702, Dr Halley observed a halo with parhelia, and tangent arches, as shewn in Fig. 9. where S is the sun, Z the zenith, STPP a large white circle passing through the sun, and nearly parallel to the horizon. It was about 2° broad in the northern part about T, and continued of the same breadth in the east and west; but grew narrower towards the sun. Its edges were not very well defined, and the whole circle, seen on the pure azure sky, was considered by Dr Halley as a very extraordinary sight. The halo VXNY was 22° in diameter, the red rays being nearest to the sun. The arch PVP had its centre nearly at N; and at its intersections P, P with the large white circle, there were two bright parhelia tinged with colours. The distance PS was $31\frac{1}{2}$°. Another arch appeared at N, having its centre about V. The height of the sun during the observation was from 40° to 45°. The weather was cooler than ordinary, and the vapour which produced the phenomena was higher than the clouds; for they were seen to drive under the circles. See *Phil. Trans.* 1702, vol. xxiii. No. 278, p. 1127.

A very curious halo, with its accompanying phenomena, was seen by Mr Barker on the 22d of January 1771, a little before two o'clock, at Fort Gloucester, on the river of Lake Superior. The weather was extremely cold. " There was a very large circle, or halo, round the sun, within which the sky was thick and dusky, the rest of the hemisphere being clear, and a little more than half way from the horizon to the zenith was a beautifully enlightened circle, parallel to the horizon, which went quite round, till the two ends of it terminated in the circle that surrounded the sun, where, at the points of intersection, they each formed a luminous appearance, about the size of the sun, and so like him when seen through a thick hazy sky, that they might very easily have been taken for him. Directly opposite to the sun was a luminous cross, in the shape of a St Andrew's cross, cutting at the point of intersection the horizontal circle, where was formed another mock sun like the other two. The two lower limbs of the cross appeared but faintly a little way below the circle. The two higher reached a good way above the circle towards the zenith, very clear and bright. In this horizontal circle, directly half way between the sun and the cross, and those at the ends of the same circle, were other two mock suns of the same kind and size, one on each side; so that in this horizontal circle were five mock suns, at equal distances from each other, and in the same line the real sun, all at equal heights from the horizon. Besides these meteors, there was, very near the zenith, but a little more towards the circle of the real sun, a rainbow of very bright and beautiful colours, not an entire semicircle, with the middle of the convex side turned towards the sun, which lowered as the sun descended. This phenomena continued in all its beauty and lustre till about half after two. The cross went gradually off first, then the horizontal circle began to disappear in parts, while in others it was visible; then the three mock suns farthest from the sun, the two in the sun's circle continuing longest; the rainbow began to decrease after these, and last of all the sun's circle; but it was observable at three o'clock or after it. See *Phil. Trans.* 1787, vol. lxxvii. p. 44.

On the 18th June 1790, a complicated system of halos and parhelia was observed at St Petersburg by M. Lowitz. They are represented in Fig. 10. The arches A, B, and C were coloured, and, like all the other coloured parts, had the red towards the sun. Two anthelia appeared at D and E.

A curious halo, observed by Mr Hall in Berwickshire, on the 18th of February 1796, about 10 o'clock, is shewn in Fig. 11. The moon was about south-west, and the altitude of her limb nearly 54°. The diameter of the great halo was about 112°; and that of the small halo, having the moon in its centre, was between 8° and 12°. The weather was remarkably mild, and there was little or no wind.

On the 20th of November 1802, at 2 o'clock, Sir Henry Englefield observed at Richmond in Surry, two uncommon halos and parhelia. The altitude of the sun was 14°. The circle nearest the sun (Fig. 12.) was about 24° distant from him, and about a degree broad. Its light was a pale yellow, without any of the prismatic colours. The exterior circle was 48° from the sun, and about 1½° broad. It was tinged with the prismatic colours, the red being nearest the sun. In the left branch of the inner circle, in a line parallel to the horizon, and passing through the sun, was a very faint parhelion; but in the upper point of the same circle was a very remarkable one. Its light was so vivid that it could scarcely be viewed, and it was rather brighter than the real sun. "It was of a whiter light than the rest of the circle in which it was, and had a pearly appearance, as partaking a little of prismatic tints. It was large, perhaps in its brightest part near 2° broad, very ill defined every where, but most diffused in the part farthest from the sun. From each side of the bright light proceeded a bright ray, which had a double curvature very distinct, being first convex towards the sun, and then concave. The lower edge of these rays (or that nearest the sun) was tolerably well defined; the upper edge melted away into the sky with a sort of streakiness. They grew both narrower and fainter towards their termination, and they reached pretty near to the other circle. The whole form of this parhelion and its rays bore so striking a similitude to the body and extended wings of a long winged bird, such as an eagle, hovering directly over the sun, that superstition would really have had little to add to the image. See the *Journals of the Royal Institution*, vol. ii. or Nicholson's *Journal*, vol. vi. p. 54. "A coloured drawing of this phenomenon, will be found in Dr Thomas Young's *Natural Philosophy*, vol. i. plate xxix. Fig. 431.

Having thus given a description of some of the most interesting halos and parhelia that have been accurately observed, we shall now proceed to give some account of the theories by which these phenomena have been explained.

Descartes supposes that halos are generated by the rays of the sun refracted through flat stars of pellucid ice; but it follows from this supposition, that the space within the halo should appear brighter than that without, which is contrary to observation. See Descartes, *Meteorolog.* cap. x.

The subject of halos was next investigated by Huygens, who published a large dissertation concerning their cause, which has been translated and reprinted by Dr Smith, in his *Treatise on Optics*. Huygens assumes the existence of particles of hail, some of which are globular, and others cylindrical, with an opaque portion in the middle of each, bearing a certain proportion to the whole; and he supposes these cylinders to be kept in a vertical position by a current of ascending air of vapours, and sometimes to have a position inclined to the horizon in all directions when they are dispersed by the wind or otherise. The cylinders are supposed to have been at first globules, formed of the softest and finest particles of snow. As soon as a globule is formed by a collection of these particles, many more particles will adhere to the bottom of it, but not to its sides, on account of the current of ascending vapours. The globules will thus have an oblong cylindrical figure; and when the warmth of the sun or of the air shall have melted the outsides of these cylinders, a smaller cylinder of snow will remain in the middle of each of them, surrounded with water; and after a certain part is melted, the cylinders within will become round and perfect, and will remain in this state for some time. If this coat of water should be frozen, Huygens supposes that it may possibly remain sufficiently transparent and polished to transmit, refract, and reflect the rays of the sun in a regular manner. By the aid of these assumptions, Huygens has ingeniously explained, in a very minute manner, almost all the principal phenomena of halos which had been seen at the time when he wrote. It is extremely improbable, however, that such hailstones do exist, and still more improbable that they should have such properties as to produce constantly the diameter of 47°.

Sir Isaac Newton ascribes the halo of 22½ degrees by refraction from floating hail or snow, and he accounts for the small coloured coronæ by his doctrine of fits of easy reflection and transmission. "As light reflected by a lens," says he, "quicksilvered on the backside, makes the rings of colours above described, so it ought to make the like rings of colours in passing through a drop of water. At the first reflection of the rays within the drop, some colours ought to be transmitted, as in the case of a lens, and others to be reflected back to the eye. For instance, if the diameter of a small drop or globule of water be about the 500th part of an inch, so that a red-making ray, in passing through the middle of this globule, has 250 fits of easy transmission within the globule, and that all the red-making rays which are at a certain distance from this middle ray round about it have 249 fits within the globule, and all the like rays at a certain further distance round about it have 248 fits, and all those at a certain farther distance 247 fits, and so on; these concentric circles of rays, after their transmission, falling on a white paper, will make concentric rings of red upon the paper, supposing the light which passes through one single globule, strong enough to be sensible; and in like manner the rays of other colours. Suppose now that, in a fair day, the sun shines through a thin cloud of such globules of water or hail, and that the globules are all of the same bigness, and the sun seen through this cloud shall appear encompassed with the like concentric rings of colours, and the diameter of the first ring of red shall be $7\frac{1}{4}°$, that of the second $10\frac{1}{4}°$, that of the third 12° 33′. And, according as the globules of water are bigger or less, the rings shall be less or bigger. This is the theory, and experience answers it. For, in June 1692, I saw, by reflection, in a vessel of stagnating water, three halos, crowns, or rings of colours, about the sun, like three little rainbows concentric to his body; the colours of the first or innermost crown were blue next the sun, red without, and white in the middle between the blue and red. Those at the second crown were purple and blue within, and pale red without, and green in the middle; and those of the third were pale blue within, and pale red without. These crowns inclosed one another immediately, so that their colours proceeded in this continual order from the sun outward; blue, white, red; purple, blue, green; pale yellow, and red; pale blue, pale red. The diameter of the second crown, measured from the middle of the yellow and red on one side of the sun, to the middle of the same colour on the other side, was $9\frac{1}{3}°$, or thereabouts. The diameters of the first and third I had not time to measure; but that of the first seemed to be about five or six degrees, and that of the third about 12°. The like crowns appear sometimes about the moon; for, in the beginning of the year 1664, February 19th, at night, I saw two such crowns about her. The diameter of the first or innermost was about 3°, and that of the second about $5\frac{1}{2}°$. Next about the moon was a circle of white, and next about that the inner crown, which was of a bluish green within next the white, and of a yellow and red without, and next about these colours were blue and green on the inside of the outward crown, and red on the outside of it. At the same time there appeared a halo, about 22° 35′ distant from the centre of the moon. It was elliptical, and its long diameter was perpendicular to the horizon verging below farthest from the moon. I am told, that the moon has sometimes three or more concentric crowns of colours encompassing one another next about her body. The more equal the globules of water or ice are to one another, the more crowns of colours will appear, and the colours will be the more lively. The halo at the distance of $22\frac{1}{2}°$ from the moon is of another sort. By its being oval, and remoter from the moon below than above, I conclude, that it was made by refraction in some sort of hail or snow floating in the air in an horizontal posture, the refracting angle being about 58° or 60°." See Newton's *Optics*, Book ii. Part iv. *Obs.* 13.

M. Mariotte supposes halos to be produced by small filaments of snow moderately transparent, and having the form of an equilateral triangular prism. He conjectures, that the hard flakes of snow which fall during a hard frost, and which have the figure of stars, are composed of little filaments like equilateral prisms, particularly those which are like fern leaves, as may be easily seen by the microscope. Upon examining the filaments which compose the hoar frost, he found them cut into three equal facets, and they exhibited rainbows when placed in the sun. Mariotte then supposes, that, before the hoar frost is formed, some of these separate prisms float among the thin vapours in the air, before they unite into the compound figures. "These little stars," says he, "are very thin and very light, and the little filaments which compose them are still more so, and may often be supported a long time in the air by the winds. Hence, when the air is moderately filled with them, so as not to be much darkened, many of them, whether separated or united, will turn in every direction as the air impels them, and will be disposed to transmit to the eye for some time a coloured light, nearly like to that which would be produced by equilateral prisms of glass." M. Mariotte then calculates the angles; and by deducting 16′ for the sun's semidiameter, and 30′ for the deviation of the red rays, he finds 22° 50′ to be the semidiameter of the halo produced by equiangular prisms.

In attempting to account for parhelia, Mariotte observes, "that they are usually at the same altitude as the sun. Among the prisms of snow, there are often many heavier at one end than at the other, and consequently situated in a vertical direction. These cause a bright parhelion with a tail, which cannot be above 70° long. I have read an account of a halo seen in May, soon after sun-rise, with parhelia in its circumference, which, after two or three hours, were more than a degree distant from it. This appearance arises from the coincidence of the sun's rays with the transverse section of the prism, when they are nearly horizontal, and from their obliquity, when the sun is elevated, causing a greater deviation, and throwing the parhelia outwards, as may be shewn by an experiment on two prisms." See Mariotte *Traité des Couleurs*, Paris 1686, or *Oeuvres de Mariotte*, vol. i. p. 272.

A theory of halos has recently been given by Mr Wood in the Manchester Transactions. He assumes, with Dr Halley, that vapour consists of hollow sphericles of water, filled with an elastic fluid, and having a thickness equal to $\frac{1}{122}$ of their diameter; and he supposes the halos to be produced by refraction, and reflection from these, in the same manner as the rainbow is produced by solid drops. See *Manchester Memoirs*, vol. iii. p. 336. A similar opinion seems to be entertained by M. Brande. See Gilbert's *Journal*, vol. xi. p. 414.

The subject of halos has recently been examined with much attention by our learned countryman Dr Thomas Young, who, before he was acquainted with the explanation of Mariotte, had adopted the very same theory. Our readers will no doubt be gratified with an account of Dr Young's theory and calculations in his own words.

"It is well known, that the crystals of ice and snow tend always to form angles of 60°; now a prism of water or ice of 60° produces a deviation of about $23\frac{1}{2}°$, for rays forming equal angles with its surfaces, and the angle of deviation varies at first very slowly as the inclination changes, the variation amounting to less than 3°, while the inclination changes 30°.

Now if such prisms were placed at all possible angles of inclination, differing equally from each other, one half of them would be so situated, as to be incapable of transmitting any light regularly by two successive refractions directed the same way; and of the remaining two-fourths, the one would refract all the light within these 3°, and the other would disperse the light in a space of between 20° and 30° beyond them.

In the same manner, we may imagine an immense number of prismatic particles of snow to be disposed in all possible directions, and a considerable proportion of them to be so situated, that the plane of their transverse section may pass within certain limits of the sun and the spectator. Then half of these only will appear illuminated, and the greater part of the light will be transmitted by such as are situated at an angular distance of $23\frac{1}{2}°$, or within 3° of it, the limit being strongly marked internally, but the light being externally more gradually lost. And this is precisely the appearance of the most common halo. When there is a sufficient quantity of the prismatic particles, a considerable part of the light must fall, after one refraction, on a second particle; so that the effect will be doubled; and in this case the angle of refraction will become sufficient to present a faint appearance of colour, the red being internal, as the least refrangible light, and the external part having a tinge of blue.

These concentric halos of 23½° and 47°, are therefore sufficiently explicable, by particles of snow, situated promiscuously in all possible directions. If the prisms be so short as to form triangular plates, these plates, in falling through the air, will tend to assume a vertical direction, and a much greater number of them will be in this situation than in any other. The reflection from their flat surfaces will consequently produce a horizontal circle of equal height with the sun; and their refraction will exhibit a bright parhelion immediately over the sun, with an appearance of wings or horns, diverging upwards from the parhelion.

For all such particles as are directed nearly towards the spectator will conspire in transmitting the light much more copiously than it can arrive from any other part of the circle; but such as are turned more obliquely will produce a greater deviation in the light, and at the same time a deflection from the original vertical plane. This may be easily understood, by looking at a long line through a prism held parallel to it: the line appears, instead of a right line, to become a curve, the deviation being greater in those rays that pass obliquely with respect to the axis of the prism; which are also deflected from the plane in which they were passing.

The line viewed through the prism has no point of contrary flexure, but if its ordinates were referred to a centre, it would usually assume a form similar to that which has often been observed in halos.

The form of the flakes of snow, as they usually fall, is indeed more complicated than we have been supposing; but their elements in the upper regions of the air are probably more simple. It happens however not uncommonly, that the forms of the luminous arches are so complicated as almost to defy all calculation. The coincidence in the magnitude of the observed and computed angles is so striking, as to be nearly decisive with respect to the cause of halos, and it is not difficult to imagine that many circumstances may exist, which may cause the axes of the greater number of the prisms to assume a position nearly horizontal, which is all that is required for the explanation of the parhelia with their curved appendages. Perhaps, also, the effect may sometimes be facilitated by the partial melting of the snow into conoidal drops; for it may be shown, by the light of a candle transmitted through a wine glass full of water, that such a form is accommodated to the production of an inverted arch of light, like that which is frequently observed to accompany a parhelion.

The situation of the lateral parhelia without the halo is very satisfactorily explained by Mariotte; and the diversified forms of the tangent arches may, probably, all be deduced from the suppositions laid down in the Journals of the Royal Institution. As an instance, we may take the case there described by Sir Henry Englefield, (see p. 615, *supra*,) where the sun's altitude was about 15°. The horizontal prisms will then cause an appearance of an arch with a contrary curvature, exactly as Sir Henry has described it.

The calculation is somewhat intricate. Its principal steps are these, taking the refractive power $\frac{4}{3}$.

Deviation of transverse rays 23° 37′.

For rays inclined 20°, the inclination of the planes of the rays is 29° 32′, the deviation 26° 12′; the altitude being 15°, the angle with the horizon is 25° 8′ more than the altitude.

For rays inclined 25°, the inclination of the planes is 34°, the deviation 27° 47′, the angle with the horizon 25° 47′ more than the altitude 15°.

For rays inclined 30°, the inclination of the planes is 120°; that is, the rays are in the planes of the surfaces, the deviation 38° 56′, the angle with the horizon 6° 4′ less than the altitude 15°.

When the altitude increases, the tangent arch descends so as to approach considerably to the halo, as in the halos observed by Halley and by Barker. For, calculating upon the true refractive power of ice, the angles become these.

For rays inclined 25°, the inclination of the planes 30° 55′, the deviation 25° 40′=21° 50′ + 3° 50′, the angle with the horizon 56° 24′=45° + 11° 24′. For altitude 15°, 38° 57′=15°+23° 57′.

It may also become double, the inferior arch being visible. Thus the angle with the horizon becomes 21° 18′ or 45°—23° 42′, as well as 56° 24′.

The mode of calculation is this: A being the inclination within the prism, and $r$ the index. Sec. B $= \frac{\text{Sec. A}}{\sqrt{\frac{3}{4}}}$ for the incidence; S. C$=r$. S. B, D $=$ C — B. As S. C : Sec. A :: S : D : $x$, $\sqrt{\frac{3}{4}}x = y$, $1 - y : \frac{1}{2}x$ :: Rad : T.E, 2 E is the mutual inclination of the planes passing through the rays and the axis of the prism, $\frac{\text{T.A}}{r} : \frac{1}{2}x$ :: Rad : S.F; 2 F is the whole deviation; $1 - \overline{y^2 + \frac{1}{4}xx} = zz$; $z : \frac{\text{T.A}}{r}$ :: S. Altitude : S. G, the elevation of the plane of the incident ray: G $\pm$ 2 E $=$ H, the elevation of the plane of the emergent ray; $\frac{\text{T.A}}{r}.z$ :: S.H : S I, the depression of the emergent ray.

Mr Cavendish has suggested, with great apparent probability, that the external halo may be produced by the refraction of the rectangular termination of the crystals, rather than by two successive refractions through the angles of different crystals, which, with the index 1.31, would produce a deviation of 45° 44′. If this supposition is true, the index cannot be greater than 1.31;* for 1.32 would give 47° 56′, which is more than appears to have ever been assigned.

The mean of four accurate observations is about 45° 50′, that of four of the best estimations 46°.

The lateral anthelia may be produced by the rays refracted after two internal reflections, which will have a constant deviation 60° greater than those which form the halo. These anthelia ought therefore to be about 82° from the sun. They are, however, usually represented as much more distant."

HALSTEAD, a town of England in the county of Essex, is agreeably situated on the acclivity of a gravelly eminence, at the foot of which passes the river Colne. The streets of the town are broad and airy, but many of the houses are old and inelegant. The church dedicated to St Andrew is an old building. It consists of a nave, chancel, and side aisles, and has a tower and spire at the west end. The spire is of wood, and is the third that has been erected, the other two having been destroyed by lightning. The grammar school was founded in the year 1594, by Dame Mary Ramsay, for 40 poor children of Halstead and Colne-Engaine. The direction of it is vested in the governors, &c. of Christ's Hospital, London. The Bridewell is an ancient building. There is a Greek inscription on a house in the parish, which was brought from a village near Smyrna, where it had been erected in honour of Crato a musician, about 150 years before Christ. Halstead formerly carried on a considerable trade in baize and serges, but it has of late much declined. In 1802, 1654 were returned as employed in manufactures, whereas in 1811 only 1170 were returned. In 1811, there were in the town and parish of Halstead,

HAM, or HAMM, in Latin *Hammona*, a town of Westphalia, and capital of the county of the same name, is situated near the place where the Asse throws itself into the Lippe. Its principal public buildings are its parish church and Calvinistic academy with three professors, and it has excellent establishments for the support of the poor. Ham was formerly one of the Hanseatic towns. It has long been celebrated for its excellent hams, which are called *hammen* in Holland, and for its fishery. Great quantities of linen are bleached here; and it is famous for a kind of beer called *reut*, which is sold to a considerable extent in the neighbourhood. Distance from Munster 6 leagues S. E. and from Cologne 18 leagues N. E.

HAMAH, *Epiphania*, and the *Apamea* of Strabo, is a town of Syria, situated in a narrow valley on the banks of the Orontes. It lies between Aleppo and Tripoli, and is about 30 leagues east of Tripoli, and 40 north of Damascus. It was founded by Seleucus Nicanor, who supported no fewer than 500 elephants in its fertile territory; and is famous for having been the place where the Romans, under Aurelius, defeated Zenobia, Queen of Palmyra. Hamah was destroyed in 1157 by a dreadful earthquake, but was afterwards rebuilt. This town is now celebrated for its water works, in which the water is raised from the river by wheels 32 feet in diameter. The water, falling into the buckets, is elevated to the height of 30 feet, and discharged into a reservoir, from which it is conveyed to the public and private baths. The gardens around are very agreeable and fertile, and the surrounding country is well adapted for wheat and cotton. The Maronites built a chapel and a tomb here, from which arose a convent which is celebrated in that part of Syria. There is here a strong castle. Hamah is the seat of a Jacobite bishop, and a pacha has the government of all the canton. Population, 4000. See M. De La Roque's *Voyage de Syrie*.

HAMBURGH is a free imperial city of the duchy of Holstein in Lower Saxony, and one of the largest, richest, and most populous cities in Germany. It is situated on the right or northern bank of the river Elbe, at the distance of about seventy miles from its discharge into the German Ocean. East Long. 9° 56′, North Lat. 53° 46′. The number of inhabitants fluctuates from 110,000 to 120,000.

The city is divided by a canal into the old and new town. It is built partly on islands, and partly on the continent of the north side of the Elbe. Towards the east it is washed by the small river Bil, and towards the north by another small river called the Alster, which forms a very large basin just without the town, and another about 1000 feet square within the walls, after which it passes through different parts of the city, and then discharges itself into the Elbe. The several islands formed by the rivers Elbe and Alster, on which the town is built, have a communication with each other by eighty-four bridges. The whole city is surrounded by a lofty rampart and a broad ditch. The town, although large and flourishing, is by no means elegant. The principal streets have long and broad canals, which are filled by the tide; the others, especially in the old town, are mean, narrow, and ill paved. The houses are mostly built after the Dutch fashion, and very lofty, several of them being six or seven stories high. The warehouses of the merchants are generally in the upper part of the building, to prevent damage from the frequent inundations occasioned by high floods in the river, the back part of the houses being commonly so near the water, that their vessels come to unload at the very doors. The most beautiful parts of town are the *Jungfernstoig*, which is the fashionable promenade, especially on Sundays, and the streets and alleys along the Alster. The principal public buildings in this city are, the churches of St Peter, St Nicholas, St Catharine, St James, St Michael, St John, and the cathedral. These are mostly Gothic structures, having lofty spires, beautiful altars, and large organs. From the spire of the church of St Michael, there is an extensive and charming view of the town and its environs. The exchange, the orphan-house, the several hospitals, the room-house, the house of Eimbeck, and the obelisk in honour of Professor Busch, are also worthy of notice.

Hamburgh was founded in the beginning of the 9th century, by Charles, the eldest son of the Emperor Charlemagne, who was commanded by his father to erect two forts on the Elbe, with the view of repelling the incursions of the Venedi, a Sclavonic nation inhabiting the southern coasts of the Baltic. The fort on the north side of the river was called Hammenburg, (whence, by abbreviation, Hamburgh,) or the castle near the wood, according to the etymology of the name given by Christopher Silvius, an ancient poet of Hamburgh:

> Hamburgum silva cui notum nomen ab Hama,
> Inter Billa tuos, et olorifer Alstria ductus.

This city has undergone a variety of revolutions. It was made an archbishop's see by Lewis the Debonnaire in 833; but the see was afterwards transferred to Bremen. Upon the extinction of the Carlovingian line, it became subject to the dukes of Saxony, of whom it was afterwards held by the counts of Holstein. Adolphus III. in conderation of a sum of money, with which the Hamburghers furnished him upon his expedition to the Holy Land, favoured them with a great many privileges, which were subsequently confirmed by the Emperor Barbarossa. The citizens afterwards purchased their entire liberty from Albert of Orlamund, Count of Holstein, for the sum of fifteen hundred marks of silver; and it was confirmed to them by succeeding counts, as well as by Christian I. king of Denmark, after the county of Holstein had devolved to that crown. The Danish kings, however, have, on several occasions, revived their claims to the sovereignty of this city, which has frequently obliged the inhabitants to pay very large sums for the confirmation of their liberties. But Hamburgh was declared a free imperial city in the year 1618, and was summoned to the diet of the empire in 1641.

The government of this city is vested in the senate and the three colleges of burghers. The former exercises the executive power, and has the right of assembling and dissolving the body of the burghers; the latter grant taxes, and administer the revenue. The senate consists of thirty-six persons, viz. four burgomasters, four syndycs, twenty-four counsellors, and four secretaries or clerks, the chief of whom is called a prothonotary. The burgomasters and counsellors only have votes. When a vacancy occurs, a new member is chosen by lot. The members of the legislative body are chosen from the five parishes or wards of the city. The first college consists of the aldermen, three of whom are chosen by the inhabitants of each parish. Every parish also sends nine persons to the second, and twenty-four to the third college. The ordinary business is regularly brought by the senate before this assembly; but when there is a new law to be made, or a new tax to be raised, after having passed this court, the measure must farther be laid before a general assembly of the burghers, in which every inhabitant householder may appear and give his vote.

Hamburgh is most advantageously situated for trade and commerce, both foreign and domestic. The Elbe forms a good harbour, being navigable for ships of large burthen until within four miles of the town, when they must unload into smaller vessels, which, by means of the canals which traverse the city, can be brought to the very doors of the warehouses. At the period when the Hanseatic league was formed, Hamburgh became a principal member of that celebrated confederacy, which brought the trade of the world to the ports of the Baltic and the north of Germany. In subsequent times, when the other nations of Europe, particularly the Dutch and the English, cultivated a more extensive commerce, the trade of Hamburgh, along with that of the other Hanseatic towns, declined. But its situation is so favourable, that it has always been able to command a considerable commerce, especially when the great maritime powers are at war, as Hamburgh then becomes the great mart for colonial produce destined for the supply of the continent of Europe. During the war of the French revolution, the trade of this city rapidly increased; and it still continued to enjoy the advantages of its situation, capital, and credit, under the continental system adopted by Bonaparte, in consequence of which, most of the ports of Europe were shut against the commerce with England. While the blockade of the Elbe continued, the merchants of Hamburgh still carried on a profitable, though circuitous, trade, by the Danish ports of Tonningen and Husum. But the prosperity of this commercial city received a severe blow by its forcible seizure and unnatural incorporation with the French empire, and the subsequent plunder of the bank. Since the overthrow of Bonaparte's system, and the consequent return of Hamburgh under its old laws and government, that city may be expected to recover, in some measure, its former prosperity and importance.

The commerce of Hamburgh consists 1*st*, In the export of its manufactured produce; 2*dly*, In the importation of foreign merchandise; and 3*dly*, In the re-exportation of these last articles to different parts of the continent. The principal manufactures of this city are, the refining of sugar, the printing of cotton cloths, the manufacture of velvets and silk stuffs, of laces, metal buttons, knit stockings, sail cloth, &c. The establishments for the refining of sugar, which are very numerous, have been long flourishing, and are esteemed among the best in Europe. It has been calculated that they produced daily 700 small loaves of sugar, of about 3½ pounds weight, and 400 large loaves, from 6 to 7 pounds. The raw sugar is procured chiefly from England, the earth used in purifying it from Rouen, and a great part of the manufactured article is exported to Russia. The printing of cotton formerly employed twelve establishments, which gave occupation to 600 workmen each; but their number has been since greatly reduced, in consequence of similar manufactories having been established in other countries. There are about twenty establishments for the manufacture of velvets and laces, which are exported to Russia and different parts of Germany. The manufacture of silk stuffs and woollens is inconsiderable, and only for home consumption. That of knit stockings is of more importance. They are sent into the interior of Germany, and some occasionally to Italy. Dyeing forms another branch of the manufactures of Hamburgh, whose dyers are esteemed the best in Germany. Besides its own manufactures, Hamburgh imports from England, France, Holland, Italy, &c. all sorts of rich silk stuffs, and the finest velvet brocades, besides fine cloths of all kinds, for the purpose of re-exportation. This city also exports timber to a considerable amount annually, particularly to France and Spain.

The number of vessels which entered the port of Hamburgh in 1791 was 1484; and the value of the imports, for the same year, amounted to 112,554,026 livres, or about 4,689,751*l.* sterling. After the raising of the blockade of the Elbe, the number of shipping which annually entered the port was calculated at from 1900 to 2000. The number of vessels belonging to the merchants of Hamburgh, and employed by them, amounted to about 400.

The bank of Hamburgh was established in the year 1619 upon the same principles with that of Amsterdam. It was intended as a general fund for the convenience of the merchants, who, by means of this institution, make and receive payment, without the intervention of specie, by a mere transfer in the books of the bank. The specie deposited consists of bank dollars and ingots of silver. This specie has no ordinary circulation; consequently the fund always remains entire; and the money of the bank thus serves as a standard for measuring the value of all other specie. The bank closes every year, from the last day of December to the 14th of January, for the purpose of balancing the books. It is under the direction of four of the principal persons of the city; and no person is entitled to have an account with it, who is not either a citizen or an inhabitant. There are two kinds of money at Hamburgh; real money, and money of account; the latter being partly real and partly imaginary. The mark *lub.* which is equal to about 1*s.* 6*d.* of our money, is divided into sixteen shillings, and each shilling into twelve fennings, or pence. The rix-dollar contains three marks *lub.* It is called the rix-dollar current, which must not be confounded with the rix-dollar of the bank, the latter being more valuable, and equal to about 4*s.* 10*d.* of our money. In general, the money of the bank is worth from 15 to 20 per cent. more than the current money, and the difference in exchange is called *agio*. Besides these, they have gold ducats, current at seven marks, more or less, and double ducats at fourteen marks. Foreign gold is also received at its intrinsic value, according to the rate of exchange, which is regularly advertised twice a week. The bank receives payment in its own money only. In the year 1725, the magistrates of Hamburgh resolved to coin some new specie, which is called the new current money of Hamburgh, and consists of pieces of 1 and 2 marks, of eight shillings, or half a mark, four shillings, or a quarter mark, and several of smaller denomination, conformable to the standard of the old dollar. The *agio* for this specie, in exchange with the bank, was fixed at 16 per cent. A new bank was also established, at the same time, for the convenience of the town, which could not receive any money but that coined in the city, the *agio* being regulated by a combination between the two banks. By these means, business is conducted with more ease and regularity, and the merchants are not liable to loss from the difference of value in the several denominations. The usance, or course of exchange, is at fifteen days sight, for bills drawn on any part of Germany; a month's date, for those drawn on France or on London; and two months for those drawn on Venice, or on Spain or Portugal. There are twelve days of grace allowed, including the day of the bill's falling due, the Sundays, and holidays.

The chamber of marine insurance was instituted in 1705. Six of the most wealthy merchants provided a fund, which was divided into 500 actions, or shares, of 100*l.* each; and the business has been conducted with the greatest success. There are also establishments for the other species of insurance. In the Lombard, or town pledge house, money is advanced, at an interest of six per cent. on every kind of goods and merchandise, without the intervention of a broker. When the time during which the sum was lent has expired, the goods must be redeemed; otherwise they are sold for their value, and the excess is faithfully transmitted to the person to whom they belonged. By this institution the town is said to gain about 150,000 crowns annually.

The police of this city is admirable. There are few or no beggars in the streets, as the magistrates take care to employ the indigent, who are able and willing to work, in the manufacture of knit-stockings, and to send all vagabonds and sturdy beggars, who refuse to work, to the house of correction. The few who are incapable of labour are maintained by their respective parishes. The establishments for the poor, indeed, are no where more liberal or better administered than at Hamburgh. They have a very large hospital for orphans, which possesses a revenue amounting to between six and seven thousand pounds. There is also a large hospital for the reception of poor infirm labourers, and another for aged and disabled seamen; besides many smaller institutions for poor widowers and widows, &c.; with two houses of correction, the *Zucht-Haus*, and the *Spinn-Haus*, in which malefactors are kept close at work, with a spare diet.

Citizenship, at Hamburgh, is personal. The son of a citizen, therefore, is not a citizen of right, but must purchase his franchise. A Hamburgher, or a stranger, who does not chuse to purchase the citizenship, must pay a stipulated sum annually to the town, to entitle him to engage in trade as a merchant, besides all the other duties and imposts to which the other citizens are liable. The income of the state is very large. It is composed partly of standing sources of revenue, and partly of occasional taxes granted by the community. The aggregate revenue is estimated at 3,800,000 marks, or about 285,000*l.* sterling. The established religion of the city is the Lutheran, and no other public exercise of religion is tolerated. But persons of a different persuasion may have an opportunity of attending worship at the chapels of the foreign envoys who reside in the city. The number of the clergy, including those of the dependent territories, amounts to fifty-three. The chief dependencies of this city are, the river Alster, the bailiage of Ham, some islands and low lands on the Elbe; and besides some districts acquired from Holstein, the bailiage of Ritzebuttel, to the north of the duchy of Bremen, including the port of Cuxhaven, and the isle called Neuwerk, situated opposite to that port.

The *Raths-Keller*, or town cellar, may be reckoned one of the curiosities of Hamburgh. It is an immense subterraneous cavern, which is filled principally with Rhenish wine. Several halls and chambers have been formed, for the entertainments frequently given there by the inhabitants and strangers. It is under the direction of a burgomaster, three senators, and three burghers; but the immediate management is committed to a steward, who makes a profitable business of it. There is also an apothecaries' hall belonging to the town, which contains a great quantity of every possible species of drugs. These being superior to those sold by the other apothecaries, have a considerable sale, and produce much profit to the city.

In Hamburgh there are numerous schools, libraries, and literary institutions, which reflect honour on the enlightened taste of its inhabitants; besides several valuable collections of paintings and prints, and cabinets of natural history, &c. which sufficiently prove that the arts and sciences have not been neglected amidst the pursuits of commerce. This city has been, at different periods, the residence of many literary characters of the first eminence, among whom the names of Lessing and Klopstock are conspicuous. The principal amusements of the inhabitants are music and dancing, card-playing and billiards; in winter riding upon sledges; and, in summer, walking or riding to public gardens in the environs of the town. There is a French and a German theatre; and the musical drama, or opera, has long been cultivated with activity and success at Hamburgh. The compositions of Keiser, Matheson, Handel, and Telemann, who all commenced their carrier in this city, are the most celebrated. C. P. E. Bach, the greatest musician of his time, succeeded Telemann as music director in 1767, and retained the situation until his death in 1788.

The merchants of Hamburgh are very luxurious in their style of living; the tone of society is easy and animated; and there is no place where strangers are entertained with more hospitality. See Nugent's *Travels through Germany;* Riesbeck's *Travels;* Peuchet *Dict. de la Geog. Com.* vol. iv.; Reichard, *Guide des Voyageurs; Account of the management of the Poor in Hamburgh; Hamburgische Künstler-Nachrichten.* Hamburgh, 1794. (*z*)

HAMEL, DU, du Monceau, Henry Lewis, an eminent vegetable physiologist, was born at Paris in the year 1700. In the Memoirs of the Academy for 1728, he published an Essay on a Parasitical Fungus, (*Sclerotium Crocorum* of Persoon), which infests the roots of the cultivated saffron; and, in the same year, appeared his Treatise on the Propagation of Trees by Grafting. His principal works on Botany and Vegetable Physiology were the following:

1. *Traité de la Culture des Terres.* Published in 6 vols. from 1750 to 1761.

2. *Elemens d'Agriculture.* 2 vols. 12 mo. 1764. This work was translated into English, German, and Spanish.

3. *Traité des Arbres et Arbustes qui se cultivent en France en pleine terre.* 2 vols. 4to 1755.

4. *Physique des Arbres.* 2 vols. 4to. 1758. This is the principal work of Du Hamel.

5. *Des Semis et Plantations des Arbres et de leur Culture.* 4to. 1760.

6. *De L'Exploitation des Bois, ou moyen de tirer parti des taillis demi futayes et haut futayes.* 2 vols. 4to. 1769.

7. *Du Transport, de la conservation, et de la force du Bois.* 4to 1767. See our article Carpentry. See also the *Mem. Acad. Par.* 1742, 1744, 1764, 1767, 1768.

8. *Traité des Arbres Fruitiers.* 2 vols. 4to. 1768.

Du Hamel was also the author of a treatise on the cultivation and preparation of madder. His works on the mechanical arts are numerous. The following, which were published separately, are the most important:

1. *Art de faire les cartes à jouer.*

2. *Art du Couvreur.* See *Mem. Acad. Par.* 1766. Hist. 156.

3. *Traite de la Corderie perfectionnée.*

4. *Art du Drapier.* See *Mem. Acad.* 1765. Hist. 132.

5. *Art de faire des Tapis.* See *Mem. Acad.* 1766, Hist. 157.

6. *Art de friser et de ratiner les etoffes de Laine.* See *Mem. Acad.* 1766, Hist. 156.

7. *Art de l'Epinglier.* See *Mem. Acad.* 1761, Hist. 152.

8. *Art de forger les enclumes.* See *Mem. Acad.* 1762, Hist. 188.

9. *Art de Peche.*

10. *Architecture Navale.* 4to. Par. 1758. See *Mem. Acad.* 1752, Hist 141.

11. *Art de la Fabrique des Ancres.* See *Mem. Acad.* 1761, Hist 152.

12. *Art de Fabriquer les Pipes.*

13. *Art du Potier de terre.*

14. *Art du Serrurier.*

15. *Art de reduire le fer en fil d'orchal.* See *Mem. Adac.* 1768, Hist. 128, 1778, Hist. 110.

M. Du Hamel died at Paris in 1782. See Botany, p. 30.

HAMELN, formerly called *Quern* or *Muchlen-Hameln*, is a town of Germany, in the kingdom of Hanover. It is situated in a pleasant territory, at the confluence of the Hamel and the Weser. It is very strongly fortified, and contains some good buildings, particularly the Hotel de Ville. Its barracks can accommodate a whole battalion. A fine sluice was erected here in 1734, by George II. for the purpose of facilitating the navigation of the Weser, by which the town carries on a considerable trade. Hameln has been celebrated for its tanneries, its breweries of beer, and for the manufactures which were established by the French refugees. There is here a refinery of sugar. At the mouth of a cave not far from the town is a monument, erected to commemorate the loss of 130 children, who were swallowed up in 1284. From the fort there is a very fine view of the surrounding country. Population 4000. Distance 30 miles south-west from Hanover.

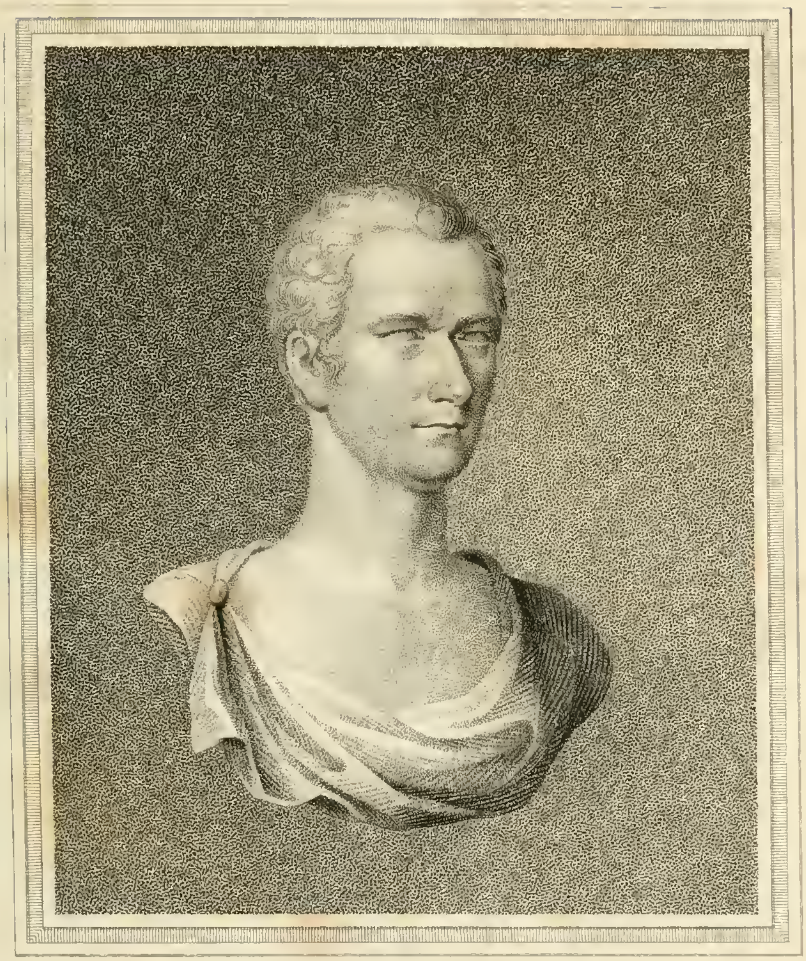
HAMILCAR. See Carthage.

---

HAMILTON, Alexander, first secretary of the treasury of the United States, a native of the island of St Croix, was born in the year 1757. His father was an English gentleman; and his mother an American lady. At the age of sixteen, he was placed at Columbia College, in the city of New-York; where he continued about three years. He was discovered, while engaged in his collegiate studies, to be a youth of most promising abilities. The contest between Great Britain and her then colonies of America engaged the attention, and employed the talents of many distinguished gentlemen on both sides. The pen of Mr Hamilton was early exercised in the support of the colonies. He asserted their claims against very respectable writers. His anonymous papers exhibited such evidences of wisdom, that they were ascribed to Mr John Jay, then in the possession of extensive fame as a statesman. When the real author was discovered, the Americans beheld with astonishment a youth of nineteen in the society of their ablest advocates. The first sound of war awakened his martial spirit. He entered the revolutionary army as captain of artillery; and soon conciliated the good opinion of his brethren in arms. He early attracted the notice of the commander in chief, Washington, who, in 1777, appointed him his aid, with the brevet-rank of lieutenant-colonel. His sound understanding, comprehensive views, application, and promptitude in duty, soon gained him the entire confidence of the general. In such company, it was natural that his genius should expand. By an alliance with Washington, by a close and discriminate survey of his military plans, by observing his consummate prudence, and by an attentive inspection of the resources he employed, in the preservation and maintenance of the army, in the most critical and embarrassing circumstances, he himself became eminently qualified for command. Throughout the war, he was active and ardent in the cause of independence; often rendered the most valuable services in the field; and was ever an able counsellor and expert amanuensis in the general's cabinet. In the campaign of 1781, which terminated with the capture of Lord Cornwallis, colonel Hamilton commanded a battalion of light infantry. At the siege of York, when the second parallel was opened, two redoubts of the enemy, in advance of his works several hundred yards, flanked it, and very much annoyed the Americans in the trenches. The commander in chief determined to have them carried by storm. The assault upon one was committed to American, and on the other to French troops. In the detachment of Americans, colonel Hamilton, at his own earnest request, led the advance, consisting of two battalions. Late in the afternoon, on the 14th of October, 1781, the several detachments rushed to the charge, without firing a single musket. The redoubts were assailed with irresistible impetuosity, and carried, unexpectedly, with little sacrifice of life. The enemy, in his feeble attempt to repel the storm, lost eight men. Notwithstanding the irritation lately occasioned in the American army, by an unwarrantable and savage slaughter of a surrendering garrison in Fort Griswold, not one man was killed who had ceased to make resistance. The forbearance of the irritated and victorious assailants, who commenced the charge with a determination to be revenged upon the murderers of their countrymen, was ascribed, in both armies, to the merciful interposition of colonel Hamilton.

With the conclusion of the war, which resulted in the independence of the United States, like his great friend, colonel Hamilton laid off the sword; and, having married destitute of fortune, began the study of the law, with a view to the support of his family. He was admitted to the bar, after a short course of preparatory reading; and soon rose to eminence in the profession. But his private pursuits could not wholly detach him from a regard to the public welfare.

In 1782 he was elected a representative in congress, from New-York, and occupied a very high rank in that body. Some of the most important business, ever transacted in the congress of the confederation, came under consideration while he was a member. It has been generally reputed, and the journals of the house abundantly prove, that he was the author of some, and an auxiliary in many, of the very



*Leney del.t et sc.t from the Bust by Ceracchi*

ALEX.R HAMILTON.

important measures then adopted. He was perhaps uniformly a member, and several times chairman, of the committees, to whom was confided the laborious duties of prior investigation, and reporting on such subjects as were deemed most vitally interesting to the nation. Those reports, notoriously prepared by himself, are full of eloquence, energy, and wisdom.

The violence, meditated against the property and persons of those who remained in the city of New-York during the late war, called forth his generous exertions in their behalf. By his influence, and the aid of governor George Clinton, the faithless and resentful schemes against them were defeated. On this occasion he published two celebrated pamphlets, under the signature of Phocion, addressed to the considerate citizens of New-York. Those excellent productions had the happy effect of calming the vindictive passions of the people, informing their minds as to the obligations arising out of the conclusion of the treaty of peace, and finally convincing them, that moderation and justice were not only most honourable, but most consistent with sound policy.

In the year 1786, colonel Hamilton was a member of the legislature of New-York. During the session, a collision, on the subject of territorial rights, which had subsisted between the people of that state, and the inhabitants of the territory, now state of Vermont, was quieted. It had become extremely violent, and menacing to the peace of that section of the United States. The happy result has been universally attributed to the wisdom of his measures, the influence of his character, the moderation of his temper, and the effect of his eloquence. Out of the pacification arose the independence of the state of Vermont, which was admitted into the union in 1791.

Before the expiration of the session of the legislature, in which his great talents had been so happily exerted, he was elected one of the representatives of the state of New-York, in the convention at Philadelphia, whose deliberations resulted in the formation of the federal constitution, which was afterwards adopted by the several states. No more weighty and highly responsible duties were ever conferred upon any assemblage of men, than those committed to the wisdom and prudence of the convention. They were none other than the preservation of the independence of the United States, after it had been asserted by the sword, and at the price of much valuable blood; and an equal distribution, among the people, of the rights, burthens, and benefits, which spring from government. The articles of confederation, formed in the season of war, and under the pressure of common danger, were found inadequate to the efficient government of the same country and people, in the time of peace and commercial enterprize. A radical reform became necessary.

The several confederations, at various periods, among the American colonies, for the purposes of defence, had left an impression on the public mind, of the practicability of permanent union. From the want of power, in that which carried the country safely and successfully through the war, to do any thing having the authority of law, the affairs of the United States became exceedingly perplexed. Commercial jealousies were fast increasing among the several states, and countervailing measures were resorted to, not calculated to maintain the good understanding, which it was hoped would continue to exist among states that harmonized in the resistance of a common enemy. The sufferings of the inhabitants were increased by obstructions in their trade, from which they had been free while colonists. That intercourse with the West Indies, from which they had usually derived great supplies of gold and silver, was forbidden them, in their novel capacity of independent states. Their fisheries received a severe check, in their exclusion from several ports in which they had been accustomed to find ready sale of the fruits of their industry. These evils were still further aggravated by the stoppage of the bounty on whale oil, to which, when British subjects, they were entitled. To add to their misfortunes, they could no longer navigate the Mediterranean in safety; a privilege which they had enjoyed while members of the British empire. Unable to defend themselves against the barbarian corsairs, they were obliged either to quit the sea, or insure their trade at a ruinous premium. In short, the channels of commerce, which had been familiar to them, in their new character of citizens of the United States were completely changed. For the sums needed in the public service, the congress of the confederation continued to send forth annual requisitions; but, as they rested merely upon the recommendation of that body, it was optional with the state legislatures to grant them. They were consequently disregarded by some of the states, and but partially complied with by others. From this failure of public justice, a deluge of evils was likely to flow. It was moreover swelled by an unfavourable balance of trade. The ravages of armies, and the interruption of a free communication between America and Europe, during the war, had multiplied the wants of the former. An inundation of European manufactures was, therefore, one of the early incidents which followed the establishment of peace. They were purchased by the Americans far beyond their means of payment. Adventurers, grasping at the profits of trade with the new formed states, exported to America goods to a great amount; exceeding what either prudence or policy could justify. The Americans found themselves involved in debt, to the discharge of which their resources were unequal. In many instances these debts were contracted on credit, by persons to whom the United States were indebted. Presuming on the justice and ability of their country, they had involved themselves in private engagements, trusting, for the means of discharging their obligations, on payment from the public. To relieve their constituents from the pressure of multiplied and accumulating evils, congress felt its inadequacy; and called on the states to enlarge their powers, and particularly to entrust them with the regulation of commerce; at least for a limited number of years. Some states complied with the call; but others fettered their grants with such conditions as prevented the formation of an uniform system. From the combined operation of these causes and effects, trade languished; credit expired; gold and silver vanished; and real property depreciated to an alarming extent. Instead of creating an artificial medium of circulation by funding their debts, several of the states, to alleviate the distresses arising from the want of money, adopted the fallacious expedient of emitting paper, to supply the place of gold and silver; but the remedy increased the disease. Owing to the imbecility of the existing government, the public debt could not be funded upon any basis that would command confidence; and the advantage of substituting it for metal, as the basis of a national monied institution, was lost. The people began to feel disappointment in their expectations of prosperity and happiness as the fruits of independence. The calamities of war were followed by another class of evils, different in their origin, but not less oppressive in their consequences. The citizens were now peculiarly liable to be led into fatal error They were sensible of pressure, and, not knowing precisely from what sources it originated, or how to remedy it, became restless, and ready to adopt any desperate measures recommended by ambitious and turbulent leaders. In this irritable state, an insurrection actually commenced with a number of the citizens of Massachusetts, who, sore with their enlarged portion of public calamity, were induced, by seditious demagogues, to make open resistance to the operations of their own free government. The votaries of liberty and independence began to be less sanguine in their hopes from the revolution; and to fear that they had reared a visionary fabric of government on fallacious ideas of public virtue. At length, however, recurrence was had to the good sense of the people for the rectification of fundamental disorders. The congress adopted a resolution to the following effect: "That in their opinion it was expedient, that, o nthe second Monday of May, 1787, a convention of delegates, who shall have been appointed by the several states, be held at Philadelphia, for the sole and express purpose of revising the articles of confederation, and reporting to congress, and the several legislatures, such alterations and provisions therein, as shall, when agreed to in congress, and confirmed by the states, render the federal constitution adequate to the exigencies of government, and the preservation of the union." The states accordingly appointed delegates, who assembled in convention, at Philadelphia, at the time appointed. General Washington was nominated president, on the organization of that illustrious and patriotic body. After deliberating nearly four months with closed doors, the convention agreed upon a plan of government, which was reported to congress, "as the result of a spirit of amity, and of that mutual deference and concession, which the peculiarity of their political situation rendered indispensable;" and that, in their opinion, "it should be submitted to a convention of delegates chosen in each state, by the people thereof, under the recommendation of their legislature, for their assent and ratification." The plan of government, reported by the convention, was the present constitution of the United States; which was adopted by the people of the several states in conventions assembled. A glance at the political condition of the country, and an accurate estimation of the dispositions of its inhabitants, at the very solemn and interesting juncture when the convention met at Philadelphia, will sufficiently attest the fortitude of its members, in undertaking, at such a period, the formation of a government to be spontaneously adopted, and yet to be sufficiently energetic to enforce obedience to its authority. Great was their responsibility; and heavy was the load of anxiety which must have hung on their minds, lest their efforts should at last be lost in failure.

The particular services of colonel Hamilton, in the convention, are not accurately known to the public, as that body sat in conclave, and their journals have never been published. It has been remarked, however, by a very respectable member of the convention from a neighbouring state, "that, if the constitution should not succeed on trial, Mr Hamilton was less responsible for such a result than any other member; for he fully and frankly pointed out to the convention, what, he apprehended, were the infirmities to which it was liable: And that, if it answered the fond expectations of the public, the community would be more indebted to him than to any other member; for, after its essential outlines were agreed to, he laboured most indefatigably to heal those infirmities, and to guard against the evils to which they might expose it." It is believed that, in this declaration, his colleague did not do him more than justice.

After the publication of the constitution, colonel Hamilton, in concert with Mr Jay, of New-York, and Mr Madison, of Virginia, commenced the publication of the *Federalist;* a series of essays under the signature of ***Publius***, addressed to the people of New-York, in support of the constitution, and in favour of its adoption. These papers made their first appearance, in the public prints, early in November, 1787. The series was not concluded until a short time previous to the meeting of the state convention, in June 1788. It is well understood that Mr Jay took upon himself a slender share of the work; that Mr Madison composed not a few numbers; but that colonel Hamilton was not only principal author, and wrote at least three-fourths of the volumes, but superintended its publication. The Federalist is not to be classed among those ephemeral productions calculated only for party purposes, and, when those purposes are served, to sink into oblivion. It is a profound and learned disquisition on the principles of federal representative government; and combines an ardent attachment to public liberty, with an accurate discernment of the dangers resulting from an excessive jealousy of power. It will endure as long as the republican institutions of the United States; on which it is a luminous and eloquent commentary. The Federalist was translated and published in France, by Buisson, just as its inhabitants were setting out in the mad career of their revolution. By the sedate and learned politicians of that country, it was esteemed a most excellent work. The wild, furious, and unstable partizans, who conducted the people to the perpetration of the most shocking cruelties, deemed it aristocratical in its tendency. If the leaders of the French revolution had thoroughly studied the Federalist, and received light from this western star, they might possibly have rescued the people from the fury of their tempestuous passions; from a continued vibration between scenes of folly and scenes of horror; and conducted them in safety to peace, independence and liberty. In the United States the Federalist had great popularity; circulated through every part of the country; enlightened the understandings of the people on the nature of government; and warmly disposed them to a preference of the federal representative system. It was eminently successful in the end intended by its authors.

Colonel Hamilton was a member of the state convention of New-York, which assembled in the summer of 1788, to deliberate on the adoption of the Federal constitution. It had to encounter very serious opposition. For a time, the issue of the contest between its advocates and opponents was doubtful; but his argument and eloquence at length overcame hostility, carried conviction to the minds of its adversaries, and finally, and most happily for the union, procured its adoption by the populous and powerful state of New-York.

On the organization of the federal government, in 1789, the president, Washington, selected colonel Hamilton as the secretary of the treasury. The duties of that department, intrinsically difficult, and connected with high responsibilities, were confessedly, at the time, encumbered by much embarrassment and entanglement, produced by the operation of temporary but influential causes; and when recurrence is had to the measures that were originated, matured, and vindicated by him, the candid mind is overwhelmed with astonishment, in the contemplation of the various powers of his vigorous and exalted mind. His reports are so many didactic dissertations, laboriously wrought, and highly finished, on some of the most intricate and abstract subjects in political economy. Among his reports it is proper particularly to designate, as the most interesting, those of January, 1790, on a provision for the support of the public credit; of December, 1790, on the establishment of a national bank; of December, 1791, on the subject of manufactures; and of January, 1795, on a plan for the further support of public credit.

Colonel Hamilton was justly regarded by the intelligent and candid public men in his day, and is now almost universally reputed, the founder of the public credit of this country. He raised it from the dust, and placed it on sound foundations. If it have ever been shaken, the casualty did not arise from any defect in his system, but in the departure from it, by some of his more recent successors. So terribly was the country menaced, by the effects of the temporary abandonment of his financial axioms, in the course of the more recent war between the United States and Great Britain, that it may well be asserted they will never again be suspended. They have now become the fundamental principles of the treasury department. The main spring of public credit, according to the now established fiscal principles of the United States, is good faith ; and a punctual performance of contracts. That the national credit might be placed beyond the reach of doubt, suspicion, or distrust, those enemies to the equal and steady operation of all monied institutions, whether under the direction of individual associations or of government, he urged on congress the express renunciation, by law, of all right to tax the public stocks, or to sequester at any time, or on any pretence, the property of foreigners therein. He qualified the United States to know, develope, and realize their immense resources. Under his administration, the finances advanced to a point of prosperity beyond all expectations. Nor was the credit of the government confined to its own constituents. The stocks of the United States engaged the notice and commanded the attention of capitalists in every part of Europe. At the present moment, in England, six per cent. per annum is above par. It will be observed, in reading his reports on the means of supporting public credit, that he was unfriendly to the accumulation of public debt. He considered a heavy load of debt a disease of the most baneful character; and often fatal to free governments. He maintained that it ought to be guarded against with provident foresight, and inflexible perseverance. It was a fundamental maxim in his system of public credit, and which he uniformly exhibited in his practice, *that the creation of debt should always be accompanied with securities pledged for its extinguishment.* The observance of this wholesome and well-tried specific is the true recipe to render public credit immortal. In his last report in relation to the national debt, he recommended a provision to augment the sinking fund, so as to render it commensurate with the whole debt of the United States ; and proposed to secure that fund by a stipulation the most inviolable, no less than to make the application of the fund to the object a part of the contract with the creditor. By such means, and with such efforts, did he support the initiation of the new government, in its most tender and delicate department ; and build up and establish on solid principles the important interests of the nation confided to his care. He has left little else to be done by his successors, than to follow his precepts ; and earn to themselves fame, by imitating his administration.

His report on manufactures is perhaps the most elaborate performance he left on the files of his office. It is distinguished for extensive research, judicious application of the knowledge attained, and an accurate estimate of the policy of encouraging the manufacturing interest. It is an essential feature in the independence of the nation. This report adopts the principles of the mercantile system, in opposition to the celebrated Adam Smith and the French economists. They attacked the combined manufacturing and mercantile interests of Great Britain, as founded upon oppressive monopoly ; and contended for entire freedom of commerce and industry, undiverted and unimpeded by government, as the best means of advancing nations to prosperity and greatness. The secretary combated with the greatest ability some of the dogmas of these philosophers; and maintained his favourite system as much by the power of his logic, as by illustrative and pertinent reference to the experience of those nations, at once successful in commerce and great in the productions of art. It is now twenty-six years since his report on manufactures was made to congress. Just now his opinions on that great branch of natural economy are becoming popular in the United States. Societies are now forming in every part of the country, composed of gentlemen in all the various pursuits of life, expressly to procure and disseminate information tending to encourage the manufacturing interests of the nation. Memorials, of most interesting and impressive character for eloquence, correct principles, and patriotic devotion, have been published to the people; and committees appointed, to stimulate the federal government to a particular patronage of that branch of industry and political strength. These memorials and committees espouse the sentiments which were assumed by secretary Hamilton. In this particular, as on the subjects of the funded debt and national bank, the experience of the last quarter of a century has clearly proved, that he was, in his time, more correctly impressed as to the true interests and policy of the United States, and better understood their political and domestic economy, than any other statesman who has been at all prominent in their public affairs. All his official reports are remarkable for wide research, profound thought, close logic, and precision of expression. His labours in the treasury department, united with the integrity with which he conducted it, and which the most penetrating inquisition into all the avenues of his office could never bring into question, will form with posterity the fairest monument of his fame.

In his capacity of secretary of the treasury, he was also one of the executive counsellors ; and it is believed few, if any, matters of moment were transacted without the sanction of his opinions. The period of his confidential and official connection with the government was unusually critical. The French revolution raged with great violence ; and threatened to involve the whole civilized world in its inflammatory course. A war of great inveteracy existed between Great Britain and France. At this crisis, M. Genet was sent minister to the United States, charged with secret instructions, afterwards published, to excite the American people to make common cause with France. To meet this important epoch, in consonance with the advice of secretary Hamilton, a proclamation of neutrality was issued by the president. To defend that prudent measure against the prejudices and passions which the French minister was enabled to excite, the essays under the signature of *Pacificus* were published. These essays were written by the secretary in the summer of 1793; and of all his publications, none appeared at a more seasonable juncture, or produced a more salutary effect. Their end was to prove, that the president had competent authority to issue the proclamation of neutrality ; that it only went to declare the existing lawful relations of the American government ; and that, as the constitutional executor of the laws, it was his bounden duty to see them faithfully observed ; that the United States were under no obligations from existing treaties to become a party in the war between England and France ; that, considering the peculiar origin and nature of their contention, the United States had sufficient reasons against any interference ; that the obligations of gratitude imposed upon nations the mutual returns of good will and benevolence, but were no sufficient grounds for taking part in their wars; and that those obligations more naturally pointed to the hand from which antecedent favours had been received, and which, in the present case, was the amiable and unfortunate monarch, whom the revolution in France had recently swept from his throne. The proclamation afterwards received the sanction of congress, and of the community at large.

In January 1795, secretary Hamilton resigned the direction of the treasury department, and once more returned to private life. He still felt himself charged to vindicate another important measure of the government, of which he had been a strenuous advocate; but which had been distorted not a little by party-misrepresentation—Jay's treaty with Great Britain. This treaty had to encounter inveterate prejudices, which had their root in the animosities of the revolutionary war, and which had been rekindled, and armed with increased violence, by the effects of the French revolution on the minds of the American people. Even at this day, it is delicate to comment on some of the events produced by the spirit of party at that period. The ex-secretary devoted all his leisure from professional avocations, in the summer of 1795, to a defence of the treaty, in a series of essays, under the signature of *Camillus*. Error and prejudice were dissipated by their point and truth. The treaty was ratified; and the nation consequently derived great and immediate advantages from the provisions relating to the western posts, and the liquidation of unsettled claims; and subsequently enjoyed a long course of commercial prosperity.

The last great occasion which called secretary Hamilton upon the theatre of public action, arose in 1798. France for some years had been making depredations upon the commerce of the United States. A pacific adjustment by negociation had been repeatedly attempted on their part without success. Their minister had been refused audience. Three ministers extraordinary had been treated with unwarrantable contumely; and money was demanded of them on the most degrading terms, and in the most indignant manner. The door of reconciliation being thus closed, they had left no honourable alternative but open and determined resistance of injury and insult. France was a power the most terrible in strength; the most daring in project; the least scrupulous in the choice of means; the most fatal to its victims, of any that a righteous Providence had hitherto permitted to rise up for the chastisement of the human race. All the republican states of Europe within her wide-spreading grasp, the United Netherlands, Geneva, the Swiss Cantons, Genoa, and Venice, had already been prostrated by her arms, or her still more formidable caresses. She was at the moment rioting in schemes of universal domination; and was actually fitting out a vast armament, in the ports of the Mediterranean, for some expedition of conquest or plunder. At this portentous period, the ex-secretary published *The Stand*, a series of essays, under the signature of *Titus Manlius*, with the view to arouse his fellow-citizens to a sense of impending danger, and to prevail on the government without delay to adopt measures of defence, at once vigorous and manly.

The *Stand* glowingly pourtrays the conduct of revolutionary France towards her own people, and towards other nations; and shows that she had undermined the main pillars of civilized society; that she betrayed a plan to disorganize the human understanding itself, by destroying all religious sentiment, and perverting a whole nation to atheism; that her ruling passions were ambition and libertinism; and that she aimed equally to proselyte, subjugate, and debase every government without distinction, to effect the elevation and aggrandizement of the "Great Nation." It details the accumulated injuries and insults the United States had received from France; and demonstrated, that her object was to degrade and humble their government, excite the American people to revolution, and prepare the way to conquest for herself. In the conclusion, it recommends a suspension of the good understanding which had subsisted between the United States and France; fortification of their harbours; to defend their commerce on the ocean; attack her predatory cruisers on our coast; create a respectable navy; raise, organize, and discipline a provisional army; as indispensible precautions against attempts of invasion, which might distress the inhabitants of the Atlantic border, and seriously prejudice the domestic peace of the nation. Finally, it entreats the people and government of the United States, having taken the attitude recommended, to meet the aggressor in the spirit and fortitude of calm defiance. So undeniable were the facts; so irresistible the conclusions; and so palpable the policy recommended, that, in 1798, the measures suggested by the writer were all literally carried into execution by congress, and approved by a majority of the nation. An honourable, proud, and manly sentiment pervaded the people. The *Stand* reflected honour on the national character. That character was respected in Europe; and afforded additional security to the rights of the United States.

A provisional army was voted by congress; and the late secretary, upon the express solicitation of Washington, the commander in chief, with the rank of lieutenant-general, was appointed inspector-general. The following extract of a letter from general Washington, insisting upon the appointment of Hamilton second in command, and inspector-general, exhibits the sentiments entertained of his merits, by one of the best judges of men: "It is, at all times, an invidious task to draw comparisons; and I shall avoid it as much as possible: but I have no hesitation in declaring, that, if the public is to be deprived of the services of colonel Hamilton, in the military line, the post he was destined to fill will not be easily supplied; and, that this is the sentiment of the public, I may venture to pronounce.

"Although colonel Hamilton has never acted in the character of a general officer, yet his appointment, as the principal and most confidential aid of the commander in chief, afforded him the means of viewing every thing on a larger scale than those who had only divisions and brigades to attend to. By some, colonel Hamilton is considered an ambitious man, and therefore a dangerous one. That he is ambitious I shall readily grant: but his ambition is of that laudable kind which prompts a man to excel in whatever he takes in hand. He is enterprizing; quick in his perceptions; and his judgment intuitively great; qualities essential to a great military character: and therefore I repeat his loss will be irreparable." A loftier eulogium on the merits of general Hamilton could not be written. Its excellence consists in the opportunities the writer had enjoyed of knowing him intimately; for every one acquainted with general Washington will readily admit, that his opinions and candour were always entitled to the highest consideration.

Invested with the rank of inspector-general, Hamilton repaired to his post; and immediately entered upon the duties of his office. The organization and discipline of the army were the appropriate duties of his department. The condition and police of the army, in a short time, supported the expectations of the commander in chief. The arts of war became his constant study; and the knowledge he acquired by research, he happily disseminated among the subordinate officers, who in turn diffused it through the ranks by assiduous drilling.

On the death of the commander in chief, in 1799, general Hamilton succeeded to the command of the army. Hostilities between the United States and France having terminated, and the provisional army having been disbanded, he here turned to the bar, and never afterwards filled any public station; but devoted himself exclusively to the duties of his profession. Notwithstanding the great majority of his days had been spent in the public service, his abilities, industry, integrity, and eloquence, advanced him to the highest estimation as a lawyer and advocate. He was decidedly foremost in New-York; and it is believed he had no superior in the United States. He had the intuitive strength of Marshall, the learning of Parsons, and the eloquence of Henry. In the full possession of great influence over the public mind, and enjoying the entire confidence of every one, he had the prospect of running a long, brilliant, and lucrative professional career: but a sad catastrophe arrested him in the midst of his years; spoiled the hopes of his family; and deprived his country of one, whom she had always accounted second only to Washington.

Aaron Burr, late vice president of the United States, by his endeavours in the year 1801 to supplant Mr Jefferson as the president, lost the confidence of his political friends. So early as he ascertained, that he could no longer look to them for the indulgence of his ambition, he began to cast about for a plan to recover his influence in the country. One was presented to his view, which he eagerly pursued, with no little promise of success. He became a candidate for the office of chief magistrate of New York, at the election in April, 1804; and calculated on success, from a combination of his yet powerful personal friends with the federal party of the state. It was supposed that the coalition would ensure an ascendancy. The scheme was generally favoured by the federalists; and would probably have succeeded, but for the decided opposition of general Hamilton; whose influence enabled him to defeat the coalition, and prostrate the hopes of colonel Burr in the dust. The election having terminated in his disappointment, colonel Burr determined to be revenged on the author of his political overthrow. For this purpose, he addressed a note to general Hamilton, demanding a prompt and unqualified acknowledgment or denial of the use of certain expressions imputed to him, and deemed derogatory to the honour of colonel Burr. The demand was adjudged inadmissible; and a duel was the consequence. The parties met at Hoboken on Wednesday morning, 11th of July, 1804; and, at the first fire, general Hamilton fell, on the same spot where his son a few years before had fallen, in obedience to the same principle of honour, and in the same violation of the laws of God and of man. He was carried into the city; and, being desirous of receiving the sacrament of the Lord's supper, he immediately sent for the reverend Dr Mason. As the principles of his church prohibited him from administering the ordinance in private, this minister of the gospel informed general Hamilton, that the sacrament was an exhibition and pledge of the mercies which the Son of God has purchased, and that the absence of the sign did not exclude from the mercies signified, which were accessible to him by faith in their gracious author. He replied, "I am aware of that. It is only as a sign that I wanted it." In the conversation which ensued, he disavowed all intention of taking the life of colonel Burr; and declared his abhorrence of the whole transaction. When the sin, of which he had been guilty, was intimated to him, he assented with strong emotion; and when the infinite merit of the Redeemer, as the propitiation for sin, the sole ground of our acceptance with God, was suggested, he said with emphasis, "I *have* a tender reliance on the mercy of the Almighty, through the merits of the Lord Jesus Christ." The reverend bishop Moore was afterwards sent for, who, after making suitable inquiries of the penitence and faith of general Hamilton, and receiving his assurance, that he would never again, if restored to health, be engaged in a similar transaction, but would employ all his influence in society to discountenance the barbarous custom, administered to him the communion. After this his mind was composed. He expired about two o'clock on Thursday, July 12, 1804, aged about forty-seven years.

The dying act of general Hamilton affords much consolation and comfort to the humble christian believer. How clearly did it show, that the religion of Jesus is that alone which can impart courage and cheering hope to a departing soul! Hamilton had the intellect of a Solon, and the philosophy of a Plato; but these were not his stay in the hour of death. Hamilton had influence and honour among men; but they could not relieve one dying pang. The critical moment at length arrived. On what did he cast the safety of his soul? Hear himself! "*I have a tender reliance on the mercy of the Almighty, through the merits of the Lord Jesus Christ.*" Yes, the great Hamilton, who filled the world with his fame, when dying, bore his testimony to the insufficiency of every other hope, save that which accompanies the christian over the threshold of life.

The last solemn moment came. Hamilton laid down his great human labours, and all his honours, as worthless and unavailing. To the exclusion of every other concern, *religion* claimed all his thoughts. Jesus! Jesus, is now his only hope. The *friends* of Jesus are his *friends*—not armed with the weapons of blood and death—but armed with the word of life and of truth. The ministers of God, with the words of pardon and reconciliation on their lips, are his companions. While these intercede, he listens in awful silence, or in profound submission whispers his assent.

Sensible, deeply sensible of his sins, he pleaded no merit of his own. He repaired to the mercy-seat, and there poured out his penitential sorrows: there he solicited pardon.

Heaven, it should seem, heard and pitied the suppliant's cries. Disburdened of his sorrows, and looking up to God, he exclaimed, "Grace—rich grace!" "*I have*," said he, clasping his dying hands, and with a faltering tongue, "*I have a tender reliance on the mercy of God in Christ.*" In token of this reliance, and as an expression of his faith, he received the holy sacrament; and having done so, his mind became tranquil and serene. Thus he remained, thoughtful indeed, but unruffled to the last, and met death with an air of dignified composure, and with an eye directed to the heavens.

This last act, more than any other, shed glory on his character. Every thing else death effaced. Religion alone abode with him on his death-bed. He died a christian. This is all which can be enrolled of him among the archives of eternity. This is all that can make his name great in heaven.

Let not the sneering infidel persuade us, that this last act of homage to the Saviour resulted from an enfeebled state of mental faculties, or from perturbation occasioned by the near approach of death. No; his opinions concerning the divine mission of *Jesus Christ*, and the validity of the holy scriptures, had long been settled, and settled after laborious investigation and extensive and deep research. These opinions were not concealed; and had his life been spared, it was his determination to have published them to the world, together with the facts and reasons on which they were founded.

When scepticism, shallow and superficial indeed, but depraved and malignant, breathes forth its pestilential vapour, and pollutes, by its unhallowed touch, every thing divine and sacred; it is consoling to a devout mind to reflect, that the great, and the wise, and the good of all ages; those superior geniuses, whose splendid talents have elevated them almost above mortality, and placed them next in order to angelic natures—yes, it is consoling to a devout mind to reflect, that, while *dwarfish infidelity* lifts up its deformed head, and mocks, these *illustrious personages*, though living in different ages—inhabiting different countries—nurtured in different schools—destined to different pursuits—and differing on various subjects—should all, as if touched with an impulse from heaven, agree to vindicate the sacredness of Revelation, and present, with one accord, their learning, their talents, and their virtue, on the gospel altar, as an offering to Emanuel.

This is not exaggeration. Who was it, that, overleaping the narrow bounds which had hitherto been set to the human mind, ranged abroad through the immensity of space, discovered and illustrated those laws by which the *Deity* unites, binds, and governs all things? Who was it, soaring into the sublime of astronomic science, numbered the stars of heaven, measured their spheres, and called them by their names? It was Newton: but Newton was a christian. Newton, great as he was, received instruction from the lips, and laid his honours at the feet of *Jesus*.

Who was it, that developed the hidden combination, the component parts of bodies? Who was it that dissected the animal, examined the flower, penetrated the earth, and ranged the extent of organic nature? It was Boyle: but Boyle was a christian.

Who was it, that lifted the veil which had for ages covered the intellectual world, analyzed the human mind, defined its powers, and reduced its operations to certain and fixed laws? It was Locke: but Locke too was a christian.

To these may be added, *Hale*, learned in the law; *Addison*, admired in the schools; *Milton*, celebrated among the poets; and *Washington*, immortal in the field and the cabinet. To this catalogue of professing christians, may now be superadded the name of Alexander Hamilton—a name which raises in the mind the idea of whatever is splendid, whatever is illustrious in human nature; and which is now joined to a catalogue which might be lengthened—and lengthened—and lengthened, with the names of illustrious characters, whose lives have blessed society, and whose works form a column high as heaven—a column of learning, of wisdom, and of greatness, which will stand to future ages, an *eternal monument* of the transcendent talents of the advocates of christianity, when every fugitive leaf, from the pen of the canting infidel writings of the day, shall be swept by the tide of time from the annals of the world, and buried with the names of their authors in oblivion.

To such as have only a superficial knowledge of the character and services of the late general Hamilton, the extraordinary grief manifested by the public, on his death, would appear excessive. They may say, the United States have produced many great men. Some preceded him to the tomb; and others yet live. Why then should his departure be mourned, as if it were not a lot to be expected? Why did, and why do still, the American people mourn his fall, as if all were lost? Although general Hamilton had, for some years, withdrawn from public office to the bar, and had been, in some measure, out of the view and contemplation of his countrymen, there was nevertheless a splendour in his character, that could not be contracted within the ordinary sphere of his employments. With really great men it is as with great literary works: the excellence of both is tested by the extent and durableness of their impression. The public has not suddenly, but after an experience of five and twenty years, taken that impression of the just celebrity of general Hamilton, which nothing but his extraordinary intrinsic merit could have made, and still less could have made so deep, and maintained so long. It was not a party; for party distinctions were confounded by the event; it was the nation that wept for its bereavement. It wept as the Romans did over the ashes of Germanicus. Its sorrow was thoughtful, foreboding, took possession of the heart, and sunk with no counterfeited heaviness.

It is here proper, and not invidious, to remark, that as emulation, excited by conducting great affairs, commonly trains and exhibits great talents, it is seldom the case, that the fairest and soundest judgment of a great man's merit, is to be gained, exclusively, from his associates in council or action. Persons of conspicuous merit themselves are, not unfrequently, bad judges, and still worse witnesses on this point. Often rivals, sometimes enemies, almost always unjust, and still oftener envious or cold, the opinions they give to the public, as well as those they privately form for themselves, are, of course, discoloured with the hue of their prejudices and resentments: but the body of the people, who cannot feel a spirit of rivalship towards those whom they see elevated by nature and education so far above their heads, are more equitable, and, supposing a competent time and opportunity for information on the subject, more intelligent judges. Even party rancour, eager to maim the living, scorns to strip the slain. The most hostile passions are soothed or baffled by the fall of their antagonist. Then, if not sooner, the very multitude will decide on character, according to their experience of its impression; and as long as virtue, not unfrequently for a time obscured, is ever respectable when distinctly seen, they cannot withhold, and they will not stint their admiration. If then the popular estimation may be taken for the true one, the uncommonly profound public sorrow for the death of Alexander Hamilton, sufficiently explains and vindicates itself. He had not made himself dear to the passions of the multitude, by condescending, in defiance of his honour and conscience, to become their instrument. He was not lamented, because a skilful flatterer lay mute for ever. It was by the practice of no art, by wearing no disguise; it was not by accident, nor by the levity nor profligacy of party; but, in despite of its malignant misrepresentation, it was by bold and inflexible adherence to truth, by loving his country better than himself, preferring its interest to its favour, and serving it, when it was unwilling and unthankful, in a manner that no other person could, that he rose; and the *true* popularity, the homage that is paid to virtue, followed him. It was not in the power of party or envy to pull him down: but he rose, as if some force of attraction drew him to the skies. He rose, and the very prejudice that could not reach, was at length almost ready to adore him.

It was indeed no imagined wound that inflicted so keen an anguish. For some time after his death, the novel and strange events of Europe succeeded each other unregarded. The nation was enchained to its subject, and brooded over its grief, which was more deep than eloquent; which, though dumb, made itself felt without utterance; and which did not merely pass, but, like an electrical shock, at the same instant smote and astonished, as it passed from Georgia to New Hampshire. There is a kind of force put upon our thoughts by this disaster, that detains and rivets them to a closer contemplation of those resplendent virtues which are now lost except to memory; and there will dwell forever. That writer would deserve the fame of a public benefactor, who could exhibit the character of general Hamilton with the truth and force that all, who intimately knew him, conceived it. His example would then take the same ascendant as his talents. The portrait alone, however exquisitely finished, could not inspire genius where it is not; but if the world should again have possession of so rare a gift, it might awaken it where it sleeps, as by a spark from heaven's own altar: for, surely, if there be any thing like divinity in man, it is in his admiration of virtue: but who alive can exhibit this portrait? If our age, on that supposition more fruitful than any other, had produced two Hamiltons, one of them might then have depicted the other. To delineate genius one must feel its power. Hamilton, and he alone, with all inspiration, could have transferred his whole fervid soul into the picture, and swelled its lineaments into life. The writer's mind, expanding with his own enthusiasm, and glowing with kindred fires, would then have stretched to the dimensions of his subject.

Such is the infirmity of human nature, it is very difficult for a man, who is greatly the superior of his associates, to preserve their friendship without abatement. Yet, though general Hamilton could not possibly conceal his superiority, he was so little inclined to display it, he was so much at case in its possession, that no jealousy or envy chilled his bosom when his friends obtained praise. He was, indeed, so entirely the friend of his friends; so magnanimous; so superior, or, more properly, so insensible to all exclusive selfishness of spirit; so frank; so ardent, yet so little overbearing; so much trusted, admired; beloved, almost adored; that his power over their affections was entire, and lasted through his life. It is not believed, that he left any worthy man his foe, who had ever been his friend. Men of the most elevated minds have not always the readiest discernment of character. Perhaps he was sometimes too sudden and too lavish in bestowing his confidence. His manly spirit, disdaining artifice, suspected none; but while the power of his friends over him seemed to have no limits, and really had none, in respect to those things which were of a nature to be yielded, no man, not the Roman Cato himself, was more inflexible on every point that touched, or only seemed to touch, integrity and honour. With him, it was not enough to be unsuspected. His bosom would have glowed like a furnace at its own whispers of reproach. Mere purity would have seemed to him below praise; and such were his habits, and such his nature, that the pecuniary temptations, which many others can only with great exertion and self-denial resist, had no attractions for him. He was very far from obstinate. Yet, as his friends assailed his opinions with less profound thought than he had devoted to them, they were seldom shaken by discussion. He defended them, however, with as much mildness as force; and evinced that, if he did not yield, it was not for want of gentleness or modesty. His social affections, and his private virtues, are not, however, so properly the object of public attention, as the conspicuous and commanding qualities that gave him fame and influence in the world. It is not as Apollo, enchanting the shepherds with his lyre; it is as Hercules, treacherously slain, in the midst of his unfinished labours, leaving the world overrun with monsters, that he is most deeply deplored.

In all the different stations in which a life of active usefulness placed him, he was not more remarkably distinguished by the extent, than by the variety and versatility of his talents. In every place, he made it apparent, that no other man could have filled it so well; and, in times of critical importance, in which alone he desired employment, his services were justly deemed indispensable. As secretary of the treasury, his was the powerful spirit that presided over the chaos—

> Confusion heard his voice, and wild uproar
> Stood ruled—

Indeed in organizing the federal government in 1789, every man of either sense or candour will allow, the difficulty seemed greater than the first rate abilities could surmount. The event has shown that his abilities were greater than those difficulties. He surmounted them, and Washington's administration was the most wise and beneficent, the most prosperous, and ought to be the most popular, that ever was entrusted with the affairs of a nation. Great as was Washington's merit, much of it in plan, much in execution, was due to the talents, and ought to enhance the memory of his minister. As a lawyer, his comprehensive genius reached the principles of his profession. He compassed its extent; and fathomed its profound, perhaps even more familiarly and easily, than the ordinary rules of its practice. With most men, law is a trade. With him it was a science. As a statesman, he was not more distinguished by the great extent of his views, than by the caution with which he provided against impediments, and the watchfulness of his care, over right, and the liberty of the subject. In none of the many revenue bills which he framed, though committees reported them, is there to be found a single clause that savours of despotic power; not one that the sagest champions of law and liberty would, on that ground, hesitate to approve and adopt.

It is rare that a man who owes so much to nature descends to seek more from industry: but he seemed to depend on industry, as if nature had done nothing for him. His habits of investigation were very remarkable: his mind seemed to cling to his subject, till he had exhausted it. Hence the uncommon superiority of his reasoning powers; a superiority that seemed to be augmented from every source; and to be fortified by every auxiliary; learning, taste, wit, imagination, and eloquence. These were embellished and enforced by his temper and manners; by his fame and his virtues. It is difficult, in the midst of such various excellence, to say in what particular the effect of his greatness was most manifest. No man more promptly discerned truth. No man more clearly displayed it. It was not merely made visible. It seemed to come bright with illumination from his lips. But prompt and clear as he was; fervid as Demosthenes; like Cicero, full of resource; he was not less remarkable for the copiousness and completeness of his argument, that left little for cavil, and nothing for doubt. Some men take their strongest argument as a weapon, and use no other: but he left nothing to be inquired for more; nothing to be answered. He not only disarmed his adversaries of their pretexts and objections; but he stripped them of all excuse for having urged them. He confounded and subdued, as well as convinced. He indemnified them, however, by making his discussion a complete map of his subject; so that his opponents might indeed feel ashamed of their mistakes: but they could not repeat them. In fact, it was no common effort, that could preserve a really able antagonist from becoming his convert. For, the truth, which his researches so distinctly presented to the understanding of others, was rendered almost irresistibly commanding and impressive, by the love and reverence which, it was ever apparent, he profoundly cherished for it in his own. While patriotism glowed in his heart, wisdom blended, in his speech, her authority with her charms. Such also is the character of his writings. Judiciously collected, they will be a public treasure.

No man ever more disdained duplicity, or carried *frankness* further than he. This gave to his political opponents some temporary advantages; and currency to some popular prejudices, which he would have *lived* down, if his death had not prematurely dispelled them. He knew that factions have ever in the end prevailed in free states; and as he saw no security, and who living can see any adequate? against the destruction of that liberty which he loved, and for which he was ever ready to devote his life, he spoke at all times according to his anxious forebodings, and his enemies interpreted all that he had said, according to the supposed interest of their party. But he ever extorted confidence, even when he most provoked opposition. It was impossible to deny that he was a patriot. Virtue so rare, so pure, so bold, by its very purity and excellence, inspired suspicion, as a prodigy. His enemies judged of him by themselves. So splendid and arduous were his services, they could not find it in *their* hearts to believe that they were disinterested. Unparalleled as they were, they were nevertheless no otherwise requited than by the applause of all good men, and by his own enjoyment of the spectacle of that national prosperity and consideration, which was the effect of them. After facing calumny, and triumphantly surmounting an unrelenting persecution, he retired from office with clean, though empty hands, and as rich as reputation and an unblemished integrity could make him. Some have plausibly, though erroneously inferred, from the great extent of his abilities, that his ambition was inordinate. This is a mistake. Such men as have a painful consciousness that their stations happen to be far more exalted than their talents are generally the most ambitious. General Hamilton, on the contrary, though he had many competitors, had no rivals; for he did not thirst for power; nor would he, as it was well known, descend to office. Of course he suffered no pain from envy when bad men rose; though he felt anxiety for the public. He was perfectly content and at ease in private life. Of what was he ambitious? Not of wealth. No man held it cheaper. Was it of popularity? That weed of the dunghill, he knew, when rankest, was nearest to withering. There is no doubt, that, being conscious of his powers, he desired glory, which to most men is too inaccessible to be an object of desire. But feeling his own force, and that he was tall enough to reach the top of Pindus or of Helicon, he longed to deck his brow with the wreath of immortality. A vulgar ambition could as little comprehend as satisfy his views. He thirsted only for that fame that virtue would not blush to confer; nor time to convey to the end of his course. The only ordinary distinction to which we confess he did aspire was military; and for that, in the event of a foreign war, he would have been solicitous. He undoubtedly discovered the predominance of a soldier's feelings; and all that is honour, in the character of a soldier, was at home in his heart. His early education was in the camp. There he became enamoured of glory, and was admitted to its embrace. Those who knew him best, and especially in the army, will believe, that if occasion had called him forth, he was qualified, beyond any man of the age, to display the talents of a great general.

The most substantial glory of a country is in its virtuous great men. Its prosperity will depend on its docility to learn from their example. That nation is fated to ignominy and servitude, for which such men have lived in vain. Power may be seized by a nation that is yet barbarous, and wealth may be enjoyed by one that it finds or renders sordid. The one is the gift and the sport of accident, and the other is the sport of power. Both are mutable, and have passed away, without leaving behind them any other memorial, than ruins that offend taste, and traditions that baffle conjecture. But the glory of Greece is imperishable, or will last as long as learning itself, which is its monument. It strikes an everlasting root, and bears perennial blossoms on its grave. The name of Hamilton would not have dishonoured Greece in the age of Aristides. See *Mason's Oration; Nott's Sermon; Morris's Funeral Oration; Otis's Eulogy; Ames's Sketch; Coleman's Collections, Ramsey's Hist. U. S. &c.*—(E. H. Cummins, A. M.)

---

HAMILTON, the chief town of the middle ward of Lanarkshire, is about 12 miles to the south-east of Glasgow, and situated in the parish of the same name. In ancient times, the district in the neighbourhood of Hamilton appears to have borne the designation of *Cadzow*, while the town seems to have been called "the Orchard," probably from the fruit-grounds with which the houses were surrounded. There is little doubt that the town derives its present appellation from the noble family of Hamilton, who appear to have settled in Clydesdale soon after the year 1215.

The first residence of the family was Cadzow Castle, situated on the precipitous banks of the Avon, about a mile from the town. In the statistical account of Hamilton, it is mentioned, that this building was deserted after the injuries it sustained from the army of the regent Murray, but a considerable portion of it is still to be seen, denoting the massy strength of the original structure. The palace of Hamilton, now occupied, (A. D. 1816,) by the most noble the Marquis of Douglas, as representative of his father the Duke of Hamilton, is situated in the higher part of the beautiful and fertile valley through which the Clyde pursues its course, and lies to the west of the confluence of that noble river with the Avon. It was built about the end of the 17th century, and forms three sides of a quadrangle. The apartments are large and lofty, and have lately been very splendidly fitted up. The gallery of paintings is perhaps the finest in Scotland, many additions having been made to it by the present Marquis of Douglas. The portrait of the Earl of Denbeigh by Vandyke, and "Daniel in the Den of Lions," by Rubens, have been noticed by every traveller. To these may be added, a St Sebastian by Guido Reni, a St Francis, and infant St John, by Correggio, and in particular an "Ecce Homo," by the same master. Two landscapes of rocks, and a head of Diogenes by Salvator Rosa, a dying Madona by Ludovico Caracci, and an admirable painting of the Virgin embracing the head of Christ, by Mabeuge. In the great gallery there is likewise a bust of Cleopatra, in which the depth and aggravation of grief are most wonderfully expressed; and in one of the lower apartments there is a statue of "the Venus de Medici." Among the valuable curiosities, we have observed a large table of the most beautiful *malachite*, unequalled, as far as we have been able to learn, in any part of the British empire.

Nearly opposite to Cadzow upon the Avon, and in full view of the palace, stands the castle of Chatelherault, built by the Duke of Hamilton in the year 1730, and meant to represent the castle of the same name in France, of which his ancestors were dukes. It was executed from a design of the elder Adams. In the surrounding park are some of the largest oaks in Scotland, the remains of those extensive forests with which the country was formerly covered. Among these trees grazed the ancient Caledonian cows, mentioned by Hector Boece, as a peculiar breed, and distinguished by their manes resembling those of lions, by their snowy whiteness, and their untameable ferocity. It is believed that the original race are now extinct; for the present breed are not remarkably different in their appearance from the common cow, excepting only that they are all over white, or rather cream-coloured, and have black or brown ears and muzzles. They may be approached without fear or difficulty.

By the exertions of the Marquis of Douglas, the palace is now wholly separated from the town. The latter consists of a main street, running in a south-eastern direction, and forming part of the road from Glasgow to Lanark. There are many cross streets, and individual houses with gardens attached to them. The prison and town-hall are in the centre of the town, and on the former there is a tolerable spire. The parish church was built in 1732, from a design of Adams. It stands upon a rising ground in the upper part of the town, and is a very handsome structure, uniting stability with lightness. Though by no means well seated, it is understood to accommodate about 1300 people. The charge is collegiate, but the stipends of the ministers have lately been equalized. Besides the parish church, there is one belonging to the Relief Seceders, another to the Burghers, and a third to the Antiburghers. The schools are numerous. There is a large hall for a grammar school. It was in this school that the celebrated Dr William Cullen, the father of physic in Scotland, received a part of his education; and the traditionary report of the townsmen bears, that he appeared at one of the annual examinations in girl's clothes, acting the part of a shepherdess, in a Latin pastoral. Nor ought we to omit, that Dr Baillie of London, and the late Mr John Millar, professor of law in the university of Glasgow, are indebted for a portion of their fame, to the instructions they received in the schools of Hamilton.

The town is what is called a burgh of regality; but the appointment of the magistrates rests entirely with the family of Hamilton. It is governed by a first and second magistrate, with the assistance of a town-council, treasurer, and clerk. The population of the town was, in 1753, 3815; in 1792, 5017; and it is now above 7000 souls. Some years ago a subscription library was established in Hamilton, owing principally to the zealous exertions of Dr John Hume. The library is under the direction of a committee of management, who are chosen annually; and the collection of books is multifarious and valuable. (*h*)

HAMMERSMITH. See Middlesex.

HAMPDEN. See Britain.

HAMPSHIRE, Hants, or the *County of Southampton*, is a maritime county, situated on the southern coast of England. It is bounded on the north by Berkshire; on the east by Sussex and Surrey; on the south by the English Channel, and the sound, which separates it from that part of the county called the Isle of Wight; and on the west by Dorsetshire. Its limits on the south side are the numerous creeks and inlets formed by the sea; on the west and east they are mostly artificial; on the north they are chiefly composed by the rivers Enborsa and Blackwater. The figure of Hampshire is nearly that of a square, with a triangular projection at the south-west angle, resembling the bastion of a fortification. Besides the Isle of Wight, the islands of Jersey and Guernsey are included as parts of the county: its length, exclusive of the projection of the south-west and the Isle of Wight, is about 42 miles, and its breadth about 38.

Hampshire is divided into 52 hundreds and liberties; these are subdivided into 356 parishes, precincts, hamlets, and tythings, the parishes alone being 253. In it there is one city, Winchester, which is also the county town, though Southampton is sometimes regarded in that light. Besides Winchester and Southampton, there are 18 other market towns, of which the principal are Portsmouth, Andover, Lymington, Christchurch, Basingstoke, Alton, Fareham, and Romsey. Winchester, Southampton, Portsmouth, Andover, Lymington, Christchurch, Stockbridge, Whitchurch, and Petersfield, send each two members to parliament, so that the county sends in all twenty members to parliament, exclusive of those sent by the Isle of Wight: it pays 14 parts of the land-tax. Hampshire lies in the province of Canterbury, and diocese of Winchester, and, with the county of the town of Southampton, is included in the western circuit.

This county is justly regarded as one of the most agreeable in England, being equally distinguished for the goodness of its soil, the healthiness and mildness of its climate, and the beauty of its prospects. The surface is finely varied with hills of gentle elevation and fruitful vallies, adorned with numerous gentlemen's seats and villages, and interspersed with numerous woodlands. Its southern parts were the first peopled, and there the population is still the greatest; the mildness of the seasons, and the convenience of the ports, operating as strong inducements to continued residence. The ridge of chalk hills may be traced across the county, passing in the parallel of Winchester. The climate in the higher parts is bracing and healthy, from the clearness and pureness of the air; towards the sea, it is mild, and rather moist.

The soil of Hampshire is extremely various, though, for the most part, of a calcareous nature. On the borders of Berkshire, it is deep, of a good quality, and very productive of corn and timber, particularly oak and elm. On the acclivities of the hills towards Basingstoke, it is also very deep and strong, with a calcareous subsoil. Round Whitchurch it is less deep and chalky. From Overton towards Stockbridge, and thence to Redbridge, there is a beautiful vale, which is divided into well-watered meadows. Round Andover the land is high, and approaches to the nature of downs. Towards Romsey it is more fertile. The country here is very beautiful, being interspersed with woods, and fine hedge-row timber. The centre of the county, in general, may be described as consisting of land higher and more chalky than the rest of the county, but by no means of an unfertile soil. On the borders of Dorsetshire, are vast tracts of waste land covered with heath. The vicinity of Redbridge is distinguished for its valuable salt marshes. Down land is met with between Petersfield and Portsmouth. On the banks of the Itchin, are some valuable water meadows. Perhaps the richest and most valuable soil in this county is near Alton.

The principal rivers in Hampshire, are the Itchin, the Avon, the Boldre Water, the Exe, the Anton, and the Tesse, or Test. Several smaller streams rise in the north-west parts of the county, but these soon quit it in their course to the Thames. The Itchin rises near Alresford, near the centre of the county; and after passing Winchester, it unites its streams with the water of Southampton, about half a mile to the east of that town. The Avon enters the county from Wiltshire, near Fordingbridge, and coasts the edge of the New Forest. This part of its course is thus not only well wooded, but enlivened by the numerous villas that ornament its banks. After passing Ringwood, it flows through a less interesting sandy level towards Christchurch. Below this town, it receives the waters of the Stour from Dorsetshire, and with them falls into Christchurch bay. The Boldre Water is formed by various springs rising in the New Forest, which uniting, pass Boldre and Lymington to the sea. The Exe also rises in the same district, and opens in a broad estuary to the sea, below Exbury. The Anton rises in the north-west angle of the county, and flowing through Andover, runs into the Tesse about a mile below Whirwell. The Tesse has its origin below Whitchurch; and after its junction with the Anton assumes a southerly course, and passing Stockbridge and Romsay, receives several small streams from the New Forest, near Redbridge. Below this place it expands considerably, and forms the head of Southampton Water. This, properly speaking, is an arm of the sea, extending from above Southampton to Caldshot Castle, and rendered very picturesque by its woody and irregular banks. Its whole extent is nearly 10 miles. Near Southampton, it is about four miles broad. It is navigable almost to the head for vessels of considerable burden; and the two principal rivers which flow into it, admit small craft some way up into the county. On tracing the sea coast from the east, we come to Portsea island, a low tract of considerable extent, separated from the main by a shallow creek, over which a bridge is built. On this island Portsmouth is situated. Off the point of land terminating this peninsula, is the noted road of Spithead, where the men of war anchor when prepared for actual service. From this, on the east side, commences Trissanton Bay, or Southampton Water.

There are very few mineral substances found in this county. On the southern shores, iron-stone was formerly gathered in some quantity, which seems to have been rolled up by the surf. Between Milton and Christchurch a hard reddish stone is found, apparently calcareous, tinged with the oxide of iron. Several ancient structures in the county are built with it. Chalk of various qualities and colours is worked in different parts. Potter's clay is met with in great abundance in Poolheath, at various depths, from 10 to 20 feet. From the circumstance of this heath bearing all the external marks by which the heath of Purbeck is distinguished, and their being divided only by Pool Water, it is not improbable that the Hampshire clay will be found equally valuable and useful as the Purbeck.

Hampshire is distinguished as an agricultural county for its fine corn, especially wheat; its hops, cattle, sheep, wool, bacon, honey, timber, and the extent and excellent management of its water meadows. The largest estates and farms are in the chalky parts of the county. The largest estate, however, does not exceed 8000*l.* per annum. Tenures are various. Those estates, which formerly composed the demesne lands of the see of Winchester, are granted by the bishop as freeholds for three lives, and generally renewed to the families, who hold them for many generations. These estates consist chiefly of ancient manors and houses, to which certain feudal rights still appertain. Copyhold tenures are granted from manors vested in the church, or by the lay proprietors. There are also lands held on lives by lease, or indenture. Other leases are for 21 and 14 years; but here, as in other parts of England, the practice is extending of letting lands only at will. The average size of farms in the county is small, probably not exceeding 200 acres; and certainly, if the chalk districts are excluded, not reaching that extent. The ploughs are various; but principally with one or two wheels, and by no means constructed on good mechanical priciples. There are a few thrashing machines in the county. The chief part of Hampshire is inclosed, though large tracts of open heath and uncultivated land remain in the vicinity of Christchurch, and on the borders of Dorsetshire. The aggregate extent of the waste lands, exclusive of the forests, is supposed to amount to nearly 100,000 acres.

In Hampshire a considerable quantity of land is annually sown with wheat, which is cultivated with great skill; its quality is excellent. Barley is grown principally on the lighter soils and higher ground. The soil round Andover is very favourable to the growth of this grain. It is generally sown either after turnips, or a winter fallow. In the cultivation of oats, the Hampshire farmers do not display much agricultural skill, since, for the most part, they are sown after one or two white crops. B ans are not much cultivated, even upon soils well adapted to them. The white pea is grown to a considerable extent in various parts of the county; the cultivation is well understood; and the produce abundant and valuable. Turnips are extending; but their culture is not yet nearly so general as it might, or ought to be; nor is it well understood. Potatoes are grown in almost every part, on a good plan, and with abundant produce. The utility and value of the calcareous soils in Hampshire are very much increased by the growth of sainfoin on them. This plant seems to have been long known here, and its culture is well understood. The parishes to the east of Alton, on the borders of Surrey, are chiefly appropriated to the growth of hops, the plantations of which have been greatly increased lately, chiefly in consequence of the high character of the hops grown at Farnham, in the immediate vicinity of Alton; the Hampshire hops, in a great degree, partaking of this character. The hop grounds are supposed to occupy 800 acres. The water meadows, as has already been noticed, are numerous, extensive, and extremely well managed. They are made at first at the expence of 5*l.* or 6*l.* per acre; and the expence of continual repairs is very considerable. But they pay the farmer well. They are usually shut up in November, or the beginning of December; and are watered every alternate week, till the beginning of March, when they are pastured for about five or six weeks with ewes and lambs. An acre is considered equal to the feeding of 400 couples for one day. They are shut up about the beginning of May, and produce at the regular season an abundant crop of hay. Perhaps the largest and finest tract of water meadows in the county lies on the banks of the Itchin, extending from the north side of Winchester, through Twyford and Otterburne, towards Bishops Stoke.

Gardening is carried to a considerable extent in the neighbourhood of all the large towns: Portsea island is supposed to produce the finest broccoli in the kingdom. Orchards are not common or productive in the woodland or chalky districts; but on the marly and clay soils, in the south and south-western parts of the county, they are more common; even here, however, little or no cyder is made for sale, the farmer contenting himself with making two or three hogsheads annually for the use of his family. A considerable portion of Hampshire is occupied by the forest of Alice Holt and Walmer, the forest of Bare, and the New Forest: the first is divided into two portions by intervening private property, one part containing 15,493 acres, and the other 2.744 This forest is situated on the borders of Surrey and Sussex. The forest of Bare extends northward from the Portsdown hills, including about 16,000 acres. The ancient boundaries of the New Forest included the whole of that part of Hampshire which lies between Southampton water on the east, the British Channel on the south, and the river Avon on the West. By a perambulation on the 22d of Charles II. it was ascertained that it extended from Godshill on the north-west to the sea, on the south-east about 20 miles, and from Hardley on the east to Ringwood on the west about 15 miles, containing within those limits 92.365 acres: of these 24.797 belong to individuals; 901 acres are encroachments; 1192 are inclosed land in the possession of the master, keepers, &c.; and the remainder, being about 63,845 acres, constitute the woods and waste lands of the forest. Its officers are, a lord warden, a lieutenant, riding forester, bow bearer, two rangers, woodward, under woodward, four verderers, high steward, under steward, 12 regarders, 9 foresters, or master keepers, and usually under foresters. The quantity of timber supplied by this forest for naval purposes from 1761 to 1786 was 23,000 loads of oak, and 7003 loads of beech; and the number of deer killed annually is about 76 brace of bucks, and 17 brace of does. The timber was so very much neglected, that, in the year 1800, an act of parliament was passed for its increase and preservation. The scenery of the New Forest affords as great a variety of beautiful and picturesque landscape, as can be met with in any part of England, of the same extent. The oaks seldom rise into lofty stems, but their branches are adapted for knee timber, and are commonly twisted into the most picturesque forms. The Cadenham oak is regarded as one of the curiosities of the forest, the buds appearing every year in the depth of winter. The advantages which this forest derives from its situation, in respect to conveniency of water carriage, are superior to those of any other forest in England; in its vicinity are many places for shipping timber, amongst which are Lymington, Beaulieu, and Redbridge, with the additional advantage of the remotest of those places being little more than 30 miles from the dock-yard of Portsmouth. Hampshire is remarkable for the great quantity and excellent quality of its oak bark, supplied chiefly by the timber in the New Forest.

Hampshire does not possess any peculiar or specific breed of cattle; the Sussex, Suffolk, Hereford, Glamorgan, and North and South Devon, are chiefly employed for draught, and the Norman for the dairy. Cows kept for the latter purpose are rented out to dairymen at from 7*l.* to 9*l.* per cow, per annum. In the woodland district of the county, the heath sheep are sometimes met with; but the most common in other parts are the Old Hampshire, something resembling the Dorsetshire in their size, shape, and qualities, and the New Leicester. The Wiltshire and Dorsetshire are also kept for the purpose of house lamb. On the Downs, the South Down sheep are spreading fast. Hampshire has long been justly celebrated for the excellency of its bacon. The native hog of the county is a coarse, ill-fattening animal, from which neither much nor good bacon would be expected; but the mart, and other food which the forests produce, and the excellent mode of curing in practice, have contributed, in a far greater degree, to establish the superiority of Hampshire bacon, than any inherent excellence in its native breed of hogs. These, however, have been greatly improved in form and quality, by crosses with the Berkshire, Suffolk, and Chinese breed.

In this county, there are three distinct series of canals, two of which terminate in the water of Southampton. The north-western part of the county has also been much benefited by the Kennet navigation, leading from Newberry to Reading. The Basingstoke canal commences at that town, and falls into the river Wey near the village of Westley; it is something more than 37 miles in length, with a fall of 195 feet. The Andover and Redbridge canal begins near the former place, and falls into the Southampton water near the latter. Its length is 22½ miles; its fall, 176 feet 9 inches. A collateral branch is navigable to within 2 miles of Salisbury. The Winchester and Southampton canal is one of the most ancient in the kingdom. The act for making it was obtained in the reign of Charles I. There are several fish-ponds in Hampshire, particularly on the wet soils on the borders of Surry. These ponds are usually stocked with carp and tench; and, in favourable circumstances, five acres of water will support 1250 brace of these fish, until the stock are fit for market, and have obtained an average size of 2 lb. per brace, and consequently weigh 2500 lb.; which, at 9d. per lb. the price at which they are usually sold to the London fishmongers, will amount to 93l. 15s. the value of five acres of land so employed for three years.

The manufactures of Hampshire are not very considerable or numerous. At Alton, there are manufactures of serges, and a variety of worsted articles, bombazines, &c. Worsted yarn is spun in this town and neighbourhood. Nearly the same kind of manufactures exist at Alresford. Basingstoke is distinguished for its manufactures of malt and leather. At Overton there is a silk mill of considerable magnitude; and in this part of the county the young female peasantry are much employed in making straw hats. The paper mills near Overton are famous for being employed in making paper for the notes of the Bank of England. There are also paper mills in other parts of Hampshire. Andover is remarkable for the large quantities, as well as for the excellent quality, of the malt made in it and the vicinity. Its former manufacture of shalloons is on the decay. A considerable quantity of yarn and worsted is spun in this part for the manufactures at Salisbury. Stockbridge is noted for wheelwrights and carpenters. In Winchester, many people are employed in the manufacture of light silk goods, and in preparing and winding the silk. The manufactured goods are principally used for umbrellas. Romsey is famous for its beer; the manufacture of shalloons is greatly decayed; considerable quantities of sacking are made. At Fordingbridge, there is an extensive and flourishing manufacture of striped bed ticking; nearly two-thirds of the inhabitants being employed in spinning, bleaching, weaving, &c. for this manufacture. Knit silk stockings, and a watch chain manufactory, particularly distinguish Christchurch. At Lymington there are very extensive and valuable manufactures of culinary and medicinal salts from sea-water. Southampton was formerly famous for its trade in French and port wines; but this is in a great measure gone to decay. At Farnham, there are manufactures of bricks, tiles, chimney pots, and sacking and cordage. There is one fair in Hampshire which deserves particular notice. This is held at Wey-hill, in the hundred of Andover. It commences the day before Michaelmas-day, and is one of the largest in the kingdom for hops, sheep, and cheese. Upwards of 140,000 sheep have been sold in one day. The Farnham hops are almost entirely sold here. The fair generally lasts 6 or 7 days.

The Isle of Wight must be particularly noticed. It is separated from the main land of the county by a channel varying from 2 to 7 miles in breadth. Its form is that of an irregular lozenge. It is nearly divided into two equal parts by the river of Corves. Through the middle of it, in the longest direction, extends a range of downs. The eastern and western parts of the island are almost cut off from the body by arms of the sea. Its length from east to west is about 22 miles; its breadth 13 miles; its circumference about 70. It contains 105,000 acres, of which 75,000 are in a course of tillage, 20,000 in pasturage, and the remainder downs and waste. It is divided into two hundreds, one market town, Newport, and 3 boroughs, returning each two members, Newton, Newport, and Yarmouth. The other towns of consequence are Corves and Ryde. It contains 30 parishes. The face of the country is very diversified. The land round the coast being in some places very high, particularly on the south or back of the island, where there are steep cliffs of chalk and freestone, hollowed out into caverns. On the north side the ground slopes to the water in easy declivities. The western side is fenced with ridges of rocks, of which the most remarkable are those called, from their sharp extremities, the Needles. The height of the cliffs in the north-west is, in some places, 600 feet above the level of the sea. They are frequented by immense numbers of marine birds. Between the island and the main-land are various sand banks, especially off the eastern part, where is the safe road of St Helens.

The land to the north of the ridge already mentioned, is chiefly pasture. To the south of it is a rich arable country, producing great crops of corn. It is said that the grain annually grown here is sometimes greater than the consumption of the island. The farms are small. The crops usually obtained are wheat, barley, oats, beans, turnips, clover, &c.; the prevalent soil, a strong loam on a dry subsoil, being well calculated for all these crops. The butter made here is excellent: the cheese, the worst in England except the Suffolk. The cattle are the Devonshire and Alderney; the sheep mostly Southdown and Dorset. On the downs a great number of fine-fleeced sheep are fed, about 40,000 being annually shorn, and about 5000 lambs sold. Rabbits are very plentiful. The climate is almost proverbially mild; and as the scenery is scarcely equalled in any part of Europe, this isle is a favourite residence. There are not many woods. The most extensive are those of Swainston, Wooten, and Quarr. The chief rivers are, the Medina, the Yar, and the Wooten. The Medina, passing Newport, falls into the sea at Corves: the Yar falls into the channel at Yarmouth: the Wooten falls into Braden's harbour. There are also various creeks and bays. Great variety of fish is found on the coast, particularly lobsters and crabs. The cockles are much celebrated, and the sandeel is very plentiful.

Among the products of this island are to be reckoned a pure white pipe-clay, and a fine white crystalline sand. Great quantities of the latter are exported for the use of the glass-works. Alum formerly was manufactured in some of the western coves of the island.

By the returns respecting the poor-rates in the year 1803, it appears, that in the whole county, including the isle of Wight, 153,427*l.* was annually raised for poor and other rates. The average rate in the pound on the rack-rental was 4*s.* 5¼*d.* 130,983*l.* was actually expended on account of the poor. The number of friendly societies was 62, containing 4733 members. The number of children in schools of industry amounted to 614. In the year ending 25th March 1815, the sum raised in this county for poor and other parochial rates amounted to 211,557*l.*, making an increase since 1803, or in the space of 12 years, of 58,130*l.*, or nearly 30 per cent.

At the invasion of the Romans, great part of Hampshire was possessed by the Regni and Belgæ. The latter kept possession of it for 60 years after the first landing of the Saxons; afterwards it formed part of Wessex. The most remarkable antiquities in the county are, Netley Abbey, near Southampton, founded in the year 1239. The ruins of this abbey, situated as they are on the declivity of a hill, rising gently from the water, and environed by most beautiful wood scenery, form a very interesting object. The cathedral of Winchester, curious as an instructive example of architecture; the chapel of our Lady, the choir, and a magnificently carved screen in stone work, are particularly celebrated. The college of William of Wykeham, at Winchester, is also a remarkable building, independently of their character and utility as a seminary. Hurst and Carisbrooke castles, the latter in the isle of Wight, are remarkable for having been the prisons of Charles I.

The following results, respecting the population of this county, appear from the returns made in the year 1811:

| | |
|---|---|
| Houses inhabited | 43,210 |
| Families occupying them | 50,916 |
| Houses building | 441 |
| ——— uninhabited | 1030 |
| Families employed in agriculture | 21,401 |
| ——— manufactures, &c. | 18,024 |
| ———-not comprised in these classes | 11,481 |
| Males | 118,855 |
| Females | 126,225 |
| Total, | 245,080 |
| Population in 1801 | 226,900 |
| Increase | 38,180 |

---

HAMPSHIRE, New, one of the United States of America, is bounded on the north by Lower Canada; on the east by Maine and the Atlantic; on the south by Massachusetts; and west by the Connecticut river. It lies between lat. 42° 41′, and 45° 11′, N. and between lon. 70° 40′, and 72° 28′, W. Its length is 168 miles: Its breadth, bounding on Massachusetts, is 90, and on Canada 19 miles. On the eastern boundary it has about 18 miles of sea coast. The state is divided into six counties: viz. Coos, Grafton, Cheshire, Hillsborough, Rockingham, and Strafford. These are again divided into two hundred and thirteen towns. The first settlement made in New Hampshire, was at the mouth of Piscataqua, in 1623. In the same year, Dover, eight miles higher up the river, was established. Several germs of settlements were subsequently planted along the coast. The several towns preserved a friendly intercourse with each other, in their respective employments of fishing, trading, and planting; and each governed itself until the year 1641, when they voluntarily came under the government of Massachusetts. This union subsisted nearly forty years: but, in 1679, the report of certain commissioners, appointed by the British government to enquire into, and determine a controversy between the successors of Sir Ferdinando Georges and Captain John Mason, and the colony of Massachusetts, being unfavourable to the latter, a separation took place; and a new and distinct government for New Hampshire was instituted. A governor and council of royal appointment, and an assembly, representing the people, were constituted the ruling power; and the new government went immediately into operation. In the year 1680, Mason, a grandson of Captain John Mason, arrived from England, with a mandamus, requiring the council to admit him to a seat at the board. He soon entered on his real errand; endeavouring to persuade some of the people to take leases of him; threatening others if they did not; forbidding them to cut firewood and timber; asserting his right to the province; and assuming the title of lord proprietor. His agents rendered themselves obnoxious, by demanding rents of the people, and threatening to sell their houses for payment. These proceedings raised a general tumult. Petitions were sent from each town, and from many individuals, to the council for protection; who, taking up the matter judicially, published an order, forbidding Mason or his agents, at their peril, to repeat their proceedings. The controversy between Mason and the council became so serious, that he deemed it expedient to quit the colony, and return to England. On his representations and solicitation, Edward Cranfield was commissioned lieutenant governor and commander in chief of New Hampshire; with power to call, adjourn, prorogue, and dissolve general courts; to have a negative voice in all acts of government; to suspend any of the council, who in consequence thereof would be rendered ineligible as representatives of the people; to appoint a deputy governor, judges, justices, and other officers; and to execute the powers of vice-admiral. The government was administered so flagitiously by Cranfield, that his authority was openly resisted by the people ; and he at length left New Hampshire and proceeded to Barbadoes. Towards the close of the reign of Charles the second, the charter of New Hampshire was merged in a commission issued to Joseph Dudley, appointing him president of his majesty's territory and dominion of New England; William Staughton, deputy president; and twelve others, counsellors. Their jurisdiction extended over Massachusetts, New Hampshire, Maine, and the Naraganset. In 1686, a commission issued to Sir Edmund Andross, appointing him captain general and governor in chief of the same territory, including also the colony of Plymouth. In 1689, in consequence of the tyranny of Andross's government, a revolution took place at Boston ; and the people there revived the government as it existed before the commission of Dudley. The people of New Hampshire supported the revolution, united once more voluntarily with Massachusetts, and continued this relation for three years. The consolidation, however, was not sanctioned by the crown ; but the old governments were restored.

Between the year 1692 and the American revolution there was a succession of fifteen governors in New Hampshire. The colony, in the meanwhile, was involved in war with the French and the contiguous Indian tribes. About the year 1719, it received a very considerable accession of inhabitants, by the emigration of one hundred families from the north of Ireland. They brought with them the necessary implements, and introduced the manufacture of linen. Their spinning wheels, turned by the feet, were a great novelty in the country. They also introduced the culture of the potatoe. The most of the emigrants settled in a town by themselves, which they called Londonderry, from that in Ireland, near which they had mostly resided. During its colonial state, New Hampshire suffered much by Indian hostilities. It was at one time so much harrassed, the population so much reduced, and subsistence so scanty, that the province was near being abandoned. The conquest of Canada, at length, gave peace to the frontiers of New Hampshire ; and the colony continued thenceforward to prosper beyond every calculation. It entered into the general revolution, in 1775, with a population of 82,200. It was well prepared to share in the struggle for national liberty. Its yeomanry were brave, hardy, capable of enduring fatigue, had long been accustomed to the use of arms, and were complete woodsmen. Some of them had acquired a considerable stock of military experience in the previous wars, to the dangers and calamities of which they had been particularly exposed. After the declaration of independence, no part of the territory of New Hampshire was, at any time, the seat of war : but many of its inhabitants fought bravely, and bled freely in the common cause. Dr. Belknap, the founder of the Massachusetts Historical Society, published an excellent history of New Hampshire, which is brought down to the year 1792.

The principal denominations of Christians, in New Hampshire, are congregationalists and presbyterians. There are a few episcopalians, baptists, universalists, quakers, and two small societies of sandemanians and shakers.

According to the constitution adopted in 1792, the civil authority is vested in a governor and council, senate and house of representatives, and a judiciary. The governor is elected annually by the people ; and must be worth five hundred pounds. If there be no choice by the people, the legislature complete the election. The executive council consists of five members. The legislature is called "The General Court." Each branch has a negative on the other. The senate consists of thirteen members, elected from as many districts ; and must be worth each a freehold of two hundred pounds. Every town, having 150 rateable polls, sends one representative to the general court ; and is entitled to another for every additional 300 polls. The representative must be worth one hundred pounds. The judiciary is composed of a superior court, having four judges ; an inferior court in each county, having four judges ; a court of general sessions in each county, in which the justices of the peace preside ; a court of ordinary, holden monthly in each county, by one judge ; and justices courts. All judges hold their offices during good behaviour. The population of New Hampshire, in 1810, according to the federal census, was 214,460. This entitles it to six representatives, besides two senators, in the congress of the United States. The prosperity and growth of the state may be seen by the progress of its population in the period of sixty years, ending with 1810. The number in

| | | | |
|---|---|---|---|
| 1749 was | 30,000 | 1790 was | 141,885 |
| 1767 | 52 700 | 1800 | 183,858 |
| 1775 | 82,200 | 1810 | 214,460 |

All able bodied males, between the ages of sixteen and forty-five, are liable to perform militia duty. These compose a force of about twenty thousand.

Literature, until in latter years, has not been so much cultivated in New Hampshire as in others of the New England states. In 1769, a college, which has recently been erected into an university, was founded, and liberally endowed. It was called Dartmouth, from William, earl of Dartmouth, one of its early and principal benefactors. The edifice stands on a plain, about the half of a mile from Connecticut river, in Hanover County. The rev. Dr. Wheelock, the son of the gentleman who was chiefly instrumental in procuring its charter, at his decease, in 1817, bestowed nearly 40,000 dollars upon the institution. Besides several liberal donations, the funds of the university consist in 80,000 acres of land, which now yield fifteen hundred dollars per annum ; but are daily becoming more productive. When properly tenanted, and judiciously managed, they will afford a handsome revenue. In 1812, there were in the institution a president, who is professor of civil and ecclesiastical history ; a professor of mathematics and natural philosophy ; a professor of languages ; and several tutors. There has also been erected a medical department, in which there are a professor of medicine, and a professor of chemistry. Until some recent feuds of a political and religious nature obstructed the administration, this institution flourished. At one time it had upwards of two hundred students within its walls, in the pursuit of science, who enjoyed the advantages of a valuable chemical and medical apparatus, and a library of 4000 volumes. Connected with the university of Dartmouth is Moore's charity school ; the funds of which, besides an edifice, consist of 12,000 acres of land, mostly in the state of Vermont ; and 11,000 dollars, vested by a society in Scotland for the education and religious instruction of the aborigines. This school has continued in operation nearly 65years ; and has been successful, to a great degree, in improving the manners and religion of several tribes of savages, within and near the boundaries of the United States. There are also several academies in the state. One at Exeter, called Phillips' Academy, was incorporated in 1781, is richly endowed, and has generally from 80 to 100 students. It is one of the best conducted seminaries in the United States. Every town is obliged by law to support one or more common schools. From the premises it will be seen, that science and literature have had liberal friends in New Hampshire.

Portsmouth is the largest town in the state. It is situated on the south bank of the Piscataqua, about two miles from its mouth; and has one of the finest harbours in the Union. A light-house, with a single light, stands at the entrance into the harbour. The population of Portsmouth, in 1810, was 6,934. The public edifices are three congregational churches, one Episcopalian, and one for Universalists; a state-house, a work-house, and two banks. Exeter stands at the head of navigation on the Swamscot; and contains a number of manufacturing establishments. There are in and about it a duck manufactory, six saw-mills, a fulling mill, slitting mill, paper mill, snuff mill, two chocolate and ten grist mills, two printing offices, and iron works. Saddles are manufactured extensively. Its public buildings are two congregational churches, an academy, court-house, and gaol; and its population in 1810 was 1,759. Concord, situated on the west bank of the Merrimac, is a flourishing town; and has between two and three thousand inhabitants. Charlestown on the Connecticut is a pleasant town, with a population of nearly 2000. Dartmouth in Hanover, thirty-six miles above Charlestown, is handsomely built, containing a church, chapel, academy, university, and 2,500 inhabitants. Haverhill has two churches, a court-house, and 1200 inhabitants. Keene, one of the prettiest towns in the state, has a church, court-house, gaol, and 1800 inhabitants.

In addition to the manufactories of Exeter, there are furnaces and iron works in Franconia; ninety looms in Hanover. The people generally make their own wearing apparel; and many articles for exportation. They also manufacture pot and pearl ashes, maple sugar, bricks and pottery.

The chief articles of export are timber of various kinds, dried and pickled fish, whale oil, tar, flaxseed, beef, corn, oxen and cows, horses, sheep, bricks, pot and pearl ashes. The importations are West India rum, gin, molasses, wine, porter, sugars, tea, coffee, cotton, cheese, nails, cordage, salt, sea-coal, steel, lead, and grindstones. The product of the fishery, in 1791, was 25,850 quintals. There have been ten banks incorporated in New Hampshire. Internal intercourse has been much facilitated by canals, locks, bridges, and turnpikes.

The shore of New Hampshire is chiefly a sandy beach interspersed by salt marshes, and intersected by creeks. Only two bluffs appear on the coast, the Great and Little Boor Heads; both in Hampton. Twenty or thirty miles from the sea, the country is either level, or made up of little hills and vallies. Above commences the first range of mountains; north and west of which are several detached ridges of considerable elevation. East of the Merrimac, and between that and Connecticut rivers, is the principal range of mountains in the state. The country on the whole may be denominated mountainous. The soil is generally fertile. The lands on the water courses are rich, and yield good crops of hay and wheat. The high lands produce on an average twenty bushels of wheat to the acre; and also afford good pasture. Pitch pine, white oak, chesnut, white pine, spruce, hemlock, birch, beech, maple, ash, elm, alder, red oak, and white birch, form the forest; and according to their ascendancy denote the soil hard, dry, sandy, thin, loamy, rich, deep, or moist. Winter rye thrives best on new, and maize or barley on old lands. Barley, flax, oats, and peas, will not succeed until the lands have been cultivated some years. Agriculture improves throughout the state. Orchards are multiplying and are productive. The rivers of Hew Hampshire are the Merrimac, Contoocook, Piscataqua, Ammonoosuc, Ameriscoggin, and Connecticut. It has several lakes; of which Winnipiseagee is the largest; being twenty four miles long, and from three to twelve miles wide.

In the township of Chester is an eminence 400 feet high, called Rattle-snake hill. It has a cave on the south side, called the Devil's Den, the entrance into which is near the base. In the town of Durham is a rock of 60 or 70 tons weight, so exactly poised, as to be easily moved by the hand. In the township of Atkinson, in a large meadow, there is an island of six or seven acres extent, which rises and falls with the water, when the meadow is overflowed.

The Isles of Shoals, 8 in number, lie 9 miles S. E. of Portsmouth light-house. They are barren rocks, inhabited by 100 souls, who subsist by fishing. *See Morse's Universal Geography, and The Constitution of the State, &c.*

---

HANAU is a town of Germany, and formerly capital of the county and principality of Hanau Munzenburg. This beautiful town is divided into the old and new town, the former of which was built in 1303, and the latter in 1597, by the Walloons. The town contains several churches, and the palace in which the reigning Landgrave of Hesse Cassel has apartments; but he generally occupies a small house at Wilhelmsbad when he comes to this part of the country. The garden of the palace, the pleasure house of Philippsruhe, and the baths of Wilhelmsbad in the neighbourhood of the town, are deserving of notice. Hanau contains manufactures of earthen ware, tobacco, woollen stockings, playing cards, arms, and articles in steel. Population 11,000.

---

HANCOCK, John, L. L. D. was born at Braintree, Massachusetts, about the year 1737. He was educated in the University of Harvard, and graduated Bachelor of Arts in 1754 On the death of his uncle, Thomas Hancock, esquire, he received a handsome fortune; and soon afterwards became an eminent merchant. He began his political career in 1766; when he was chosen one of the representatives of Boston to the assembly. His colleagues were James Otis, Thomas Cushing, and Samuel Adams, esquires. In the controversy between the colonies and Great Britain, Mr Hancock took the side of liberty and his native country, and rendered many distinguished and patriotic services. He was president of the provincial congress in 1774. On the 12th of June, 1775, general Gage issued a proclamation, offering pardon to all the rebels, excepting Samuel Adams and John Hancock, whose offences were alleged to have been too flagitious to admit of their exemption from condign punishment. At this period Mr Hancock was a member of the continental congress; of which he was chosen president on the 24th of May, in the place of Peyton Randolph, esquire, who was under the necessity of returning home. At the head of the illustrious congress of 1776, he signed the declaration of independence. In consequence of ill health, he took his leave of congress in October 1777; when he received the thanks of that body for his unremitted attention and steady impartiali-

---

HANDEL, George Frederic, a celebrated composer, was born at Halle in Saxony, in the year 1684. His father, an eminent physician, designed him for the study of the law; but the decided propensities which he displayed for music at an age when youthful genius rarely begins to expand, speedily demonstrated that his intentions would be disappointed. Handel is said to have privately resorted to a clavichord, an instrument strung with catgut, resembling a piano-forte, in a remote apartment, and continued playing upon it when the rest of the family had retired to sleep. His father, therefore, was induced to place him under the tuition of the organist of the cathedral; and at only nine years of age, he is said to have composed some motets which were adopted in the service of the churches. Distinguished musicians have sometimes exhibited similar precocious talents, but they seldom attain proportional excellence in maturer age: and if we admire the productions of children, it is generally in forgetting how much they would be undervalued were they the compositions of men.

The improvement of Handel, however, was great and rapid, and was strikingly displayed in the composition of an opera at the early period of fourteen, while he filled the ostensible situation of manager of the Hamburgh theatre. He was promoted to this situation in consequence of the flight of Keisser, the regular manager, who had attempted to assassinate him. Having composed the operas of Almeria, Florinda, and Nero, Handel proceeded to Florence, where he prudently resisted the consequences of an attachment, which an actress, who was mistress to the Grand Duke, had conceived for him; and repairing to other parts of Italy, he formed an acquaintance with Corelli and Scarlatti, famous musicians of that era. Then travelling to Hanover, he obtained a considerable pension from the Elector, afterwards Geo. I. of Britain, and arrived in London in 1710.

His fame had already preceded him, and he enjoyed high favour at court. Some of his compositions were intended for the practice of queen Anne; and when he returned to Hanover, after urgent solicitations by the admirers of music to remain in England, she dismissed him with a pension and valuable presents.

After a short interval, Handel revisited Britain, where he was more caressed than ever, and where his musical reputation began to extend. He first resided with the most distinguished persons, composing for performances, and managing some concerts for the nobility; and afterwards a society, called the Royal Academy, was instituted, by a subscription of 50,000*l*, to which the King contributed 1000*l*, for the execution of his works.

Handel now went to Dresden, in quest of performers for this great establishment, where he engaged a native of Siena, Francesco Bernardino Senesino, and Margarita Durastanti, two singers of celebrity, with whom he opened the Academy. But he had to contend with two formidable rivals in composition, Bononcini and Attilio, whose works were performed with applause in the Haymarket theatre. The friends of these three musicians, therefore, in order to decide their respective merits, agreed that

---

ty in the discharge of the duties of his office. He was succeeded by Henry Laurens, esquire, of South-Carolina.

On the adoption of the present constitution of Massachusetts, he was chosen the governor of the state, in 1780; and was annually re-elected until 1785, when he resigned. In 1787, he was again elected, and continued in the office of chief magistrate until his death, in October 1793. He died in the fifty-seventh year of his age. His administration of the government of Massachusetts was very popular. His deportment in office was manly and decisive. By his moderation and discretion, a civil convulsion, which broke out while he was at the helm of state, was completely quieted, without bloodshed. In his public speeches to the legislature, he acquitted himself with a popular eloquence seldom equalled. In one of his last official acts, he supported in a firm manner the sovereignty of the states. By a process commenced against the state of Massachusetts, he was summoned to answer the complaint of William Vassal in a court of the United States: but Mr Hancock declined the smallest concession, which might tend to establish a precedent unfavourable to the independence of the state, the interests of which were committed to his care; and in the controversy he supported his opinions with becoming dignity. Litigations of this sort were subsequently precluded, by an amendment of the constitution of the United States.

Mr Hancock was little devoted to science. He was more active than studious. He was of easy address, polished in manners, affable and liberal. As president of congress, he displayed admirable qualifications for the situation. He was sufficiently dignified, always impartial, quick in conception, and constantly attentive to business. He has rarely been rivalled in a similar station by any of his successors in the old congress; or in either house of congress, since the adoption of the constitution. General Washington, as president of the convention in 1787, is reported to have exhibited an almost inimitable pattern as a presiding officer. Aaron Burr, while vice-president of the United States, filled the chair and performed its duties with marked ability and distinguished elegance. Langdon Cheves, esquire, a representative of South-Carolina in the 13th congress, displayed a combination of qualifications to fill the chair in a deliberative body. He was very pointed in observing the rules of the house; most bland and flexible in his disposition and manners; but firm in maintaining his decisions and the dignity of the assembly over which he presided. He presided in the house of representatives at a very stormy time; yet in all the conflicts of party, and they were most violent, his decisions on points of order were uniformly supported; and it is believed that the nation is indebted to his nice discriminating sensibility, his firmness in duty, and peculiarly winning address, that the peace of the house of representatives was preserved, in the fearfully turbulent session of 1814—15, and the character of congress saved from the pollution of sanguinary discord.

From the commencement of the revolutionary war, he took an active stand against the encroachments of the mother country upon the rights of the colonists; and his uniform, energetic, and exemplary patriotism throughout the contest that ensued, is worthy of honourable remembrance. By his good conduct, in public and private life, he became a very popular man. A republican in principle, and a firm supporter of the cause of freedom, he had complete possession of the affections of his fellow citizens; and, whenever he became a candidate for the office of governor, he was uniformly elected by a decided majority. In private life he was charitable and generous. With a large fortune, he had the disposition to employ it usefully and benevolently. The poor shared liberally of his bounty. The university of Harvard experienced the benefits of his devotion to all institutions for the promotion of knowledge and happiness among the people of his beloved country. His donations to that institution were beneficent. Mr Hancock's oration on a memorable occasion, in Boston, has been preserved in most of our school books, as a pretty specimen of eloquence; and is often pronounced at public exhibitions in seminaries, where the students are taught the art of speaking. See *Allen's Biography*. (E. H. Cummins, A. M.)

each should compose the music for an act of an opera, called Muzio Scævola, of which the third fell to Handel's share. Public opinion unanimously declared in favour of the last; and it has been observed, that the performance of one of Handel's operas, after those of the other two, "is going from Arabia Petræa to Arabia Felix; from barren rocks to spontaneous fertility." Handel, therefore, held unrivalled possession of the stage. Some years afterwards, having profited by the talents of Francesca Cuzzoni, a female singer, of whom it was said, "that her intonations were so just and fixed, that it appeared as if she could not sing out of tune," he engaged Faustina, a young, beautiful, and interesting Venetian. But a rivalship commenced between them, and the audience participated in it so keenly, that, amidst the violence of partisans, the merits of the institution were altogether obscured. Each was supported with indiscreet and indecent zeal; and one of them having become refractory, Handel, from a previous example of the same in Senesino, refused to compose for this singer, and obtained his dismissal, probably in order to intimidate the others. By this, and some arrangements of a different kind, he offended the directors of the Academy, which led to its dissolution in nine years from its commencement.

Handel, however, endeavoured to carry on an opera at his own expence, while a rival amusement, patronised by many of the leading persons of the metropolis, was established in Lincoln's Inn Fields. But his success did not correspond with his expectations; and although he continued to compose, with great facility and expedition, his productions were at length performed to empty houses. Neither did his opponents experience better fortune; from which we may infer, that the English taste for operas was beginning to decline. Handel produced no less than thirty operas between 1721 and 1740; but in the latter part of this period, both his health and his fortune were so deeply impaired, that he left Britain to visit the baths of Aix-la-Chapelle.

Having returned to London in a state of convalescence, Handel began to direct his attention more particularly to another species of composition, oratorios, or sacred dramas, in which he expected, by the simplicity of songs, and the grandeur of chorus, to command that public notice which was denied to lighter compositions. The Messiah was performed at Covent Garden in 1741, and it will scarcely be believed, after an interval of 70 or 80 years, that it was but indifferently received. The inhabitants of Dublin, however, to whom the author had it performed for the benefit of the prisoners of that city, viewed it differently; and it was afterwards repeated in England to the most crowded audiences with unbounded applause. Many other oratorios followed in rapid succession, of which the majority were favourably received. The tide of public favour was restored to its original current, and Handel's merits gained their due appreciation. But some of his productions were nevertheless so little adapted to general taste, that the late King George II. attended them almost alone, when abandoned by the rest of his court. Handel annually superintended the performance of the Messiah, with laudable liberality, for the benefit of the Foundling Hospital, which produced above 500*l.* yearly.

In the year 1751, he was attacked by gutta serena; and from the moment that apprehensions for his sight were entertained, his spirits and vigorous imagination deserted him. An operation proving unsuccessful, his melancholy increased; and he was obliged to resort to extraneous assistance for the management of his oratorios. Years were now crowding upon him without bringing any alleviation of his disease; and when he, whose works had so often charmed an admiring audience, was led forward to make his obeisance; or when his own composition—"Total eclipse—no sun, no moon—all dark amid the blaze of noon,"—was performed, it is difficult to determine whether he himself or the spectators were most affected.

Handel was attacked by a general debility in 1758, and from that time he considered his own recovery as hopeless. Nor were his anticipations wrong, for he expired in April 1759, in the 76th year of his age. He was entombed in Westminster Abbey, and a statue was erected to his memory, as one, erected in Vauxhall Gardens in 1738, had already celebrated his genius. In person he was large, and rather corpulent and ungraceful; and in manners he was rough and impetuous. Over his performers he exercised a magisterial sway, exacting implicit obedience in the fulfilment of their respective duties; but it is probable, that posterity has heard his music to even greater advantage than was done by himself. He had no prominent vices, however, and he practised many virtues. Handel died possessed of considerable wealth for the period, and what must be esteemed great for a musician, whose fortune was once ruined; he left about 20,000*l.*, of which 1000*l.* was bequeathed to the Society for supporting decayed musicians, instituted in London in the year 1738. This Society derived 6000*l.* more, from the profits of a grand commemoration in honour of Handel, performed by 525 voices and instruments in Westminster Abbey in 1784.

Handel's merit as a composer ranks very high; and few if any have excelled him, in that particular path which he latterly chalked out for himself. The style of music indeed, has undergone inconceivable alterations since his death; but many of his compositions are even at this day heard with delight, though a century has elapsed since their production. His music is alike sublime in one character, and pathetic in another; and so long as simplicity and grandeur are valued by mankind, they will never lose their impression. The quantity that Handel wrote is surprising. It certainly exceeds what has flowed from the pen of any other composer, however voluminous his works; and it is so great, that we must be content with observing, that he produced between 40 and 50 operas, between 20 and 30 oratorios, besides organ concertos, and other music.

A complete edition of the whole, we believe, was published a few years ago, in 80 folio volumes. Although a large proportion of Handel's compositions are excellent, it is undeniable that many seem dull and heavy to modern taste; and the reiteration of favourite, or what he might conceive appropriate, passages certainly impairs their effect. The Grand Chorusses of the Messiah, the Coronation Anthem, Farewell ye limpid streams, Angels ever bright and fair, and numerous others, can never be listened to without emotion. Yet Handel, with all his excellence, committed that egregrious error to which musicians are so prone,—he wrote too much. It is vain to expect perpetual novelty in thoughts or actions; the inexhaustible renewal of human genius does not exist, or it appears only in arrangement. Nature has bestowed but a trifling portion of originality on any individual, however comprehensive his intellect; and so soon is that of composers bestowed on their works, that extravagance and caprice are offered for what is already exhausted. They enjoy a latitude, it is true, which is denied to literature or painting. These must be guided by certain principles which are special and defined, and of which the violation will ever be rejected by genuine taste. But music is not restricted within definite boundaries; while we acknowledge a few imperfections that should be avoided, we cannot describe that particular course which shall guide us to excellence. Hence public opinion will long be divided on musical merit; that which pleases the ear will gratify the majority; and the rest will seek for some less prominent property, which may be the subject of reflection. Perhaps a piece of music should be compared to a narrative, while it is agreeable in one part, nothing ought to be outdone in another. A general character should be preserved throughout. Were this attended to, fewer useless compositions, particularly instrumental compositions, would be obtruded on the public. Handel's works unquestionably evince the mind of a great master. He who can move an audience, both by pathos and grandeur, must be admitted to have no ordinary genius. Nevertheless he has perhaps fallen into another error, in endeavouring to make the imagination feel what it is necessary to behold, before being alive to the impression, or what it would probably require a kind of complex machinery to represent. For example, the sun standing still, a phenomenon of nature, from which we should at this day expect the annihilation of the terrestrial globe, is feebly imitated by a note of uncommon duration. The hopping of frogs, the buzzing of flies, the falling of hail, are sufficient in words; they are scarcely appropriate in music. Another inimitable master, Haydn, has followed the footsteps of his countryman in these questionable points. But how can any one discover flashes of lightning, the flowing of streams, the roaring of lions, or the crawling of worms, from any association of musical notes? Such allegories are beyond the reach of the most vigorous imagination, which would be perplexed in searching for the analogy. One of Handel's operas opens with an imitation of a storm and a shipwreck; and a symphony is introduced in another, to express the shrieks and cries of tortured souls in the infernal regions.

We must conclude on the whole, that Handel is one of the greatest masters who has ever flourished; and that his style and performance materially contributed to produce that revolution in music, which has taken place in the course of the eighteenth century. (*c*)

HANG-TCHEOU-FOO. See China.

HANNIBAL, the celebrated Carthaginian commander, was born about 220 years B. C.; and, when only nine years of age, accompanied his father Hamilcar to the army in Spain. Before his departure he vowed, at the altar, that he would never be in friendship with the Romans; and in the camp of Hamilcar, the most distinguished general of those times, he acquired that military skill, which afterwards rendered his enmity so formidable. At the death of his father, nine years after, he continued to serve in the field under his brother-in-law, Asdrubal, who had succeeded to the command; and when this general fell by assassination, about eight years afterwards, he was unanimously chosen by the army as their leader, while the senate at Carthage with one voice ratified the election. Soon after his confirmation in the command of the troops, he accomplished the reduction of the Olcades, and, loaded with booty, took up his winter quarters in new Carthage, (the modern Carthagena), where he completely secured the affections of the soldiery by his liberal distribution of the plunder, and the hopes of farther conquests, with which he inspired them. In the following year he reduced all the Spanish nations on the south of the Iberus, except the Saguntines, the allies of Rome; and, upon returning to his former winter quarters, received an admonition from the Romans to beware of molesting a people who had been taken under their protection. Conceiving the armies of his country to have now attained sufficient strength to contend with the legions of Rome, and eager to vent his long cherished hatred against that rival republic, he returned such an answer as clearly intimated his hostile intentions, and immediately transmitted to Carthage direct charges against the Saguntines, of having committed outrages upon the allies of the state. Having received permission to make reprisals, he pushed his measures with a celerity and decision which the Romans were not prepared to anticipate; and, after an obstinate siege of eight months, gained possession of Saguntum before any succours could be received from Rome. While the Romans were supposing the designs of the Carthaginians to have been limited to the reduction of Saguntum, and were preparing to send an army by sea to Spain, as the seat of the approaching contest, Hannibal, having secured the friendship of the Gauls on both sides of the Alps, began his march for Italy with an army of 50,000 infantry, and 9000 horse; evaded the Consul P. Scipio, who attempted, by landing at the mouth of the Rhone, to intercept his progress, carried his army across the Alps in the beginning of winter in the space of 15 days, and appeared in the vicinity of Turin, after a march of 1000 miles from New Carthage, accomplished in five months and a half. His army was now reduced to 20,000 foot, (of which 12,000 were Africans, and the rest Spaniards), and about 6000 cavalry. Having taken in three days the city of the Taurini, and put all who opposed him to the sword, he hastened forward to meet the Consul Publius Scipio, who had returned with the utmost expedition from the banks of the Rhone, and had already passed the river Po with his army. The two armies joined battle on the banks of the Ticinus, a small river in Lombardy; and Hannibal, chiefly by the superiority of his cavalry, gained an easy victory over a general, who was neither deficient in courage or experience, but who seems to have been little aware of the talents of his adversary. The other Consul, Sempronius, having arrived with a fresh army, acted with still greater rashness, and, engaging the Carthagioians near the river Trebia, sustained a much more decisive defeat. In the following campaign Hannibal was again fortunate in having to contend with a self-confident commander, Caius Flaminius; and, having carefully studied his temper, drew him into a defile by pretending a retreat, and cut to pieces, near the Lake Thrasymenus, the greater part of his army. But all his talents and expedients were brought into requisition by the dictator Fabius Maximus, who justly concluded, that to stop the progress of an invader is to gain a victory, and who cautiously directed his operations to preserve a commanding position, and to intercept the foragers of the enemy. The Carthaginian leader, baffled in all his artful movements to surprise his opponent, or to force an engagement, resolved at least to attach the neighbouring nations to his interests, by proving himself master of all the open country, boldly directed his march to the fruitful plains of Campania, which he quietly ravaged within sight of the Roman army. Upon attempting to return with his booty through the same pass by which he entered the country, he found himself, when encamped at the foot of Mount Callicula, hemmed in by the masterly movements of the Dictator; but by dispersing, during the night, 2000 oxen with burning faggots on their horns, he contrived to draw off the detachment which occupied the heights in the line of his march, and to bring off his army in complete safety. By taking care, in the general devastation, to spare the lands of Fabius, he encouraged the accusations and suspicions, which were ungenerously cast upon that general, of holding a secret correspondence with the enemy. In a short time he found means to draw into a snare the one half of the Roman army, commanded by Minucius, who had been raised to equal authority with the Dictator; but, when in full pursuit of the routed legions, he was checked by the advance of Fabius, and obliged to sound a retreat. While reluctantly retiring to his camp, he is reported to have said to his attendants, "Have I not often told you, that that cloud which hovered upon the mountains would one day burst upon us in a storm?" The Roman generals, enjoined by the senate to follow the plans of Fabius, continuing merely to watch the motions of the Carthaginians without risking a decisive engagement, he found his difficulties fearfully accumulating. Without any hope of succours from Carthage and left to the resources of his own genius for the means of subsisting his troops, in perpetual distrust of his allies in Italy, and daily assailed by the murmurs of his exhausted soldiers, he was on the point of sacrificing one part of his army to save the other, when the rashness of his adversaries again afforded him not only a season of respite, but an occasion of triumph. Having understood the fiery temper of Terentius Varro, one of the new consuls, (who held the command of the Roman army, and who bore, with the utmost impatience, the cautious counsels of Paulus Emilius, his colleague), he attacked him in all his detachments, insulted him even in his camp, and succeeded at length in drawing him into the field, near the fatal village of Cannæ. The Roman army consisted of 80,000 foot, and 6000 horse, and that of Hannibal amounted only to 50,000 in all, of which 10,000 were cavalry. Varro, on the day of his turn to command, impatient to punish, as he expressed it, the insolence of the Carthaginian, and confiding in the number of his troops, descended into level ground, as if he had studied to favour the enemy's superiority in cavalry; and in a battle which has already been described in the work, (see CANNÆ), lost nearly the whole of the largest army which had ever been equipped by Rome, while the loss of Hannibal did not exceed 6000 men. "Follow me," said one of the Carthaginian officers, elated with the annihilation of the Roman army; "I will be at Rome with the cavalry before they have notice of my approach. In five days we shall sup in the Capitol." To the refusal of Hannibal to adopt this advice, the preservation of Rome and its empire has been ascribed by Livy, and several other ancient historians; but many later writers have questioned the justice of the censure. Rome had been carefully fortified after the battle of Thrasymenus, and was provided with every thing necessary to sustain a siege. It was full of soldiers well trained to war, and supplied the dictator Junius Pera with four new legions and 100 horse, immediately after the battle of Cannæ. Hannibal's advantages had been principally gained by his superiority in cavalry, which could be of little use in attacking a city; and the rest of his army did not exceed 35,000 men. "His own judgment," says Dr Adam Fergusson, "is of more weight than that of the persons who censure him. He knew the character of the Romans, and his own strength. Though victorious, he was greatly weakened by his victories, and at a distance from the means of a reinforcement or supply. He was unprovided with engines of attack; and so far from being in a condition to venture on the seige of Rome, that he could not attack even Naples, which, after the battle of Cannæ, refused to open its gates."

Hannibal, soon after his victory at Cannæ, withdrew his army to Capua, the principal city of Campania, where he finally took up his winter quarters, sfter several unsuccessful attempts to gain possession of Nola, Casilinum, and particularly Naples, as affording an easy communication with Africa. Nothwithstanding the assertion of the Roman historians, that Capua, by its enervating pleasures, proved as fatal to the Carthaginians as Cannæ had been to the Romans, it does not appear that Hannibal or his troops had lost much of their martial activity and ardour. As soon as the rigour of the season began to relax, he renewed the siege of Casilinum in sight of an army from Rome, amounting, exclusive of allies, to 25,000 men; and the want of supplies from Carthage, which had indeed been promised, but were slow in their arrival, was the principal cause of his power declining in Italy. He had not troops to oppose the Roman armies, which were so rapidly collected against him, and at the same time, to garrison the towns and protect the countries which had submitted to his authothority or accepted his alliance. During the space of four years after the battle of Cannæ, no decisive advantage was gained by either party in the war; and though several victories are stated, by Livy and Plutarch, to have been gained over Hannibal by Marcellus, it is affirmed by Nepos, that the latter was always victorious in Italy, and by Polybius, that he was never vanquished before the battle of Zama. In the eighth year of the war, while Capua was hard pressed by the Romans, Hannibal made an attempt to draw off the besiegers, by marching to the gates of Rome, but found that city too well prepared to resist an attack which he seems after all to have rather feigned than intended. After the fall of Capua, he was frequently obliged to decline the battle which the Roman generals were now ready to offer; and at length, in the thirteenth year of the war, after the death and defeat of his brother Asdrubal, being unable to preserve his conquests in Italy, he retired with all his forces to the barren rocks of Brutium. Even in this weakened condition, in a country incapable of supplying him with subsistence, and at the head of an army composed of Africans, Spaniards, Gauls, Carthaginians, Italians, and Greeks, he continued, by his extraordiary talents as a general, to preserve the discipline of his troops, and to render himself formidable to the Roman commanders, till, in the 16th year of the war, he was recalled to Africa for the immediate protection of Carthage against the victorious legions of Scipio. Leaving Italy with the utmost reluctance, and landing at Little Leptis, a city between Susa and Adrumntum, he received instant orders from the Carthaginian Senate to advance and give battle to the Romans. In obedience to these instructions, he proceeded by forced marches to Zama, about five days journey south west from Carthage; and being struck with the undaunted generosity of Scipio in sending back the spies who had been taken in his camp, requested an interview with the Roman general. The armies had encamped within four miles of each other, and there was a large open plain between them, where no ambush could be laid. Here the two generals, escorted by an equal number of guards, arrived for the conference; and each attended by an interpreter, met in the midway, where they remained for a while in silence, viewing one another with mutual admiration. Hannibal first spoke and proposed a treaty of peace, upon terms which had been recently agreed upon between the two countries; but Scipio insisting upon the perfidy of the Carthaginians in breaking the truce during the negotiations, required them to surrender at discretion. Hannibal, however much disheartened by his misfortunes, and doubtful of victory, could not bring himself to make, at the head of an army, so humiliating a submission. The conference terminated; and both the generals returning to their camps, prepared for battle on the following day. According to the testimony of Polybius, Hannibal drew up his army in the most skilful manner, and performed every thing in the engagement which could have been expected from a great commander. The victory was long and eagerly contested; and the Romans, though superior in numbers, appear to have at one time been on the point of losing the battle. But Masinessa, who commanded the Numidian cavalry, and Lolius who headed that of the Romans, having routed the wings of the Carthaginian army, came in the rear of Hannibal's veteran soldiers, who were almost entirely cut to pieces in their ranks. Of the Carthaginians, 20,000 are said to have fallen in the field, and about the same number were taken prisoners. Hannibal escaped with a few horsemen to Adrumetum, whence he was called to Carthage, to aid the falling republic with his counsels. He instantly declared, that there was no resource except in a peace; and this reply from the constant advocate of the war, and most inveterate foe of the Roman name, decided the senate to submit to the conqueror. See CARTHAGE and ROME.

Hannibal, who had now spent thirty-six years in arms, continued to reside at Carthage; and was afterwards honoured with the chief magistracy in that republic. Having exerted himself to remedy various abuses in the management of public affairs, and having particularly brought to light many instances of the embezzlement of the revenue, he was accused by his enemies to the Romans of secretly holding intelligence with Antiochus the Great, in the designs which that prince was meditating against the power of Rome. In spite of the remonstrances of Scipio, (who generously defended his former opponent in arms, and strongly insisted that it was below the dignity of the Roman people to range themselves among the personal enemies of Hannibal, and take part in the factions of Carthage,) ambassadors were dispatched by the senate to bring the charge against Hannibal, and to require that he should be delivered into their hands. Aware of their design, and doubtful of his countrymen, he made his escape to Tyre, where he was received and entertained in a manner suited to his reputation; and afterwards joined Antiochus at Ephesus, whom he found in a state of hesitation between peace and war. Upon being consulted on the subject, he asserted, as he had always done, that the Romans were invincible every where but in Italy; proposed, if entrusted with 10,000 foot and 1000 horse, to make a descent in that country; and, at the same time, dispatched a messenger to Carthage to persuade them to join in the enterprize. Before the commencement of hostilities, a Roman ambassador, accompanied by Scipio Africanus, arrived at Ephesus; and, during their residence there, many civilities are said to have passed, and frequent conversations to have taken place between them and Hannibal. It is reported that, during this friendly intercourse, Scipio one day asked the Carthaginian, "Whom he thought the greatest general?" Hannibal immediately replied, "Alexander, because that, with a small body of men, he had defeated very numerous armies, and had overrun a great part of the world." "And who do you think deserves the next place?" continued the Roman. "Pyrrhus," replied the other: "he first taught the method of forming a camp to the best advantage. Nobody knew better how to choose, or post guards more properly." "And whom do you place next to those?" said Scipio. Hannibal named himself; at which Scipio asked, with a smile, "Where, then, would you have placed yourself, if you had conquered me?" "Above Alexander," replied the Carthaginian, "above Pyrrhus, and above all other generals;" thus, by a most refined strain of compliment, separating Scipio from the crowd of commanders, as one of inestimable qualities. These familiar conversations are said to have been sought by the Roman deputies, for the purpose of discovering the designs of Hannibal; and they had at least the effect of rendering him suspected by Antiochus. That prince, though afterwards cured of their suspicions of his guest, refused to follow his counsels as to the prosecution of the war; and, upon suing for peace after his defeat at Magnesia, was required, among other conditions, to deliver up Hannibal to the Romans. This illustrious exile, however, anticipating such a demand, had removed from the dominions of the Syrian monarch, and taken refuge with Prusias, king of Bithynia, to whom he rendered eminent services in various wars. At length Flaminius arrived as an ambassador from Rome, for the ostensible purpose of requiring Prusias to desist from hostilities against the king of Pergamus; but principally with a view to induce him to betray his Carthaginian guest. The king, reluctantly, according to Plutarch, but readily, according to Livy, complied with the dishonourable proposal; but Hannibal, who resided in the castle of Libyssa, upon learning that the place was surrounded by soldiers, resolved to die, rather than fall into the power of his persecutors. Taking into his hand a poison which he had kept ready for such an exigence, "let us deliver Rome," he said, "from her perpetual fears and disgust, since she has not patience to wait for the death of an old man." Then, having invoked the gods to take vengeance upon Prusias for his violation of hospitality, he swallowed the poison and expired. He died at the age of 65 years, of which he had passed 36 in camps, and 13 in exile. He had little opportunity, therefore, to cultivate the moral and civil virtues; though, perhaps, if impartially tried even by this test, he will be found, notwithstanding the shocking portrait drawn of him by Livy, to have been by no means inferior to the great body of conquerors in ancient times, or even to his celebrated opponent Scipio Africanus. Neither Plutarch nor Polybius makes any mention of that cruelty, perfidiousness and irreligion, with which he has been charged. In point of military talents, he may be pronounced to stand in the foremost rank; and all the qualities which make a complete general, have not been more constantly and conspicuously manifested in the conduct of any captain of antiquity, than in that of Hannibal. He appears, especially, to have surpassed them all in the talent of forming brave and disciplined soldiers; though he was opposed by troops, consisting chiefly of Roman legions, warriors by choice and education, he was victorious, even over superior numbers, in every battle except his last; and that with an army, which he had in a great measure renewed in conquered countries, which he had collected from various nations, differing in manners and language, and which he preserved attached to his interests in the midst of privations and reverses. See Nepos, Livy, Plutarch, Polybius; Rollin's *Ancient History*, vol. vii.; Ferguson's *History of the Roman Republic*, vol. iii.; Abbé de St Pierre's *Life of Scipio Africanus*; and Hooke's *Rom. Hist.* vol. iv. and v. (*q*)

# HANOVER.

Hanover is a kingdom of Europe, which was formed in 1815 out of the electorate of Hanover and the principality of Osnaburg. It is situated in the circle of Lower Saxony; and is bounded on the north by the territory of Hamburgh, Holstein, and Mecklenburgh, the Elbe forming the line of demarcation as far as Inapesse; on the north-east by Prussia; on the east by the duchies of Brunswick and Prussia; on the south by Hesse and Prussia; on the west by the lands of Lippe, Hesse, Waldeck, and Prussia; on the north-west by the territory of Bremen, and the possessions of the Duke of Olders, and the territories of Aremberg and Looz.

Hanover is of a very irregular form. It comprehends the duchies of Luneburg-Zell, Bremen, Verden, and Saxe Lauenburgh, on the northern side of the Elbe; the countries of Calenburg and Grubenhagen on the south; those of Diepholtz and Hoya on the west; and that of Danneberg on the east. At the treaty of Ratisbon, Hanover lost the bailiwick of Wildehausen; but in 1802, it acquired the principality of Osnaburg.

1. The principality or duchy of Luneburg-Zell, is bounded on the north by the duchies of Lauenburg and Mecklenburgh; on the east by the electorate of Brandenburg and duchy of Brunswick; on the south by those of Brunswick and Calenburg; and on the west by the circle of Westphalia. The Elbe forms the north and north-east boundary. It is from 75 to 80 miles from north to south, and from 60 to 70 from east to west. It contains 200 parishes and 27 towns. It possesses some fruitful marsh lands along the Elbe, the Aller, and the Jetze; but towards the centre and northern parts, it is sandy, heathy, and barren. The principal towns are Luneburg, Harburg, Zell, Helzen, Danneberg, and Lucho.

2. The duchy of Bremen, is bounded by Holstein, Luneburg, Verden, and Westphalia. It is about 65 to 70 miles long from north to south, and 45 to 50 from east to west. The Marschland, or low country, on the rivers Oster, Weser, and Elbe, is fertile, but liable to inundations. The Geestland, or high country, is in some places fruitful, and has its heaths covered with sheep. In this duchy are 2 cities, 12 market towns, 22,276 taxable hearths, 118 Lutheran churches, and 28 noble jurisdictions. The principal towns are Bremen, Stade, Buxtehude, Closter Seven or Zeven.

3. The duchy of Verden, which has a peninsular form, lies on the right bank of the Weser, between Bremen and Luneburg. The extent from north to south and from east to west, is from 25 to 30 miles. It is an elevated, heathy, and dry country, traversed by the rivers Aller and Wummie. Its principal towns are Verden, Rottenburg, and Languedal.

4. The duchy of Saxe-Lauenburg, is bounded by Holstein, Mecklenburgh, and Luneburg, and the territories of Lubeck and Hamburgh. The country is level, and in some places fertile. It yields considerable quantities of wood and flax, and exports rye, butter, cheese, wool, wood, and fish. The small rivers Belle, Steckenitz, &c. which fall into the Elbe, water the southern part of the duchy. The principal lakes are those of Ratzeburg and Schall; and the chief towns Ratzeburg, Lauenburg, and Mollen.

5. The principality of Calenburg is situated in the south-west corner of Lower Saxony, and is cut into two parts by a part of the principality of Wolfenbuttel. The northern part is bounded by Luneburg, Hildesheim, Pyrmont, Lippe, Schauenburg, Hoya, and Minden; and the southern part by Wolfenbuttel, Grubenhagen, Eichfeld, and Lower Hesse. It is about 48 leagues long, and from 6 to 10 broad. The Weser, which forms part of the western boundary, is every where navigable. The country is in some places hilly, and in others marshy and sandy, and no where very fertile. The principal hills, are the Deister, Suntel, and Solingerwald. The principality contains 36 towns, and 221 churches. It is divided into three quarters, viz. 1. The quarter of Hanover, which contains 11 towns, 2 abbies, 6 convents, 81 manors, and 212 villages. The chief towns are Hanover, Munder, Wunstorf, Pattensen, Eldagsen, &c. 2. The quarter of Hameln and Lauenau, which contains 13 towns, and 128 villages. The principal towns are Hameln, and Bodenwarden. 3. The Gottingen quarter, which contains 15 royal bailiwicks, 11 noble jurisdictions, 12 towns, 8 convents, and 180 villages. The chief towns are Gottingen, Nordheim, Munden, Dransfeld, Moringen, Uslar, and Hardegsen.

6. The principality of Grubenhagen, is bounded by Calenberg, Wolfenbuttel, Wernigerode, Blankenburg, Hohenstein, and Eichfeld. The greater part of this principality is mountainous, and covered with woods. It contains, however, some fruitful plains, where considerable quantities of flax are raised. Grubenhagen contains a part of the famous chain of the Hartz. The principal minerals which it contains, are slates, alabaster, marble, rock salt, calamine, sulphur, lead, copper, iron, silver, and gold. For an account of the produce of the mines, see p. 243. Grubenhagen contains 9 small towns, 44 parochial churches, and 7000 taxable hearths. The chief towns are Einbeck and Osterode, which are described in p. 245.

7. The county of Diepholtz is bounded on the north by Delmenhorst and Bremen, on the east by Hoya, on the south by Minden, and on the west by Osnaburg and Munster. It is 25 miles long from north to south, and 10 to 14 from east to west. This county consists of heaths, moors, and pasture lands; and the people are chiefly employed in breeding cattle, and manufacturing coarse linens. It contains ten parishes, and five towns, the principal of which are Diepholtz and Lemforde.

8. The county of Hoya is bounded on the north by Delmenhorst, Bremen, and Verden, on the east by Luneburg and Calenburg, on the south by Minden, and on the west by Minden and Diepholtz. It is 25 to 30 miles from north to south, and 30 to 33 from west to east. The soil is chiefly sandy; but there are some fruitful tracts, which produce wheat, barley, and flax. Some parts are heathy, and others fit for pasture. It contains 54 parishes, and 100 towns and villages, the chief of which are Hoya, Drakenburg, Nienburg, Liebenau, Suhlingen, Harpsteadt, &c.

9. The principality of Osnaburg is bounded on the north and south by Munster, on the east by Hoya, Minden, and Ravensberg, on the west by Techlenburg and Lingen. It is about 43 miles long from north to south, and 32 from west to east. The river Hase traverses it from north to south. Nearly one half of the county consists of heathy and barren land. Rye and flax are its chief produce. It

contains seven towns, the principal of which are Osnaburg, Iburg, Furstenau, Quackenbruck, Vorden, and Wiedenbruck. See OSNABURG.

Hanover comprehends 107 bailiwicks. The country is intersected by a great number of rivers and streamlets, and is in general extremely marshy. The principal rivers are the Elbe towards the north, the Weser and the Leine on the west, and the Aller and the Ilmenau in the centre of the kingdom. The chief lakes are those of Diepholtz and Stinhuder. The Aller rises in the duchy of Magdeburg; and, after traversing the southern parts of Luneburg-Zell, it falls into the Weser below Verden. The Leine rises in Eichfeld, runs northward through the eastern part of Calenburg, and falls into the Aller. The lake of Diepholtz is called the Drummer-see, and though very extensive is extremely shallow.

The climate is by no means good. The temperature is very variable. The winters are rigorous, and frosty days often intervene between the greatest heats of summer. A north-west wind commonly blows during the cold season, an east wind in spring, and a south-west wind in summer. The common diseases are catarrhs, intermittent and nervous fevers, phthisis, apoplexy, and palsy. When July is very warm, dysenteries are peculiarly malignant. The epidemics are of a rheumatic nature, and consumptions are very fatal.

The Hartz mountains are the most considerable in the kingdom. See HARTZ. The mountains which separate the west and south of Hanover from the principality of Hesse are either of a calcareous or basaltic nature, and consist of large pyramidal blocks, which furnish excellent stones for mending the roads, and paving the streets.

Very little progress has been made in improving the heaths and the marshy grounds of Hanover. A few fertile spots are occasionally seen in the midst of barren wastes, although, by a little judicious management, a great part of the soil might be brought under cultivation. Nearly one half of the land is covered with weeds; a fifth part of the arable fields is employed in pasturage; and of the parts from which grain is raised, a third is occupied by peas and beans, a fourth by wheat, rye, and buckwheat, a fifth by barley, and a sixth by oats. On the sandy lands good potatoes are produced. Notwithstanding the general sterility of the country, there are many fertile and populous vallies on the banks of the Elbe and the Weser. The duchy of Saxe Lauenberg is completely cultivated, owing to a wise agreement between the seigneurs and the peasants to relinquish some mutual privileges. The grain raised in Hanover is not sufficient for the consumption of the inhabitants; but though the pasturage is not luxuriant, they export a considerable number of horses to France, Italy and Saxony. If the operation of draining were extensively carried on, Hanover might supply Germany, Holland, and France, with a sufficient number of horses and black cattle. The wool is of a very bad quality. It is used in Belgium in the manufacture of coarse cloth, and the Hanoverians work it into a tolerably good looking stuff. Several rams of the Merino breed have, however, been imported from Upper Saxony; and the wool has thus been greatly ameliorated. The cows are neither large nor beautiful. They are generally of a black and white, or a white and fawn colour. In order to improve the breed, bulls are brought from Holland. The Hanoverian goats are very poor, and few in number. The oxen are of a middle size, and make excellent beef, the pork is good, and the mountain mutton is highly esteemed. Flax is more abundant than hemp throughout the kingdom, and it is the chief occupation of the females to spin it in the winter evenings.

The natural history of this country is in no respects interesting. Boars and deers are much less numerous than formerly; and, during the last century, wolves have been extremely rare. The last bear was killed at Hartz about the beginning of the 18th century. Roebucks and hares are excellent, but rabbits are very scarce. Thrushes, partridges, skylarks, wild-ducks, heathcocks, and a small species of tetran, are very numerous. The rivers do not produce a great variety of fish, but the markets are well supplied with turbot, perch, carp, pike, and large eels. The streams that issue from the Hartz, and other wooded mountains, abound with a small trout of exquisite flavour. The mineral waters of Limmer are much frequented. The hot baths of Limmer are built of grey stone, firmly cemented, and fixed in the ground. The descent is by four steps, with a ballustrade. A bench 5 inches broad serves for a seat, and it has a fir back, in order to prevent a sudden shock from the cold stone before it has acquired the temperature of the water. The charge for each bath is a franc.

The minerals of this country are rich and numerous: They consist of silver, copper, lead, iron, cobalt and zinc, with marble slate, coal, turf, and limestone. Boracite has been found in the Calkberg and Staurolite at Andreasberg in the Hartz. The annual produce of the mines of the Hartz which belong to Hanover, is reckoned at 1,172,733 rixdollars. The annual produce of the lead mine called Caroline is 194,000 rixdollars. See the article HARTZ.

The territory of Hanover is governed by a regency, composed of seven ministers. Four of these reside in Hanover, the capital; and the fourth, who presides over the law department, the police, and the high court of appeal, resides at Zell. The sixth, who is at the head of the College of Nobles, likewise presides over the subordinate regency of Bremen and Verden, which is held at Stade; and the seventh has a permanent establishment in the court of the electoral king. This regency possesses regal power, and decides in all matters on which the provincial states are not entitled to interfere. It communicates with these assemblies in the same manner as the elector himself, and superintends all the departments of the government. There is a subordinate regency for the bailiwicks of Lauenburgh, which sits at Ratzeburg, and another for the principality of Osnaburg, which sits at Osnaburg.

The provincial states of the kingdom consist of the prelates of the equestrian order, and the magistrates of cities. The priests are of the first rank, the nobles are of the second, and the magistrates of the third rank. The duty of the states is, to watch over the liberties of the people and the different orders of the citizens,—to enforce a regular administration of the laws,—and to superintend the distribution of the public money. No tax can be levied without their consent, and every new law must have their sanction.

The Roman and public law, the constitution of the empire, the bulls of the emperors, and the particular constitutions of the different provinces of which Hanover is composed are precedents, by which the magistrates are guided in their political, civil, and criminal judgments. The high court of appeal sits at Zell, and the minister is bound to consult the regency in certain difficult cases. The decisions of this court have always been highly respected. When M. Wrisberg was its president, George II. one day said to him, "How does it happen that I lose every process that I bring before your tribunal?" "Sire," replied the president, "it is because your Majesty is always in the wrong." "M. de Wrisberg," replied the king, "you speak to me like a magistrate." Capital punishments are very rare in Hanover. The principal punishments are fine, reprimand, detention in a house of correction, imprisonment, or compulsion to labour for a limited period. Breaking on the wheel is still practised in this country, but it is always preceded by strangulation. Every sentence, however, which inflicts this punishment, must be submitted to the deliberation of the regency. Public works, where the criminals labour, are established in five of the principal cities: the more hardened are sent to Hameln, and others to the quarries of Luneburg. The use of preparatory torture is said to remain unabolished.

The revenues of the kingdom are derived principally from a tax on land,—from a contribution from the peasantry in money, grain, and labour on the roads,—from a poll tax from the different classes of citizens,—from duties on cattle, on the consumption of luxuries, and on salt, coals, and turf. Taxes are also levied on mills, leases, horses, and public carriages, and considerable sums are obtained from tythes,—from tolls on the transit of goods,—from the custom-house, the forests, fisheries, game-laws, the mines of Hartz, the coinage of money, and the postage of letters. The total amount of the revenues has been estimated at 962,500*l* sterling. The national debt is considerable, and was principally contracted to support the seven years war.

Hanover has 10 garrison towns, viz. Hanover, Munden, Zell, Luneburg, Nienburg, Stade, Harburg, Ratzeburg, and Osnaburg. The works of Hameln and Harburg are the most considerable. The fortifications of Stade were demolished in 1781, but those erected on the Klutberg, above the Weser, in 1760, and called Fort George, have become very strong from the addition of new works, The military commandants of these garrison towns enjoy no rank in the army. The following is the military force:—

| | |
|---|---|
| Infantry | 12.015 |
| Cavalry | 4,600 |
| Artillery | 671 |
| Corps of engineers | 95 |
| Militia | 5,500 |
| | 22 881 |

The soldiers are all Hanoverians. The cavalry is generally composed of the sons of farmers, and the militia consists of pensioners who have served 25 years in the army. They have the same organization, equipment, and clothing as the regular troops. The operations of the commander in chief are subordinate to the regency. Every soldier has a right to demand his discharge after 20 years service, and he is entitled to a pension according to his rank. The number of invalids amounts to 7000. No British subjects are employed in the Hanoverian army. The cannon foundry is at Hanover. It is situated on the glacis of the city, on the side next the road leading to Zell. The only manufactory of small arms is one at Hertzberg, which enjoys much reputation in Germany. The best gunpowder is made at Hersen near Hameln. The manufacture of cannon and of powder are both carried on by private individuals.

Hanover contains about 750 parishes, with seven superintendants. The people are divided into Jews and Christians, and the Christians into Catholics, Calvinists, and Lutherans. Before the union of Osnaburg, the Jews were the most numerous sect next to the Lutherans. The Jews are the principal bankers in the large cities, and they keep butchers' shops in the small villages.

The Lutheran is the established religion. The supreme consistory, composed of some of the most enlightened citizens, has the right of superintending all the other sects. The Lutheran clergy are supported by a portion of the property which once belonged to the Catholic church; but the greatest part of it is appropriated for the university of Gottingen, the lyceum of Hefeld, and other public institutions. The ministers of the other sects receive a small sum from government, and derive the rest of their income from their parishioners. The Calvinists are few in number, and there are only a very few Roman Catholics in the kingdom.

A regular system of instruction was adopted in Hanover after the year 1750, in consequence of the liberality of M. Botticher, who endowed a seminary for schoolmasters in the city of Hanover. The electorial regency did all in its power to promote the objects of this institution; and, in order to combine practical with moral and literary knowledge, the children of both sexes were taught to sew, spin, knit, &c. In the middle or secondary schools are taught geography, history, drawing, the French and English languages, together with the elements of geometry. In the academies, or schools of the third order, are taught antiquities, and the Latin, Greek, and other languages. Academies of this kind are established at Zell, Clausthal, Einbeck, Hameln, Hanover, Harburg, Ultzen, Hefeld, Gottingen, Bremen, Luneburg, Minden, Nordheim, Osterode, Stade, and Verden. Besides these academies, there are establishments at Hanover and Luneburg for the education of the young nobility of both sexes, from the period of eight to fifteen years of age. The Georgianum, an establishment of this kind, was founded in May 1796 for the education of 40 pupils, who must be the sons of Hanoverian nobles. Every pupil pays at his entrance about 95 thalers, or nearly 16*l*. sterling; and 15 of those whose parents can afford it pay the additional sum of 120 thalers. They are all boarded, clothed, and taught, at the expence of the establishment. Their dress is a blue uniform, faced with scarlet. They are admitted at the age of 10, and as soon as they have received a suitable education, they may either enter into the military service, or pursue their studies at the University of Gottingen, in order to fit themselves for any other profession. Those who enter into any regiment receive 260 thalers for their equipment out of the funds of the institution; and the most distinguished of the pupils, who are sent to Gottingen, enjoy an annual income of 300 thalers during their three years residence at the university. Belonging to the institution is an excellent library, a collection of natural and artificial curiosities, and a good philosophical apparatus. Primary schools are established in every village; while schools for the classics and the elements of the sciences are founded in all the principal towns. The university of Gottingen is provided with 42 professors. See Gottingen.

Hanover is very far from being a commercial country. At the four fairs which are held annually at Hanover, and the two at Osnaburg, are exposed to sale the commodities which have been purchased at the fairs of Brunswick, Leipsic, and Frankfort. They consist chiefly of earthenware, agriculture and handicraft implements, pins, needles, coarse linen drapery, baskets, coarse stuffs, lace, thread, ribbons, and toys. Articles of English merchandise are brought from Hamburgh, Emden, Bremen, and Brunswick; and the linens of Friesland and of Prussia, and the cloths, silks, and jewels of France, are also met with in Hanover.

A great deal of plain and table linen is manufactured in Hanover. At Osnaburg the most common employment is spinning flax, which is afterwards wrought up into damask, greatly inferior to that of Prussia and Friesland. The greater part of it is sold at home; but in times of peace, the surplus is exported, through the Hanse towns, to North America and the Spanish colonies. Very little hemp is raised in Hanover. Their domestic linens are principally made of flax, which is never spun sufficiently fine to be made into lawns or cambrics. There are also manufactories for coarse cloth and paper, several tanneries, and some glass-houses; and a manufactory for iron and copper utensils at Hartz. The coarse cloths are principally used by the poor, and for clothing the army. The paper is inferior to the Dutch and French papers. One half of the leather, which is not good, is consumed in the kingdom, and the other half exported to Saxony and Belgium. The best glass is made in the bailiwick of Lauinstein. The manufacture of iron articles at Hartz is said by Mangourit to be superior to any thing of the kind carried on in France. Silver plate, jewellery, gold and silver lace, embroidery, and saddlery, are made at Hanover. Diamonds are set in a very superior manner, and the artists also cut white, yellow, or red amber globes, with facets for ear-rings, necklaces, and bracelets, which are bought by the Jews, and sold at an enormous profit.

The principal articles of export are, horses, black cattle, wax, lead, linens, leather, salt, oats, barley, thread, the iron and copper of Hartz, the turf of Bremen, and planks of timber. The two last articles are bought by the merchants of the Hanse and maritime cities.

The principal towns in the kingdom of Hanover are, Hanover, Gottingen, Bremen, Osnaburg, Stade, Ratzeburg, Munden, Zell, Hameln, Klausthal, Einbeck, Harburg, Ultzen, Lauenburg, Mollen, Hefeld, Nordheim, Osterode, Verden, and Nienburg.

Einbeck, or Einbike, the capital of the principality of Grubenhagen, is a walled and fortified town, situated in a fertile territory at the confluence of the Ilm, Krumewasser, and Leine, near the borders of Calenburg. Besides ramparts, bulwarks, and towers, it has moats and outworks. Considerable quantities of woollen cloth are made here, and it has several breweries. Its population is 4500. Osterode, containing 4000 inhabitants, is situated six leagues east of Einbeck, at the conflux of the Sole and Apenke. It has an ancient castle; and a manufacture of camblets, besides quarries and mills, and lime-kilns. Nordheim, erected into a town in 1252, is situated on the Ruhme, which here divides itself into two branches, a few miles above their influx into the Leine. The organ of the parish church is famous for its immense size. Tobacco is cultivated in the neighbourhood, and it has several flourishing manufactures. Near this town a sulphureous spring was discovered in 1804, and baths have been erected at the house of the woodkeeper. It contains 3000 inhabitants. Ultzen, or Uelzen, is a trading town, consisting of 330 houses, situated on the Ilmenau, at the confluence of several small streams. It had formerly a great trade in flax, linens, wool, wax, and butter; but it is now on the decline. Verden has a fine cathedral, with very interesting monuments, and a population of 4000. Danneberg is a decayed town of 160 houses, with a ruinous castle on an eminence, watered by the Tetze. The chief export is beer. Nienburg is situated on the Saale, in upper Saxony, but near the borders of Lower Saxony, it has a fine stone bridge over the Weser. It contains a palace erected out of a convent of monks, and is celebrated for a kind of beer like English ale. For an account of the other towns, see Bremen, Gottingen. Hameln, Hanover, Harbourg, Klausthal, Luneburg, Munden, Osnaburg, Ratzeburg, Stade, Zell.

The illustrious house of Hanover is descended from Margrave Azo, who possessed the Milanese, Genoa, and part of Lombardy, in the 11th century. He was succeeded by Welpho the Fat, who married the Marchioness of Tuscany. Welpho having died without issue, his Italian estates, and the duchy of Bavaria, came into the possession of his brother Henry the Black, who obtained the county of Luneburgh with his wife Wulphilda, daughter of Magnus Duke of Saxony. His son Henry the Proud having married the daughter of Lotharius II. obtained along with her the duchy of Saxony, and the hereditary lands of Brunswick Nordheim, and Supplingenburg; and the dominions of the family extended from the Rhine to the Vistula, when her son Henry the Lion reduced the Slavi, on the coast of the Baltic. In 1179, he was put under the ban by the Emperor, and deprived of all his possessions in Italy and Swabia, and of the duchies of Saxony and Bavaria. He was allowed, however, to retain Luneburg, some lordships, and his Slavian conquests. His son Otho obtained the imperial dignity in 1209; and, in the course of time, his family was divided into two branches, two of which now exist, viz. those of Wolfenbuttel and Zell. The first was founded by Henry, and the second by William, the sons of the Duke Ernest, who introduced into his dominions the reformed faith. Ernest Augustus, his grand nephew, and Elector of Hanover, married Sophia, the daughter of the Elector palatine, and of Elizabeth, the daughter of James I. of England, and established the right of primogeniture in the Wilhelmine line. In the year 1714, George Louis his son succeeded, in virtue of the act of succession, (see Britain,) to the throne of England, and since that time the kings of England have been the electors of Hanover. In the year 1715, the Duchy of Verden was ceded to the Elector of Hanover by the alliance concluded at Wismar; and in 1719, by the treaty of Stockholm, Bremen was also transferred to the elector, who, in 1732, obtained the emperor's investiture for both Bremen and Verden. In October 1801, the Prussians, under the fatal influence of the government of France, had declared war against Great Britain, and had taken possession of the Electorate of Hanover; but at the peace of Amiens, the electorate was restored to its lawful sovereign. The Bishopric of Osnaburg, or Osnabruck, which, by the peace of Osnaburg, was to be occupied alternately by a Roman Catholic and a Lutheran bishop, the last of whom must be selected out of the house of Brunswick Luneburg, was secularised by the treaty of Luneville, and was ceded by the treaty of Amiens, in 1802, to George III. as elector of Hanover.

When Bonaparte had determined to make war upon Great Britain, he marched his army into Osnaburg and Hanover. On the 9th of June 1803, the French, under the command of General Drouet, took possession of the country and city of Osnaburg; and after a slight engagement, the convention of Suhlingen was entered into on the 3d of June 1803, between General Mortier and Marshal Walmoden, the commander of the Hanoverian army. The first consul immediately sent this convention to England, declaring that he would ratify it as soon as it had been sanctioned by his Britannic Majesty. The English government, however, refused to give any sanction to this convention. They averred, that the character of George III. as elector of Hanover, was distinct from his character as king of Great Britain, and that in the year 1795, the French government had acknowledged his neutrality as elector of Hanover during the existence of a war with Great Britain. The king therefore resolved to abstain from every act which might be considered as contravening the stipulations of the convention concluded on the 3d of June, between the deputies appointed by the regency of Hanover and the French government, until he should make an appeal to the empire and to the powers of Europe, who had guaranteed the Germanic constitution, and consequently his rights and possessions as a prince of the empire. On the 30th of June, General Mortier communicated the resolution of the British government to Marshal Walmoden, and summoned him to surrender his army in 24 hours, to be sent prisoners of war into France. The Hanoverian general declared that his army should perish in the field rather than consent to such humiliating terms. General Mortier was thus induced to offer milder terms, and a capitulation was signed on the 4th of July, by which the Hanoverian army laid down its arms, which, with all the artillery, was to be delivered up to the French, along with the cavalry and artillery horses, to the amount of 4000. The soldiers were to return to their respective homes, and engaged not to serve against the French till regularly exchanged.

Hanover continued in the possession of the French till the year 1806, when it was occupied by the Prussians. It was afterwards annexed to the new kingdom of Westphalia, which was formed for Jerome Bonaparte.

In consequence of the great events in 1813, (see France,) which have led to the liberation of Germany, Hanover was restored to its ancient rights, by the army of the Crown Prince of Sweden. It of course reverted to its legitimate sovereign at the treaty of Paris in 1814, and has since continued in a state of tranquillity and happiness. At the second treaty of Paris, in 1815, the electorate of Hanover was converted into a kingdom.

The population of Hanover is about 800 000 souls, which gives about 1500 to every square German mile. The population of the principality of Osnaburg is about 133,000; so that we have, according to Mangourit,

| | |
|---|---|
| Hanover Proper . . . . . . . . . | 800,000 |
| Principality of Osnaburg . . . . | 133,000 |
| Population of Osnaburg . . | 933,000 |

The following is another estimate of the population:

| | |
|---|---|
| Principality of Calenburg, . . . . | 210,000 |
| Principality of Luneburg-Zell, . . . | 200,000 |
| Duchy of Bremen, . . . . . . . . | 167,149 |
| Principality of Osnaburg, . . . . | 117,896 |
| Principality of Grubenhagen, . . . | 80 000 |
| Duchy of Saxe Lauenburg, . . . . | 40,000 |
| County of Hoya . . . . . . . . . | 40,000 |
| Duchy of Verden, . . . . . . . . | 30,000 |
| County of Diepholtz, . . . . . . . | 12,000 |
| | 897,045 |

See particularly Mangourit's *Travels in Hanover*, during the time of its occupation by the French; Catteau de Calleville's *Voyage en Allemagne;* Peuchet's *Dictionnaire de la Geogr. Commerc.*; and the article Hartz.

HANOVER is a fortified town of Germany, and capital of the kingdom of the same name. It is situated in a sandy plain, on both sides of the river Leine, which divides it into two towns, viz. Old and New Hanover. The old town lies on the left bank of the river, which here forms two branches, and, after inclosing an island, they again reunite and become navigable. The old and new towns are connected by bridges. The town is built in the form of a half moon, and contains several good streets. The houses of the new street called George-strass are all built on the same plan. This street, or rather row, is built along the side of a fine rampart, from which it is separated by iron chains, resting on pillars of free-stone. There is a Gothic appearance in most of the buildings of Hanover. The houses resemble the galleries of a vessel of the sixteenth century, and the time of their erection is always marked upon them. In those dated 1565, each story projects several feet over the one below it, and exhibits medallions, pagan deities, warriors, and verses of the Psalms. Red and green bricks are intermixed in some of the edifices, and in others varnished tiles are arranged in rows. Sometimes bricks are only used for the doors and windows, while the rest of the house consists of wood, painted of various colours. In some houses, the bricks are placed in wooden frames, and secured by plaster. The town, however, contains many handsome buildings. The Elector's palace, which, after being destroyed by fire, was rebuilt in 1791, is a fine building, constructed of hewn stone. This was the seat of the regency. The newly erected part of the electoral church, and the palace of the Princess of Wales, are likewise excellent buildings of stone. Hanover contains also a theatre, three parish churches, a poor-house, and three hospitals. The public library of Hanover is a respectable building. The first story is appropriated to charts, state papers, and judicial records. The upper stories contain works of imagination and belles lettres. When the French threatened to invade Hanover, the Elector ordered the four copies of the beautiful Oxford Bible, the books, and the precious monuments, to be packed up and removed. We believe that they were afterwards sent back to the capital. This library was founded by Leibnitz, who bequeathed to it his own fine collection of books. There are two portraits of this great man in the library, one at the age of 40, and the other at 60; and the arm-chair in which he expired is there carefully preserved. His remains are interred under a stone in the Lutheran church in the new city. A very fine monument is also erected to his memory by private subscription. It is an Arian temple, situated in an umbrageous thicket, at the end of a long avenue of linden trees. Twelve columns of the Tuscan order, of hard grey stone, quarried in the Hartz mountains, support a light cupola, beneath which is placed a white marble bust of Leibnitz, taken from the picture of him at the age of 60. "To the memory of Leibnitz," is the simple inscription which reminds us of the labours of this great philosopher.

The cemetery of the Jews is situated on an oval eminence near the city; and that of the Lutherans is a vast field, surrounded by a parapet, and crowded with funeral monuments. The tomb-stones of the noble families occupy a large space in the middle of the field. The graves of the lower classes are every day covered with fresh flowers. The remains of the celebrated physician Wherloff lie under a triangular pyramid. "Not far distant," says Mangourit, "is a monument, representing a mother stretched upon the body of a beloved daughter; the scissars of fate cut a half blown rose, and the parent tree, stripped of its leaves, is torn up by the root. Just by is the tomb of the lover of the young lady. The sculptor has succeeded in depicting the beauty and elegant figure of this youth. On one side of the monument we behold a superb oak; on the other, the oak is reversed, its branches are broken, its leaves fallen, and its seed scattered." There are here some tombs and sarcophagi of white marble; but the greater number are formed out of stones from the Hartz mountains.

There is at Hanover a society of natural history; the seminary for schoolmasters; the female school of industry, conducted by Madame Klockenbrigg, in which some excellent pieces of embroidery are executed, and sold at a very high price.

Hanover formerly carried on manufactures of various kinds, particularly linen, damask, printed cotton, tapestry, wax-cloths, stockings, caps, gloves, flannels, serges, tobacco, lace, gold and silver lace, and ribbands; but we have not been able to learn in what state these manufactures are at present. There is a cannon foundry at Hanover, situated on the glacis of the city. The retail shops of Hanover, and the ware-houses of cloths and of French silks, are well supplied; English cloths and cottons a so abound.

The environs of Hanover are very beautiful. The city looks well at a distance with its four steeples, its houses intermixed with poplars and lime-trees, and its rural suburbs. The irregular assemblage of religious monuments, plain and handsome palaces, Gothic buildings, small wooden houses, churches painted of various colours, and arbours of different shapes and sizes, have a very singular effect. The windings of the Leine are very agreeable, and the triple row of lime-trees planted along its banks, which are covered with rose bushes and sword-grass. The windings of the Leine are, however, artificial. The springs near the fortifications not being sufficient to fill the ditches, a canal was cut in a serpentine direction, to the distance of about three kilometers above the city. This canal now conveys the provisions to the capital. In order to prevent the river from flowing back to its former bed, and to relieve it when too full, a large barrier, about 2 kilometers long, has been built of gray stone, so as to allow the surplus waters to flow into its former channel by three long dams. This work is admirably and solidly executed.

The principal promenades at Hanover are the garden of Madame La Baronne de Decker, the garden of Count Field Marshal Walmoden, Montbrillant and Herrenhausen, the country seat of the Electors of Hanover. The approach to Herrenhausen is by a long avenue of lime-trees. The castle is by no means a handsome building, and the grounds are laid out with the greatest uniformity. The water works are good, and before the central basin is a neat rural theatre. The orangerie, which formerly served as a ball room to the court, is a very long hall, decorated at every twelve feet with copies of ancient busts. It contains some fine orange plants, placed in boxes surrounded with laurels, and cut into a pyramidal shape. The garden of Herrenhausen is extremely interesting to botanists, and is said to be surpassed only by that of Schoenbrunn. Population, 15,500, or 19,444 according to Tynna *Almanac du Commerce pour* 1811. East Long. 9° 42′ 55″, and North Lat. 52° 22′ 25″. See Mangourit's *Travels in Hanover*, passim; and Reichard's *Guide des Voyageurs en Europe*. tom. ii.

HANSE TOWNS, is the name given to a number of towns in Germany and the north of Europe, who entered into a league for the protection of their commerce. This association is supposed to have commenced in 1169. It was confirmed in 1226 and 1284, and a general assembly of the members was held every ten years.

Almost every trading town in Europe became ambitious of joining the league; but it seems to have been a fixed principle, that every town was excluded that was not situated on the sea, or on some navigable river.

In the year 1226, the Hanse Towns were 72 in number; and among these were Calais, Rouen, St Maloe, Bourdeaux, Bayonne, Marseilles Barcelona, Seville, Cadiz, London, Lisbon, Antwerp, Bruges, Rotterdam, Ostend, Dunkirk, Messina, Leghorn, and Naples.

The towns were distinguished into four classes, at the head of which were Lubeck, the capital of the league, Cologne, Brunswick, and Dantzic.

This powerful association was in its most flourishing condition about the end of the 14th and the beginning of the 15th century, and interfered, to a great extent, in the affairs of Europe. The jealousy, however, of the European princes induced them to withdraw the merchants of their respective countries from the league; and in a short time it was so much reduced, as to comprehend only the four principal towns of Lubeck, Cologne, Brunswick, and Dantzic. In 1803, the only members of the league were Lubeck, Hamburgh, and Bremen. What changes it is to receive from the recent revolutions which have taken place in Europe time only can determine. See COMMERCE, and DENMARK.

HARBOUR. See INLAND *Navigation.*

HARBOURG, or HAARBURG, is a town of Germany, in the kingdom of Hanover. It is situated opposite to Hamburgh, on the Seeve, near its influx into the Elbe. It is pretty strongly fortified, and is advantageously situated for carrying on a considerable trade. Great quantities of wood are cut in the neighbourhood, and sent to Holland and France. There is here a manufactory for bleeching wax, a refinery of sugar, and manufactories of starch, stockings, ribbonds, and hats. Two packet boats set out every morning and evening for Hamburgh, the distance of which is only seven miles. The harbour of Harbourg, which is called Lotz, is so deep, that the largest vessels from Holland and Friesland can enter it and deliver their cargoes. A ditch or canal, furnished with two sluices, has been cut from the Elbe to the castle, which greatly facilitates the navigation and trade of the town. Population of the town 3500.

HARDICANUTE. See ENGLAND.

HARE. See MAMMALIA.

HARELIP. See SURGERY.

HAREWOOD, is a small town of England, in the west riding of Yorkshire, and one of the most beautiful in the kingdom. It lies between Harrowgate and Leeds, in a fine, rich, and beautifully wooded country. The houses are almost all built uniformly, and covered with slate. Before we enter the town from the north is Harewood castle, on the west side of the road. It stands on the brow of the hill, and is a lovely ruin almost covered with ivy. It is esteemed a fine specimen of castellated architecture, and is described in the *Archæologia*, vol. vi. The gateway to Harewood house, the seat of Lord Harewood, is at the south end of the town. It is recently built, and is one of the finest pieces of architecture we have seen. The view of Harewood house, and the surrounding country from the top of the hill, at the southern gate, is unusually grand.

HARFLEUR, is an ancient town of France, in the department of the Seine. It was formerly called *Hareflotum*, *Harflevium*, and *Heriflorium*. It is situated on the small river Lezarde, at the mouth of the Seine, and was formerly the key of France on the side of England; but it has fallen into decay, in proportion as Havre has risen in importance. Its walls have been razed, its harbour choked with sand, its fortifications demolished, and its trade ruined. There are here small manufactories for lace, cotton, linen, and beer. Peuchet, in 1800, has stated the population at 4388; but Tynna, in the *Almanac du Commerce* for 1811, makes it only 1600. A work was published at Harfleur in 1720, entitled *Antiquités de Harfleur*. See ENGLAND, for an account of the siege of Harfleur.

HARIDI. See ACHMIM.

HARMATTAN. See GUINEA.

HARMONIÆ, in music, an interval so named by M. Henfling, whose ratio is $\frac{125}{128}$, $=21\Sigma+2$ m, and is the greater ENHARMONIC *Diesis*, which see.

HARMONIC ELEMENTS, or *Concordant Elements*, are the three smallest concords, viz. 3d, III, and 4th, each one of which singly is harmonious; so is the sum of every two of them, as 3d+III=V, 3d+4th=6th, and III+4th=VI; and so is the sum of all three, as 3d+III+4th=VIII; and further, this latter concord (VIII) may be added once, or any greater number of times, to itself, or to any one of the six concords above mentioned, and still a concord will result: thus, 2 VIII=XV; 3 VIII=XXII; VIII+3=10th; VIII+III=X; 2 VIII+4=18; 2 VIII+V=

XIX, &c. are all concords; and, except the *Unison* (I), there are in nature no other *concords*, or combinations of two sounds, which are agreeable and pleasant to the ear, and produce *beats* when slightly altered or tempered, but those derived in the manner above described. See Concord. (ϱ)

HARMONIC Sliders, are the contrivance of Dr Thomas Young, for exhibiting to the eye the effects of the undulations or *beats* of tempered concords, which he has described in the *Journals of the Royal Institution*, p. 261, and illustrated the same by a drawing, intended to represent the *beating* of the imperfect *unison*, whose ratio is $\frac{17}{18}$, $=50,46033\Sigma+f+4m$; but which being nearly as large as the elementary *semitone* and a discord, is very improperly called a *unison*, or a beating concord.

The following is Dr Young's own account of this invention: "The combination of undulations is of acknowledged utility in illustrating the phenomena of musical consonances and dissonances, and of undeniable importance in accounting for many of the phenomena of the tides. Each tide is an undulation on a large scale; and supposing the general form of the ocean, in consequence of the attraction of a distant body, to coincide with that of an oblong spheroid, as it is found by calculation to do, the section of the surface of each tide, if conceived to be unbent from the circular form, and extended on a plane, would form the harmonic curve: (Young's *Syllabus*, IV. 151. 155.) It is remarkable that the motions of the particles of the air in sound have been generally supposed in theory to correspond with the ordinates of this same curve, and that there is also experimental reason to believe, that the purest and most homogeneous sounds do in fact agree very nearly with the law of this curve. It is therefore by far the most natural as well as the most convenient to be assumed, as representing the state of an undulation in general; and the name of these harmonic sliders is very properly deduced from the harmonic curve.

By means of this instrument, the process of nature, in the combinations of motion which take place in various cases of the junction of undulations, is rendered visible and intelligible, with great ease, in the most complicated cases. It is unnecessary to explain here, how accurately both the situations and motions of the particles of air, in sound, may be represented by the ordinates of the curve at different points: it is sufficient to consider them as merely indicating the height of the water constituting a tide, or a wave of any kind, which exists at once in its whole extent, and of which each point passes also in succession through any given place of observation. We have then to examine what will be the effect of two tides, produced by different causes, when united. In order to represent this effect, we must add to the elevations or depressions in consequence of the first tide, the elevations or depressions in consequence of the second, and subtract them when they counteract the effect of the first: or we may add the whole height of the second above any given point or line, and then subtract, from all the sums, the distance of the point assumed below the medium.

To do this mechanically is the object of the harmonic sliders. The surface of the first tide is represented by the curvilinear termination of a single board, Plate CCLXXXVIII. Fig. 1. The second tide is also represented by the termination of another surface; but, in order that the height at each point may be added to the height of the first tide, the surface is cut transversely into a number of separate pieces or sliders, which are confined within a groove or frame, and tightened by a screw, Fig. 2. Their lower ends are situated originally in a right line; but by loosening the screw and moving the sliders, they may be made to assume any other form: thus they may be applied to the surface representing the first tide; and if the similar parts of each correspond, Fig. 3, the combination will represent a tide of twice the magnitude of the simple tides.

The more the corresponding parts are separated, the weaker will be the joint effect, Fig. 4.; and, when they are furthest removed, the whole tides, if equal, will be annihilated, Fig. 5. Thus, when the general tide of the ocean arrives by two different channels at the same port, at such intervals of time that the high water of one would happen at the same instant with the low water of the other, the whole effect is destroyed, except so far as the partial tides differ in magnitude. The principle being once understood, it may easily be applied to a multiplicity of cases; for instance, where the undulations differ in their dimensions with regard to extent. Thus, the series of sliders being extended to three or four alternations, the effect of combining undulations in the ratio of 2 to 1, of 3 to 1, of 2 to 3, of 3 to 4, may be ascertained, by making a fixed surface, terminating in a series of curves, that bear to those of the sliding surface the ratio required: and, by making them differ but slightly, the phenomenon of the beating of an imperfect unison in music may be imitated, where the joint undulation becomes alternately redoubled and evanescent. In Fig. 6. the proportion is that of 17 to 18, and the curvilinear outline represents the progress of the joint sound from the greatest degree of intensity to the least, and a little beyond it."

HARMONICAL Mean, is a term used by arithmetical and algebraical writers to express certain relations of numbers and quantities: but with which *musical* calculators will find that they need have little to do, any more than with the harmonical or *musical* proportions and progressions of the same writers. If two quantities $a$ and $b$ are given, then $\frac{2ab}{a+b}$ is said to be the *harmonical mean* between them; for example, between 2 and 6, the harmonical mean is $\frac{24}{8}=3$: between 5 and 9, it is $\frac{90}{14}=6\frac{3}{7}$. Dr Smith in his *Harmonics*, 2d edit. p. 125, shews, how to find the harmonical mean, among any number of quantities: see also p. 141, *Ibid.*

HARMONICAL or Musical Proportion, of arithmetical and algebraical writers, is said to obtain between three quantities, as $a$, $b$ and $c$, when $a:c::a-b:b-c$; and between four quantities, as $d$, $e$, $f$ and $g$, when $d:g::d-e:f-g$; and so 2, 3 and 6; and 1, 3, 2 and 6 are said to be in musical proportion: And several of these writers say, that if to the three terms above mentioned, "proportional terms are continued, there will arise an *harmonical progression*" or series: but in all these cases, the terms *harmonical* and *musical*, seem only *figuratively* applied. (ϱ)

HARMONICS, in music, besides being used to designate the science or philosophy of musical sounds, as Dr Robert Smith uses this term, in making it the title of his justly famous work on this subject, imply also certain derivative or dependent *new sounds*, which, under favourable circumstances, are generated and heard, along with every single musical sound, or accompanying every consonance of two such sounds, but with less intensity or loudness than the original, or *generators* of these new sounds; and in the latter case, of their production by a consonance, when they are called *grave* Harmonics, (see that article,) such new sounds are further distinguished, by not having a *fixed direction*, towards (or from) the sounding body, but, like the sensation called "a singing in the ear," they are alike heard in any direction to which the ear is turned; a property of these derivative sounds, which Mr John Gough first explained, we believe, in

Nicholson's *Journal*, 8vo. vol. iv. p. 2. The other kind of these new sounds, derived from a single sound, are called *acute* HARMONICS, which see. (ϱ)

HARMONICS, ACUTE, are phenomena attending a sounding string or pipe, &c. which were first noticed by Galileo, and subsequently by Peter Marsenne, M. Sauveur, M. Tartini, &c.: but Daniel Bernoulli first discovered the reason, and explained the theory of the acute harmonics, by shewing, that a sounding string, at the same time that its whole length vibrated a given note, might maintain subordinate vibrations of its *half*, its *third* part, its *fourth*, and its *fifth* parts in length; each of such vibrating parts impressing on the surrounding air independent pulses, the times of whose single vibrations are in the ratios 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$; and by which the original sound, or *generator*, would be accompanied by its octave or VIII, its major twelfth or XII, is double octave or XV, and by its major seventeenth or XVII; although only the XIIth and XVIIth, or octave of the fifth and double octave of the major third, had yet been described, among the acute harmonics attending a sound. And this great mathematician, although unable to contrive any experiment, by which the vibrations of the $\frac{1}{5}$ and $\frac{1}{4}$th part of the string might be evidently shewn to subsist along with the whole vibrations, yet he shewed, from the nature of the Taylorean or harmonical curve, that these subdivisions of a sounding string were not only alike possible, and even more probable to happen than those of $\frac{1}{3}$d, and $\frac{1}{5}$th; but that theory and probability were not against the happening of even more minute vibrating divisions of the whole string, as $\frac{1}{6}$th, $\frac{1}{7}$th, $\frac{1}{8}$th, $\frac{1}{9}$th, &c.: and that in the use of the trumpet, horn, and other sounding tubes or pipes, all these subdivisions of the whole vibrating column of air might be made, separated by nodes or points in the axis of the tube, in a comparative state of rest with regard to these inferior or harmonical vibrations, although moving to and fro with the velocity peculiar to the sound of the whole tube: and he inferred, with great seeming probability, that the parts of bells, and most other bodies yielding musical sounds, were in the same manner capable of subordinate or acute harmonic vibrations, along with those of their principal or gravest sound.

It was probably not until about the year 1765, after the very ingenious Mr James Watt of Birmingham had contrived his wheel monochord, that the acute harmonics of a vibrating string were produced in experiment, and some of them actually rendered visible to the eye; as is related by the late Dr Robinson, who, several years after, made a more extended and complete set of experiments on the same instrument which Mr Watt had before used; thereby fully confirming all that D. Bernoulli had theoretically advanced.

Some years after this, Mr John Isaac Hawkins of London, the ingenious inventor of the piano-forte with spirally coiled strings, and of the *claviole*, or finger-keyed viol, contrived an experiment, which seems to leave nothing to wish with regard to this very curious and interesting subject. A spirally coiled string, many feet in length, was prepared by winding a brass piano-forte bass wire closely round a steel wire about the size of a crow quill, and when removed therefrom, pulling it out, so that its spirals became considerably more open, comparatively, than those of a common cork screw, or the string was nearly in the state of being "cockled," as tuners call it, at equal distances, throughout its whole length. Along the side of a large wainscoated room, this spirally coiled string was stretched, over two bridges, near its extremities, and brought to such a degree of tension, as not to yield a sound, but leave its vibrations, when strongly twitched, plainly visible to the eye. The space between the bridges had previously been carefully divided, on the wainscoat, into numerous equal parts, and marked $\frac{1}{2}$; $\frac{1}{3}$, $\frac{2}{3}$; $\frac{1}{4}$, $(\frac{2}{4})$, $\frac{3}{4}$; $\frac{1}{5}$, $\frac{2}{5}$, $\frac{3}{5}$, $\frac{4}{5}$; $\frac{1}{6}$, $(\frac{2}{6})$, $(\frac{3}{6})$, $(\frac{4}{6})$, $\frac{5}{6}$, &c.; and if, when the whole string was vibrating, a slight obstacle was opposed to the vibrations of the string, opposite to any one of these divisions, like the edge of the feathers of a quill, held to touch it very lightly, or even if a sudden blast of air from the mouth were made on the string, opposite a division, the string instantly assumed all the subordinate vibrations proper to the aliquot division against which the obstacle or impulse was directed; and the eye and ear too, in many of the instances, could be gratified, by seeing these very compound vibrations simultaneously carried on by the whole string, and by its several aliquot parts, during several minutes, under favourable circumstances, many of the vibrations being slow enough to be counted, and their number in a given time ascertained and compared, by which every point of the theory of D. Bernoulli is in the fullest manner confirmed.

Thus an evident explanation is offered, of all the curious harmonic effects of several unison strings on the ÆOLIAN *Harp*, (see that article) when agitated by irregular gusts of wind: acting momentarily on the whole string, and on its different nodes, with sufficient force to excite *the determinate vibrations*, which the elasticity of the string, and its parts, *dispose them* severally to take; but all of which vibratory motions are so vastly quicker than the mere motion of the wind, that we cannot agree with Dr Matthew Young in thinking, that particular tones are excited, or kept up, by that means.

We have calculated the values of all the aliquot parts of a string or pipe (in Farey's Notation of Intervals) above the note of the whole string, viz. $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. as far as $\frac{1}{32}$, and deducted octaves, so as to bring them all within the compass of one octave; and the same, when arranged under their respective finger-key intervals, stand as follows, viz.

| | | |
|---|---|---|
| VIII | $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$, | |
| | $\frac{1}{31}$, | = 5 VIII — 28.11748 Σ — 2 m |
| VII | $\frac{1}{15}$, $\frac{1}{30}$ | |
| 7th | $\frac{1}{29}$ | = 4 VIII + 7th* + 6 12449 Σ + m |
| | $\frac{1}{7}$, $\frac{1}{14}$, $\frac{1}{28}$, | . . . 7th — 24.9472 Σ — 2 m |
| VI | $\frac{1}{27}$ | = VI′, = VI + 11 Σ + m |
| | $\frac{1}{13}$. $\frac{1}{26}$, | . . . VI — 22.58107 Σ — 2 m |
| 6th | $\frac{1}{25}$ | = 6th — 21 Σ — 2 m |
| V | $\frac{1}{3}$, $\frac{1}{6}$, $\frac{1}{12}$, $\frac{1}{24}$ | |
| 5th | $\frac{1}{23}$ | 5th + 9.46026 Σ + m |
| IV | | IV + 19 46026 Σ + 2 m |
| 4th | $\frac{1}{11}$, $\frac{1}{22}$, | . . . 4th + 27.25171 Σ + 2 m |
| | $\frac{1}{21}$ | = 4th — 13.9472 Σ — m |
| III | $\frac{1}{5}$ $\frac{1}{10}$, $\frac{1}{20}$ | |
| 3d | $\frac{1}{19}$ | . . . . = 3d — 9.27098 Σ — m |
| II | $\frac{1}{9}$, $\frac{1}{18}$ | |
| 2d | $\frac{1}{17}$ | . . . . = S — 3.46819 Σ |
| I | $\frac{1}{1}$ | |

Wherein the errors or temperaments of all these acute harmonic notes are set down; and hence we perceive clearly the reason why a sound is accompanied chiefly by its VIIIth, VIII + Vth, and 2 VIII + IIIrd, and rarely by any other of its harmonics, viz. because $\frac{1}{2}$ of the string is strengthened, or reinforced by four other octaves to it: the XIIth (or V) is re-inforced by 3 other octaves to it, and the XVIIth (or III) by two other octaves to it; and these three are the only *concords* to the whole string, that

* The ratio of this minor seventh being $\frac{5}{9}$, = 519 Σ + 10 f + 45 m.

are found among its numerous harmonics. The II and the VII, each with the reinforcement of an octave thereto, should, and accordingly are, next heard in the order of acute harmonics. The harmonic 6th, being a diatonic interval, viz. 6—ℰ, whose ratio is $\frac{16}{27}$, $=394\Sigma+8f+34m$, may perhaps, under very favourable circumstances, be heard as an acute harmonic: but when the very discordant nature of all the remaining sounds in one table, both with the generator and with all of its other harmonics, respectively, are considered, it seems very plain why these sounds, although momentarily produced by a gust of wind, or other impulse, *on the proper part of the string*, almost immediately die away, and cannot be maintained, as the VIIIth, XIIth, and XVIIth may be, and others, in less degrees. (ϱ)

HARMONICS, Grave. These are low sounds, of small intensity or loudness, which, if attentively observed by an experienced ear, will be heard to accompany every accurate or perfect consonance of two sounds, whose ratio is expressible in small numbers, whether the same may be composed of the Diatonic primes 1, 2, 3, and 5, or of somewhat larger prime numbers.

A grave harmonic of a different species from the above is also heard, whenever the Beats of an imperfect or tempered concord (see that article) exceed 12 or 13 in a second of time.

About the beginning of the last century, M. Sauveur considered the reinforcement of sound which must periodically take place, while we hear a consonance of two musical sounds, whose ratios are in small numbers, occasioned by the coincidence at short intervals of the pulses of the two sounds. These reinforcements he called *beats;* and, as Dr Robert Smith has observed, improperly confounded these, which are grave harmonic sounds, (because rarely occurring so seldom as twelve times in a second,) with the *beats* (of imperfect concords) properly so called, which can be separately heard, and distinctly counted, in every instance where the degree of temperament or imperfection is sufficiently small.

About the year 1754, M. Rameau and M. Tartini first made observations on the coincident pulses of consonances with small ratios; but each of the ten grave harmonics which the latter has mentioned, have been found by later observers to be an octave too high; that is, the new sounds really heard to result from the rapid coincidence of the pulses of the single sounds, are an octave lower with regard to these sounds than Tartini supposed; errors which few will wonder at, who have experienced the difficulty of avoiding errors of an octave, or sometimes more than one, in estimating sounds that are either very high or very low.

In 1807, Mr John Holder published a work on music, in which he attempted to build a good deal of the theory of composition and harmonical effect on these grave harmonic sounds, accompanying consonances as their "dependants;" but most of his speculations have failed, and many of them led to very absurd conclusions, owing to his having set up and used a defective or false rule, for assigning the grave harmonic of a given consonance.

It is the more necessary, therefore, to give here a true rule for finding the grave harmonic of any given consonance, viz. Find the vibrations made by each of the sounds of the given consonance in one second, divide these successively by the reversed terms of the given ratio of the consonance, and the quotient (in each case) will give the vibrations for 1″ of the grave harmonic; the ratio of which vibrations, to the vibrations of either of the given sounds respectively, will give the interval of the harmonic below such given sound.

If, for example, the major second CD were given in the middle of the scale, where the ratio is $\frac{8}{9}$, and the sound of the lowest note (on the tenor cliff line) makes 240 vibrations per 1″, then $\frac{9}{8}\times240=270$ is the vibrations of D, and $\frac{270}{9}=30$, or $\frac{240}{8}=30$, the vibrations of the harmonic note; and its interval below the lower note C is $\frac{30}{240}=\frac{1}{8}$, or 3 VIII; and below the upper note D is $\frac{30}{270}=\frac{1}{9}$, $=$ 3VIII+II. The principal intervals of the scale, and some others, calculated as above, have their grave harmonics shewn in the following Table, viz.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| $\frac{1}{2}$ | VIII | 480 | 240 | $\frac{1}{1}$ | 1 | $\frac{1}{2}$ | VIII |
| $\frac{8}{15}$ | VII | 450 | 30 | $\frac{1}{8}$ | XXII | $\frac{1}{15}$ | XXVIII |
| $\frac{5}{9}$ | 7′ | 432 | 48 | $\frac{1}{5}$ | XVII | $\frac{1}{9}$ | XXIII |
| $\frac{9}{16}$ | 7 | $426\frac{2}{3}$ | $26\frac{2}{5}$ | $\frac{1}{9}$ | XXIII | $\frac{1}{16}$ | XXIX |
| $\frac{3}{5}$ | VI | 400 | 80 | $\frac{1}{3}$ | XII | $\frac{1}{5}$ | XVII |
| $\frac{5}{8}$ | 6 | 384 | 48 | $\frac{1}{5}$ | XVII | $\frac{1}{8}$ | XXII |
| $\frac{2}{3}$ | V | 360 | 120 | $\frac{1}{2}$ | VIII | $\frac{1}{3}$ | XII |
| $\frac{3}{4}$ | 4 | 320 | 80 | $\frac{1}{3}$ | XII | $\frac{1}{4}$ | XV |
| $\frac{4}{5}$ | III | 300 | 60 | $\frac{1}{4}$ | XV | $\frac{1}{5}$ | XVII |
| $\frac{5}{6}$ | 3 | 288 | 48 | $\frac{1}{5}$ | XVII | $\frac{1}{6}$ | XIX |
| $\frac{27}{32}$ | 3′ | $284\frac{4}{9}$ | $8\frac{8}{9}$ | $\frac{1}{27}$ | XXXIV | $\frac{1}{32}$ | XXXVI |
| $\frac{8}{9}$ | II | 270 | 30 | $\frac{1}{8}$ | XXII | $\frac{1}{9}$ | XXIII |
| $\frac{9}{10}$ | II′ | $266\frac{2}{3}$ | $26\frac{1}{3}$ | $\frac{1}{9}$ | XXIII | $\frac{1}{10}$ | XXIV |
| $\frac{15}{16}$ | 2 | 256 | 16 | $\frac{1}{15}$ | XXVIII | $\frac{1}{16}$ | XXIX |
| $\frac{1}{1}$ | 1 | 240 | 0 | | | | |

The *first* column of the above Table shews the ratios of the given consonances; the *second*, the intervals expressed in numerals; the *third*, the vibrations per second, supposing the lower part to be the note on the tenor-cliff line of the stave; the *fourth* column contains the calculated vibrations of the harmonic note; column *five* shews the ratio, and column *six* the interval of this harmonic, below the lowest of the given notes or C; and columns *seven* and *eight* shew the same things with regard to the highest of the given notes.

For the sake of more ready comparison with Mr Holder's defective rule for calculating grave harmonics, the errors of which it seemed of some importance to place in as clear a view as possible, we have given above a far less simple rule for obtaining the ratios of the new sounds, with relation to either of their generators, than the one which we are now about to add, viz. The ratio of any given consonance above a bass or fundamental note being $\frac{a}{b}$, $a$ being the least term of the ratio; then $\frac{1}{b}$ is the ratio of the grave harmonic below the bass note, and $\frac{1}{b}$ the ratio of the same harmonic below the upper note of the consonance; which is too evident, from an inspection of the above Table, to need a particular example.

With regard to the other kind of grave harmonics, the results of *tempered* concords, which beat too fast to be separately counted or perceived: If, for instance, we were to consider the grave minor third $\frac{27}{32}$ in the above Table to be a tempered concord, we should have, by our fourth method in the article Beats, $240\times6-284\frac{4}{9}\times5=1440-1422\frac{2}{9}=17\frac{7}{9}$, the beats per second, or vibrations of this grave harmonic, being just double, or an octave higher, than those in the Table above, and so of others; but our limits will not admit of our enlarging further on this subject. (ϱ)

HARMONICA. See Musical Glasses.

HARMONY, in Music, is a term which appears to have completely changed its signification since the first use of it. The ancient Greek writers, who seem to have contemplated only the *succession* of sounds which we call Melody, (see that article,) attached to such successions as were pleasing and agreeable to the ear, the name of a woman celebrated among them. But in more modern times, when the *simultaneous* as well as the progressive effects of sounds on the ear came to be practised and considered by writers on this subject, the term *melody* was applied to successions of sounds, particularly to such successions as are on the whole pleasing, and the term harmony was transferred to the newly contemplated and pleasing effects of certain intervals, when their limiting sounds are heard together, viz. 1, 3, III, 4, V, 6, VI; VIII, 10, X, 11, XII, 13, XIII; XV, 17, XVII, &c.* whose ratios are $\frac{1}{1}$, $\frac{5}{6}$, $\frac{4}{5}$, $\frac{3}{4}$, $\frac{2}{3}$, $\frac{5}{8}$, $\frac{3}{5}$; $\frac{1}{2}$, $\frac{5}{12}$, $\frac{2}{5}$, $\frac{3}{8}$, $\frac{1}{3}$, $\frac{5}{16}$, $\frac{3}{10}$; $\frac{1}{4}$, $\frac{5}{24}$, $\frac{1}{5}$, &c. called CONCORDS. See that article.

The further progress of musical discoveries next shewed, that certain others of the simple intervals, as I, 2, II, IV, 5, 7, VII; 8, 9, IX, XI, 12, 14, XIV; 15, 16, XVI, &c.; or $\frac{128}{135}$, $\frac{15}{16}$, $\frac{8}{9}$, $\frac{32}{45}$, $\frac{45}{64}$, $\frac{9}{16}$, $\frac{6}{15}$; $\frac{64}{135}$, $\frac{15}{32}$, $\frac{4}{9}$, $\frac{16}{45}$, $\frac{45}{128}$, $\frac{9}{32}$, $\frac{4}{15}$; $\frac{32}{135}$, $\frac{15}{64}$, $\frac{2}{9}$, &c. are called DISCORDS, (see that article,) might be occasionally introduced among, or in the place of some of the concords above mentioned, without destroying, but, on the contrary, heightening the pleasure of their effect on an ear accustomed to this mixed harmony of concords and discords.

When this mixed harmony came to be practised on instruments having fixed notes, the pitch of which the performer could not alter, as the singer, violinist, &c. can their notes, it was further discovered, that each of the concords and discords abovementioned, admitted of alteration, in small and unequal degrees, without altogether losing their respective characters or effects, when heard together in chords; but the pleasing effect in composition of many of these chords, were sometimes even improved, by the alteration of a major comma, (c, or $\frac{80}{81}$;) and hereby another class of comma-deficient and of comma-redundant concords were introduced, as 3‵, 3′, III′, 4′, V‵, V′, 6‵, 6′, VI′, VIII‵, &c. and so of the discords, I‵, 2′, II‵, II′, IV‵, IV′ V′, 7′, VII‵, VII′, 8′, &c.

And in adapting music to only twelve fixed sounds, within each octave, the simple or numeral intervals above mentioned were found altered, in some instances, more than the major comma, but in more numerous instances, by less and very different degrees of alteration or attemperament, in order to render music played thereon tolerably agreeable to the ear. And hence it becomes necessary for the musical student to be aware of the distinctions, which we shall now proceed briefly to enumerate, viz.

*Artificial* HARMONY, implies a mixture of simple or untempered concords, and of discords in the chords, or between the notes that are heard together, in any piece of music.

*Equal* HARMONY implies, according to one class of writers, an equality of harmoniousness between the different *keys* of music, but which is more properly called EQUAL *Temperament*: See that article, and ISOTONIC. But ac-according to Dr Robert Smith, and others of our best writers on the subject, this term should be restricted to systems in which each of the six concords, 3, III, 4, V, 6, and VI, are so tempered, as to be equally and the most harmonious or pleasing amongst themselves, while 1 and VIII remain perfect. See EQUAL *Harmony*.

*Natural* HARMONY, according to Dr Busby, admits only of the harmonic triod, or common chord, $\frac{V}{III}$, in the accompaniments of a piece of music.

*Perfect* HARMONY, implies the use of perfect or untempered concords only, such as are produced by good singers, violinists, &c. when they perform full music in concert, and which, as Mr Farey has shewn, in the *Philosophical Magazine*, vol. xxvii. pp. 206 and 314, contains all its temperaments in the leaps or successive intervals of the melodies of the different parts, and none of such in their combined or simultaneous intervals of harmony, all of which are produced perfect, or without temperament. Mr Maxwell, in 1781, fully explained this system, as applicable to the violin, and made some attempts at applying the same to the organ, but without effect, (See MAXWELL'S *Scales*.) Several years afterwards, however, the Rev. Mr Liston completed his EUHARMONIC *Organ*, (see that article,) and, in 1812, published his *Essay on perfect Intonation*, wherein this curious and important system is fully explained. See LISTON'S *Scales*.

*Tempered* HARMONY, is such as must of unavoidable necessity be heard, in several or all of the concords, (and discords too,) in performance on the common or imperfect keyed instruments, having only twelve, or even a greater number of sounds in each octave. See TEMPERED *Systems*. (g)

HAROLD I. See ENGLAND.

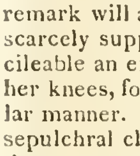
HAROLD II. See ENGLAND.

HARP, is a stringed musical instrument, which has gained much celebrity from the estimation in which it was held among the ancients. Though the harp be of eastern origin, it has been the subject of animated controversies, whether the instrument was actually known to the Greeks and Romans in any shape analogous to its present form. It appears most probable, however, that they were not ignorant of it, and that some of the instruments passing under different names, whose elementary parts and principles are the same, should be considered only as modifications of each other. But the researches of late travellers have brought more interesting objects to view than those exciting dry disputations. Mr Bruce, in visiting the catacombs of the Theban kings, who are supposed to have been cotemporaries with David, king of the Jews, 1000 years before Christ, discovered two paintings of the harp in fresco, each played by an old man standing, clothed in a wide tunic, and having his head shaven. One has thirteen strings, but wants the upright, or that piece of the frame next to the longest; and the sounding board is of a conical form, enlarging below in proportion to the length of the string. The other has eighteen strings, and seems to be a harp formed of similar materials; but the distribution of the parts is different, and the lower strings are united to the bass, not to the sounding board. Both are represented as being played in the same manner, and by men in the same position. After describing the ornamental parts, Mr Bruce affirms, that "it would be even now impossible either to construct or finish a harp of any form with more taste and elegance." However, while preparing to make further researches, he could not prevail on his conductors to wait any longer in the catacombs; "with great clamour and marks of discontent, they dashed their torches against the largest harp, and made the best of their way out of the cave, leaving me and my people in the dark; and all the way they went, they made dreadful denunciations of tragical events that were to follow their departure." It is to be inferred from the figures, that each harp is above six feet high. The purport of Mr Bruce's description, which is much more copious than quoted here, has been strangely misunderstood, though it must be admitted that this was

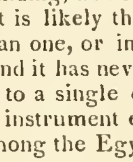
* No limits have yet been assigned to this harmonic or concordant series, found by adding *seven, fourteen, twenty-one*, &c. to each of the first seven numeral terms; or by multiplying the terms of the first seven ratios by $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, &c. to produce the ratios of concords in the successive octaves.

partly owing to his own imperfect communications to Dr Burney. Whence it has been asked by Mr Jones, "Whether the Theban harp originated in a phantasm?" and even Mr Browne, the African traveller, says, while visiting the catacombs of Thebes, "I particularly observed the two harpers described by Bruce, but his engraved figures seem to be from memory." We cannot entirely solve these difficulties; but had those who have spoke most positively on the subject, referred to the first volume of Mr Bruce's Travels, instead of Dr Burney's History of Music, they would have obtained more distinct ideas of it. However, during the late expedition of the French, the sepulchres of the kings of Thebes were again visited; and M. Denon acquaints us, that in a "fourth chamber, there is a figure clothed in white, playing on a harp with eleven strings; the harp sculptured with ornaments of the same tint, and consisting of the same wood as ours are now made." On recurring to Plate CXXXV, of the large edition published by the French government, we observe two figures playing on harps, one represented with 27 strings, the other with 33; and also a third, apparently in miniature, touching a harp with only 9. The first of these is a person standing, clothed in a robe tucked up between the legs; the second is a naked woman on her knees. Both harps are of elegant workmanship, ornamented with sphinxes: and, instead of being triangular, the upright is bent into a curve along with the base. Neither of them bears any resemblance to the first or triangular 13-stringed harp of Mr Bruce, but his second is formed after the same fashion. From all this it is to be inferred, that the harps represented by Denon were seen in a chamber different from that visited by Bruce, and most probably the same remark will apply to what is said by Mr Browne. We can scarcely suppose it possible that there could be so irreconcileable an error as to mistake a naked woman sitting on her knees, for a man standing, and clothed after a particular manner. Farther, it is likely that Denon was in more sepulchral chambers than one, or in different recesses of the same apartments: and it has never been said that these paintings were confined to a single excavation only. The harp, therefore, was an instrument evidently brought to a degree of perfection among the Egyptians, while Greece was yet in its infancy.

In order to facilitate the understanding of illustrations which may be given of the more ancient construction of the harp, we shall briefly describe its present structure and compass. This instrument is now, as it has always been, of a triangular shape; and the gradual elongation of the strings also produces their general arrangement in a corresponding triangular outline. One side of the triangle is formed into a large expanding sounding-board, on the construction of which much of the intonation depends. The whole strings are united to it. A base whereon the harp rests solidly is formed at the lower angle; and here are placed several pedals, which, by an ingenious mechanism, produce flats and sharps. It is commonly, but not always, strung with 35 strings, the lowest equivalent to double A or



of the piano forte, and the highest note equivalent to double G, or



of the same instrument: thus the compass which is arbitrary, is considerable. However, most of the modern harps have seven or eight strings of the bass, to increase it still farther, which, in our opinion, is a very questionable expedient, rendering the total number 43. But this is considerably augmented by the operation of the pedals. These are usually seven in number, and are designed according to the effect they produce: the E pedal changes E flat, in which the harp is now invariably tuned into E natural; the F pedal changes F natural into F sharp, and the G pedal changes G natural into G sharp. In some instruments, the change by simple pressure is to the extent of a semitone; in others of the latest construction, by increasing the pressure on the pedal, the strings affected by it are sharpened another semitone. Three notes are thus obtained from a single string. The action of the pedals, as their name implies, is operated by the feet; four being appropriated for the right foot, and three for the left. All the strings are of catgut, except seven or eight of the lowest, which consist of silk covered with silver wire, as the lowest strings of the violin and violoncello. In the harp the C's are coloured red, and every F is blue, in order that they may be more readily distinguished by the performer; the others are of the ordinary yellowish white of catgut. The whole instrument of the largest size is nearly six feet high, and in Britain costs 100 guineas.

The name of the harp is said to be of Saxon origin; and we can probably trace it to the tenth century; for the author of the life of St Dunstan, who is supposed to have been a cotemporary, observes, "Sumpsit secum ex more citharam suam, quam lingua paterna *hearpam* vocamus." (*Acta Sanctorum*, tom. iv. p. 350.) Venantius Fortunatis, a continental author of the seventh century, uses this expression, "Plaudat tibi, Barbarus *harpa*;" which has been conjectured to apply to Britain. The harp is called *Telyn* in Welsh, and *Clarsach* in Irish.

We can scarcely ascertain, at the present day, under what form this instrument first appeared in these kingdoms; but it was undoubtedly well known in Wales and Ireland. Nor were the English and Scotch strangers to it; though its music was less cultivated among them. An ancient Irish harp which has had 28 strings, and is 32 inches high, is reported to have belonged to a certain king, Brian Boromh, who was killed in battle in the year 1014. His son having retired to Rome, presented his father's harp and crown to the Pope, on purpose to obtain absolution for a murder he had committed; and both remained in the Vatican, until the harp was sent by the reigning Pope to King Henry VIII. and, after passing through the hands of various owners, it was, in 1732, deposited in the library of Trinity College, Dublin. That such an instrument was actually at Rome in the time of Adrian IV. between 1154 to 1159, seems established from record; but the presumption of this particular harp remounting to so very ancient a period of Irish history as 1014, rests only on a very slight foundation. Two harps of considerable antiquity have lately been seen in Scotland; one of which, in size, appearance, and structure, narrowly resembles the Irish harp. Both are preserved in the family of Robertson of Lude; and the history of the oldest can be traced to about the year 1460. It is 38 inches and a half in height, and has had 30 pins, originally of brass, with as many corresponding string holes, all neatly ornamented. The other is ascertained to have belonged to Queen Mary, and is altogether of a more modern fashion and smaller dimensions. It is 31 inches high; the sounding board is only 11 inches and a half broad at the base, whereas that of the former is 16; and there have been 28 strings, the shortest two inches and a half long, while the second and third of the Caledonian harp have not exceeded two inches. The longest string of the latter is only 21 inches and a half in length; that of Queen Mary's 24. It is said that Mary having carried this instrument along with her in an excursion to the Highlands, in the year 1563, presented it to a lady who was married into the family of Lude. It was formerly ornamented with the Queen's portrait, and the Scotish arms executed in gold, of which and other jewels it was despoiled during the rebellion of 1745.

None of the harps we have named exhibit pedals, which are reported to have been invented by M. Simon at Brussels, between 1750 and 1760. The principal object of the pedals is to diminish the number of strings; for although the most grateful music certainly does not consist in the greatest variety of notes, a considerable range becomes necessary to adapt an instrument to all compositions. Probably the strings of the harp were originally very few; indeed in this respect its structure is altogether arbitrary; and the number has been different at different eras and in different countries, as is proved by the examples already given. In France, a harp is spoken of in the 14th century with 25 strings: in England, one of the same century, or perhaps earlier, is represented with only 14, and one of the 16th is described to have had 33. It will be observed, that we have hitherto spoken of the strings of a harp with a single row: and they have even been greatly augmented beyond these numbers; but some ingenious mechanics have adopted a second or third row, for the purpose of multiplying the notes. Galileo, in a work written about the year 1582, speaks of harps with 54, 56, or 60 strings, used in Ireland, from which island the harp of Italy was introduced; and having obtained one from an Irish gentleman with two rows of strings, consisting in all of 58, he found they were disposed in the same manner as a harp of the same construction introduced a few years previously into his native country. Mersenne represents a harp with 75 strings, arranged in three rows. The Welsh are said to have had one similar; and the number has sometimes been increased to 100. The introduction of pedals, however, has superseded the necessity of such a variety of single notes.

The harp was generally strung with brass or steel wire. The western Islanders or Highlanders of Scotland had a particular kind of harp strung with the tendons of animals; and the Welsh sometimes used horse hair. We are quite uncertain regarding the real compass of the most ancient harps, or the manner in which they were tuned.

Diodorus Siculus says, that the instruments used by the Gallic bards resembled lyres; but it is doubtful whether or not this was the harp, and there is very little certainty regarding its origin in these islands. Its most ancient appearance is of very rude and imperfect form, though considerably diversified; but the strings seem invariably to be very few. Performers too are frequently represented as holding it in one hand while they are playing with the other. Mr Ledwich conceives it was introduced into Ireland in the fourth or fifth century, from the close connection of the Irish "with the Saxons and other rovers from the Baltic shores, who conjunctly ravaged the coasts of Gaul and Britain in those ages." In Scotland it appears sculptured on a very ancient monument near the church of Nig in Ross-shire, engraved by Mr Cordiner; and ancient sculptures or drawings of it are to be seen in England, though frequently with a reference to religious matters. Probably the harp was not used in Scotland to any extent, though it was known to individuals; and, subsequent to the date of the instruments before alluded to, there is recorded, in a curious account of an insurrection in 1594, a prophecy regarding the Earl of Argyle's harp being heard in the district of Buchan. In Ireland and Wales, the case was different; for the harp seems to have been carefully and extensively cultivated; at least in as far as the rudeness of the people would admit. Giraldus Cambrensis bears the most unequivocal testimony to their powers, and the quality of their music; affirming, that the Irish were incomparably the most skilful of any nation in music, and not of that dull and languid description to which the inhabitants of Britain were accustomed, but what required much rapidity in execution. Probably their abilities greatly declined; for we afterwards find it observed, that Crusus was to be considered as almost the only harper about 1584. In Wales still greater attention was paid to the instrument, and Giraldus is alike lavish of his praises on the performers. There was even a triennial congress, whither all the most distinguished musicians repaired to compete in skill; and there is still preserved a small silver harp, about six inches and a half high, which was conferred on the victor. The privilege of bestowing this badge seems to have been vested in the family of Mostyn. The congress was held by royal authority at some of the royal residences in Wales; and, besides others, we read of a mandate issued by Henry VIII in 1523, for the purpose of instituting order and government among the professors of poetry and music, and regulating their art and profession according to the old statute of *Gryffyd ab Cynan*, Prince of Aberffraw. Another was assembled by order of Queen Elizabeth, in 1568, at Caerwys, where degrees were to be bestowed according to merit; but those not qualified were enjoined to betake themselves to some honest livelihood and profession, under pain of being apprehended and punished as vagabonds. At that time 55 degrees were conferred, 17 for vocal, and 38 for instrumental performance. At length the institution fell into total disrepute, and the harp seems to have become obsolete; for a traveller in Wales between 1780 and 1790 observes, that the only harp he heard in all the country was at Conway. An attempt was lately made to revive the Eistedfodd, as it was called, after several considerable intervals of repose; and at a meeting, one of the last that was held, 12 minstrels attended, (*Gent. Mag.* vol. lxii. p. 96) And, we believe, a similar congress was unsuccessfully attempted in Ireland during the year 1785, where only indifferent performers appeared. The art of playing upon the harp, however, is at present considered an elegant accomplishment, particularly in youthful females; and it has gained much ground in Britain within these twenty years. At present it is sometimes to be heard at public concerts; and we have understood, that the combination of a number of harps has lately been introduced into an orchestra in Paris. The harp, however, can never be more than a chamber instrument: it labours under many defects, notwithstanding all the modern mechanical improvements which it has received; whence we may reasonably infer, that the excellences of the ancient Welsh and Irish music, as performed upon that instrument, are highly exaggerated. Complicated music does not belong to an uncivilized people. Their tunes are but a kind of whining chant; and the further we ascend with those best known to us, they are found the more inharmonious. Yet enthusiasm can figure any thing, as at this day we see savages dance in extacy to beating on a wooden drum. The minstrels too, who in modern times have been regarded with admiration, and who held a prominent part in the musical performances of old, were nothing but a worthless vagrant race, generally proscribed as vagabonds. See Galileo *Opere*, tom. iii.; Mersennus *Harmonicorum*, p. 68; *Giraldus Cambrensis*, cap. 12; Denon's *Voyages*, tom. i. p. 237, tom. ii planche 135; Bruce's *Travels*, vol. i. p. 133; Carter's *Specimens of Sculpture and Painting*, vol. ii. p. 11, 16, 42. 43; Cordiner's *Antiquities of Scotland*, plate 1; Walker's *Memoir of the Irish Bards*; Jones' *Relics of the Welsh Bards*; Gunn's *Historical Enquiry*; Evan's

HARQUEBUSS. See GUNMAKING.

HARRIS, JAMES, one of the most celebrated philologists of modern times, was born at Salisbury on the 20th of July, 1709. His father was a gentleman of independent fortune, of the same name, and his mother sister to the Earl of Shaftesbury, author of the *Characteristics*. He was educated in early life under Mr Hele, at the grammar school of his native city. At the age of 16 he was removed to Oxford, where he passed the usual number of years as a gentleman commoner of Wadham college, and was then entered at Lincoln's Inn, for the purpose of studying law as a part of liberal education. Having, in his 24th year, succeeded, by the death of his father, to his patrimonial property, he followed more completely his own inclinations, by devoting himself to the study of Grecian and Roman literature. He studied profoundly the philosophical writings of the ancients, and acquired a great partiality for the philosophy of Aristotle. His studies were conducted in his house at Salisbury, where his habit was to rise very early, for the purpose of prosecuting them in quiet, and to mingle occasionally through the day with the society of that city. He also officiated with great credit as a magistrate for the county of Wilts.

His first work, which appeared in 1744, was a volume containing three treatises; the first on art, the second on music, painting, and poetry, and the third on happiness, which contained some sound moral observations, and were adorned with elegant literature. In 1745 he married Miss Clarke, daughter of John Clarke, Esq. of Sandford in Somersetshire, by whom he had five children. Two of these died young; but two daughters and his son, now Lord Malmesbury, survived him.

Persevering in his favourite studies, he published, in 1751, his *Hermes, or Inquiry concerning Universal Grammar*—a subject to which his attention had been particularly directed by the *Minerva* of Sanctius. The *Hermes* was received with great applause, and placed the author in the highest rank of philosophical grammarians. But the credit which that work derived from having remained so long unchallenged. was at last shaken by the severe animadversions on it, which were published by Mr Horne Tooke, in his celebrated *Diversions of Purley*. This author has convicted Mr Harris of some incongruities; and has, in his turn, laid the world under deep obligations, by furnishing valuable materials for the correction and improvement of dialectic science: (See our article GRAMMAR, *passim.*) How Mr Harris would have felt had he lived to see himself so contumeliously treated as he is in the work now mentioned, is a question of personal patience, and neither justice nor good nature would delight in seeing any man of worth subjected to such a trial. But now that both of these authors are out of the reach of each other's opposition, as well as the partiality of their respective friends, neither of them appears sufficiently perfect to be adopted as a guide, and both are too respectable to be treated with contempt. Mr Harris had the undoubted merit of delighting such of his cotemporaries as took an interest in the subject. Although, when the import of the words in which his theories are expressed is severely scrutinized, we find them sometimes inconsistent; candour will still endeavour to appreciate the truths which they imperfectly express, and will not fail to find out, in the most unmeaning phrases, some just views which the author aimed to unfold. The difficulty of expressing new opinions on a new subject, in which language is employed in explaining its own nature, may have given rise to some faults in the theoretic dissertations of Mr Harris; but it is no small praise, that his errors required the acuteness of Mr Tooke to discover them, and it must be acknowledged, that the latter has not done justice to his merit. The works of these two authors may be profitably employed for correcting one another, and extending jointly the limits of the science. The views of Mr Harris are on the whole pleasing; and the manner in which they are exhibited, shews an elegant and scientific mind. His writings are not disfigured by wanton satire, expressions of personal antipathy, or querulous moroseness, paradoxical turns of phrase, or an inclination to sport with the feelings of one part of his readers, and carry off by force the admiration of others. Trusting to the interesting nature of his subject, he does not go in quest of spurious sources of animation. After bestowing much labour on the investigation of his subject, he presents his readers in a respectful manner with the best views which he is able to form. He cherishes throughout a spirit of philosophical inquiry, free from any character of extravagance, and possessed of an admirable tendency to generate a placid satisfaction, and a chaste consistency of feeling.

From the time of his marriage till the year 1760, Mr Harris lived entirely in Salisbury during winter, and retired in the summer to his country house at Durford, in the neighbourhood of that city. Besides attending to the pursuits of literature and the duties of a magistrate, he devoted an adequate proportion of his time to the sacred task of superintending the intellectual and moral education of his children; and he zealously promoted a refined taste in music and other elegant pursuits in the circle of society in which he lived.

In 1761, he was elected member of parliament for the burgh of Christchurch, which seat he retained till his death. In the following year, he was made one of the lords of the admiralty; and in two years after a lord of the treasury; In 1765, he went out of office with the ministry with which he was connected. In 1774, however, he was, much to his gratification, appointed secretary and comptroller to the Queen.

During the hours of leisure which the duties of public life allowed him, he prosecuted, with great regularity, his literary labours. In 1774, he published his *Philosophical Arrangements*, a work in which he displayed all his former admiration of the Peripatetic logic, and combatted the doctrines of chance and materialism, animated by a zealous re-

---

HARRISBURGH, originally LOUISBURGH, the seat of government in Pennsylvania, is situated on the north-east bank of the Susquehanna river. It is regularly laid out, and contains, perhaps, six hundred houses; of which some are neat and convenient. The houses are generally built of brick or stone. Harrisburgh is likewise the seat of justice for Dauphin county; and has a courthouse and gaol. The former is nearly 100 feet long, and half as many wide, with a cupola and bell. The legislature, for the present, convene in this building; the permanent state house not yet having been erected. There is here a beautiful bridge over the Susquehanna; and the surrounding country is picturesque. The population of Harrisburgh is something upwards of two thousand. They vend merchandise to the country people, and manufacture leather, hats, nails, &c. The lumber used in building is generally brought down the Susquehanna. There is a German church in the town; a presbyterian congregation, respectable for numbers and character, worship in the court-house. Harrisburgh is 107 miles W. N. W. from Philadelphia; 53 W. S. W. from Reading; and 17 E. N. E. from Carlisle. Lat. 40° 16′ N. (E. H. CUMMINS, A. M.)

gard for the happiness of mankind,—an object of which, many who have espoused the opposite side of these questions, have betrayed an unfeeling neglect, by the style and manner in which they have published their opinions.

In 1780, the same year in which he died, he printed for the use of his circle of private friends a work, which was published immediately after his death, entitled *Philological Inquiries*, containing a popular summary of the conclusions to which the philosophical investigations of the ancients conducted them, accompanied with pleasing illustrations and examples. It contains also some affectionate expressions of personal attachment to his friends, and, on the whole, furnishes a good example of talents retaining at a very advanced age their former vigour, as well as of candour and benevolence continuing undiminished. His health, however, was now much impaired, and he died on the 22d of December 1780, in the 72d year of his age, beloved and regretted by all who knew him.

His private character appears to have been thoroughly amiable. With a mind well disciplined to severe thought, he united an unrestrained freedom and cheerfulness of character, which inclined him to take a ready part in all the subordinate interests and common amusements of life. He exhibited on all occasions a temper the most humane, gentle, and forgiving. As a critic, he was candid and indulgent; and, with a sagacity which enabled him to discern deformities, he had a sense of justice and of gratitude which made him chiefly delight in acknowledging literary beauties. Those who dispute the accuracy of some of his conclusions, would do well to copy the tender solicitude which he expressed for the general interests of his species, and the delicacy with which he communicated to the world the fruits of his researches.

His son Lord Malmesbury, published an edition of his works in two quarto volumes, to which he prefixes a brief account of his life. He seems to value his father's memory, chiefly for the steady resistance which he made to those opinions on general subjects which have prevailed in modern France, and which, from their harsh collision with previously existing systems, and, as he thinks, from their intrinsic repugnance to the interests of society, gave rise to that political discord, and those consequent ravages of war, with which Europe has in our age been visited. HARRISON'S Temperament of the musical scale. The late Mr John Harrison, who laboured so successfully in improving chronometers, about the year 1748, conceived the idea of a tempered system of intervals, in which the interval of the major third should bear the same proportion to the octave as the diameter of a circle to its circumference. On reference to Mr Farey's corollaries regarding regularly tempered douzeaves, in the *Philosophical Magazine*, vol. xxxvi. page 374, the temperaments and wolves of this system may easily be calculated, and these applied to the respective intervals will stand as follows, viz.

| | | | |
|---|---|---|---|
| 11 of the Vths, viz. on C, G, D, A, E, B, ♯F, ♯C; and on F, ♭B, and ♭E, each of the value . . . . . . . . . . . | 354 69244Σ+7f+31m | = | 3901.61684Σ+77f+341m |
| And the wolf fifth on ♯G, . . . . . . . . . . . . . . . . . . . . | | = | 382.38316Σ+ 7f+ 30m |
| Make 7 octaves, each . . . . . . . . . . . . . | 612Σ+12f+53m | = | 4284 00000Σ+84f+371m |
| 8 of the IIIds, viz. on C, G, D, A, and E; and on F, ♭B, and ♭E each, | 194.77762Σ+4f+17m | = | 1558.22096Σ+32f+136m |
| And 4 wolf IIIds, viz. on B, ♯F, ♯C, and ♯G, each . . . . . . . . . . . | 222.44476Σ+4f+19m | = | 889.77904Σ+16f+ 76m |
| Make 4 octaves, each . . . . , . . . . . . . . | 612Σ+12l+53m | = | 2448.00000Σ+48f+212m |
| 9 of the 3ds, viz. on A, E, B, ♯F, ♯C, and ♯G; and on D, G, and C, each | 159.92268Σ+3f+13m | = | 1439.30412Σ+27f+117m |
| And 3 wolf 3ds, viz. on F, ♭B, and ♭E, each . . . . . . . . . . . . . . . . . . | 132.23196Σ+3f+14m | = | 396.69588Σ+ 9f+ 42m |
| Make 3 octaves, each . . . . . . . . . . . . . . | 612Σ+12f+53m | = | 1836.00000Σ+36f+159m |

The fourths, minor sixths, and major sixths, complements to the above Vths, IIIds, and 3ds, will be each of them as much tempered *sharp* as these are tempered *flat* respectively. It appears, from the preface to the first edition of Dr Smith's *Harmonics*, that Mr Harrison adjusted frets on the finger-board of a base viol according to this system, and that Mr Harrison declared himself much pleased with the "extremely fine harmony" of its consonances. It is, however, to be regretted, that Dr Smith did not himself hear, and give us his opinion, on the harmony thus produced by Mr Harrison. Several years afterwards, Mr Maxwell, as he informs us p. 249 of his "Essay on Tune," did hear and attend to Mr Harrison's performance on his six-stringed viol thus fretted, and Mr Maxwell by no means approved the harmony thereof. In 1775 Mr Harrison gave some account of his musical scale in his work on chronometers. (*ς*)

HARROW. See Agriculture.

HARROW on the Hill, is a village of England in Middlesex. The hill on which it stands is the highest ground in the county, and has an insulated appearance, being visible from great distances almost in every direction. This village is celebrated for its free school, which is now universally allowed to be one of the best seminaries in the kingdom. It was founded in 1592 by John Lyon, a wealthy yeoman of Preston in this parish. He allotted 20*l.* for two exhibitions to Caius College, Cambridge, and two to Oxford. This sum, however, has been doubled. The number of scholars at Harrow school is generally about 150. The rent of Mr Lyon's estates amounted lately to 669*l.* which is disbursed in paying the salaries of the masters, the exhibitions already mentioned, in educating poor children, relieving decayed house-keepers, repairing roads, &c. The church of Harrow, which contains several sepulchral monuments, is partly of ancient architecture. The lower part of the tower, and the columns between the nave and aisles, are supposed to have been built by Lafranc in the time of King William I.

The view from Harrow is very fine. Towards the east it is terminated by the metropolis; to the south by the Surrey hills; to the north is a view of Harrow Weald, with the village of Stanmore and Bentley Priory, the seat of the Marquis of Abercorn: and to the south-west is seen Windsor Castle, with a considerable part of Berkshire and Buckinghamshire. On the top of the hill is a well of excellent spring water, which is never dry even in the hottest summers. In 1811 the number of houses in the town, including the hamlets of Roxeth and Sudbury, was 283, and the population 1689. See Lyson's *Environs of London*, 4to. vol. ii.

HARROWGATE is the name of a celebrated watering place in England, in the West Riding of Yorkshire. It is situated in the forest of Knaresborough, about three miles south-west of the town of Knaresborough. The village is divided into High and Low Harrowgate, and consists principally of the inns and lodging houses for the accommodation of the numerous invalids who flock hither from every part of the united kingdom. Before the mineral springs were discovered, Harrowgate was a miserable hamlet; and it was not till 1687 that the first inn, called the Queen's Head, was erected. Before the year 1700, there were three good inns in the village, and it now contains eight spacious inns, viz. the Granby, the Dragon, the Queen's Head, and the Hope Tavern, at High Harrowgate; and the Crown, the White Hart, the Crescent, and the Bell, at Low Harrowgate; beside numerous lodging houses for those who wish for a more retired life. The Crown Inn at Lower Harrowgate, is a long row of plain buildings. The public hall or promenade is a large and elegant apartment, with an organ at one end. The Crescent is situated behind the Crown Inn in a less public situation.

The chalybeate springs, which are two in number, are both at High Harrowgate. The oldest of these, called the Old Spa, was discovered by Captain Slingsby in 1571, and is situated opposite the Granby Inn. It was covered in 1786 with an elegant dome, erected at the expense of Lord Loughborough, who also laid out an extensive plantation on his property here, which affords an agreeable shade to a walk eight feet broad, and two miles long. The other chalybeate spring is about half a mile west of the Old Spa, and is called the Tewit well, from the birds called tewits which frequent it.

The sulphureous springs, which are two in number, are situated at Lower Harrowgate, and are inclosed with stone buildings, one of which, near the Crown Inn, is a temple of the Tuscan order, 24 feet in diameter, consisting of a cupola, supported by 12 columns. The water of this spring is extremely offensive to the smell and the taste. When taken in small quantities, it is an excellent alterative; but when copiously drunk, it is strongly purgative, and has been found very efficacious in cutaneous diseases and scrophula, in destroying worms, in removing chronic obstructions, and in all disorders of the stomach. The second sulphureous spring was discovered in the gardens of the Crescent in 1783. It is of an intermediate quality between the chalybeate and sulphureous waters.

The buildings at Harrowgate are rapidly increasing every year. It now contains more than 1500 inhabitants. See *Beauties of England and Wales*, vol. xvi. p. 652.

HARTLEPOOL, a town of England, in the county of Durham, is situated on a promontory nearly encircled with the German Ocean, which forms a capacious bay on the south side of the town. It is built on the western slope of a hill, and consists of a principal street, a back street, and several cross streets. The chief buildings are, a chapel of irregular structure, a town hall, a free school, and a custom house. The town is surrounded with ancient fortifications, which are described at great length by Hutchinson in his *History of Durham*. Hartlepool is much frequented in the summer months for bathing, but at other seasons it is inhabited principally by the fishermen. Within a few yards of the Watergate, a chalybeate spring has lately been discovered. It is covered by the sea at low water. About five miles north of the town are the singular rocks called the Blackhalls: (See DURHAM.) A life boat has lately been established here by subscription. On the moor near the town are two batteries mounted with cannon, beside an intrenchment. In 1811 the township contained 242 houses, and 1047 inhabitants. See Hutchinson's *History of Durham*, and the *Beauties of England and Wales*, vol. v. p. 119.

HARTLEY, DAVID, was born on the 30th of August 1705. He was the son of a respectable clergyman, vicar of Armley, in the county of York, where he died, leaving behind him eight children. The subject of this article was brought up by a Mrs Brooksbank, who lived near Halifax. He received the first rudiments of his education at a private school, and his academical education at Cambridge. He was admitted at Jesus College at the age of fifteen years, and was afterwards elected a fellow of that society, and took the degree of M. A. He was originally designed for the church, and proceeded for some time in his thoughts and studies towards that object; but he was restrained by some scruples, which made him reluctant to subscribe the thirty-nine articles. He continued, nevertheless, a member of the church of England, conforming to its public worship. This he did upon the principle, that the church of England maintains, in substance, the practical doctrines of Christianity, and that it was not incumbent to separate himself from its communion on account of some articles, which he regarded as speculative and abstruse. Having, it would appear, from conscientious scruples, relinquished the profession of his first choice, he applied his talents to the medical profession, in which he arrived at considerable eminence for skill and industry, but still more for philanthropy. He exercised the healing art with equal attention and fidelity to the poor and the rich. He visited the humblest recesses of poverty and sickness. He was not unmindful that bodily sickness renders the mind more impressible with moral and religious truths, and embraced opportunities, in the course of his medical practice, of exercising mental charities to afflicted minds, as well as of employing

---

HARTFORD, the second town, as to size, in the state of Connecticut, lies on the bank of Connecticut river, fifty miles above its mouth. It is in the centre of a pleasant and fertile section of the country. The houses are built chiefly on one street, parallel with the river. The intersecting streets cross it at right angles. The public edifices are, a state house, two Congregational churches, one Episcopalian, and others for the administration of justice. The houses are generally of brick, three stories, and well built. Their whole number may be about seven hundred. The population of Hartford in 1810 was 3.995. It is understood to have considerably increased. Besides its local advantages, the town has benefited by the meeting of the legislature of the state in it. It has been rendered more memorable, by the convention of delegates from the legislatures of Massachusetts, Connecticut, and Rhode-Island, in the year 1814; whose principal views were to concert opposition to the administration of the federal government, in the prosecution of the late war, &c. Hartford has many advantages. It has an extensive and fertile country lying about it. It cherishes a number of manufacturing establishments, supports several distilleries, and has a good communication with the sea. (E. H. CUMMINS, A. M.)

his knowledge of the healing art to the restoration of bodily health.

He was industrious in acquiring all collateral branches of knowledge, and lived in personal intimacy with the learned men of his age. Dr Law, Dr Butler, Dr Warburton, afterwards Bishops of Carlisle, Durham, and Gloucester, and Dr Jortin, were his intimate friends. He was much attached to Dr Hoadley, Bishop of Winchester, whose opinions on religion and politics seem to have been very similar to his own. Dr Hales, and Dr Smith, master of Trinity College in Cambridge, with other members of the Royal Society, were his companions in the sciences of optics, and other branches of natural philosophy. Mr Hawkins Browne, the author of an elegant Latin poem, *De Animi Immortalitate*, and Dr Young, the moral poet, stood high in his esteem. Dr Byrom, the inventor of a scientific short-hand writing, was much respected by him for useful and accurate judgment in philology. Mr Hooke, the Roman historian and disciple of the Newtonian chronology, was amongst his literary intimates. The celebrated poet Pope was likewise admired by him as a man of genius, and a true poet; yet he regarded the celebrated Essay on Man as tending to insinuate, that the divine revelation of the Christian religion was superfluous, in a case where human philosophy was adequate. He suspected the secret influence of Lord Bolingbroke, as guiding the poetical pen of his unsuspecting friend, to deck out in borrowed plumes the plagiarisms of modern ethics from Christian doctrines. From his earliest youth he was devoted to the sciences, particularly to logic and mathematics, which last he studied under the celebrated Professor Saunderson. He published, 1. *A View of the present Evidence for and against Stevens's Medicines as a solvent for the Stone*, London 1739, 204 pages 8vo. dedicated to the President and Fellows of the Royal College, London. His own case is the 123d in the book; yet he is said, after all, to have died of the stone, after having taken above two hundred pounds weight of soap; and it must be acknowledged, though with regret, that that celebrated medicine has no power of dissolving stones in the kidneys or bladder. 2. Dr Hartley is said to have written in defence of inoculation against Dr Warren of St Edmund's Bury; and some letters of his are to be met with in the *Phil Trans.* 3. But his most celebrated work is entitled, *Observations on Man, his Frame, his Duty, and his Expectations*, in two parts; part the first, containing observations on the frame of the human body and mind, and on their mutual connections and influences; part the second, containing observations on the duty and expectations of mankind; London, 1749. The author gives the following account of the origin and progress of the work. "About eighteen years ago, I was informed that the Rev. Mr Gay, then living, asserted the possibility of deducing all our intellectual pleasures and pains from association. This put me upon considering the power of association. Mr Gay published his sentiments on this matter, about the same time, in a dissertation on the fundamental Principle of Virtue, prefixed to Mr Archdeacon Law's translation of Archbishop King's *Origin of Evil.* From inquiring into the power of association, I was led to examine both its consequences, in respect of morality and religion, and its physical cause. By degrees, many disquisitions, foreign to the doctrine of association, or at least not immediately connected with it, intermixed themselves. I have here put together all my separate papers on these subjects, digesting them in such order as they seemed naturally to suggest, and adding such things as were necessary to make the whole appear more complete and systematical." The author, aware that he had thus laid himself open to the charge of having first adopted a theory, and afterwards accommodated his observations in subserviency to it, adds, that "he did not first form a system, and then suit the facts to it; but was carried on by a train of thoughts from one thing to another, frequently without any express design, or even any previous suspicion of the consequences that might arise; and that this was most remarkably the case in respect of the doctrine of *Necessity;* for I was not at all aware, that it followed from that of association, for several years after I had begun my inquiries; nor did I admit it at last without the greatest reluctance."

In regard to the doctrine of necessity, justice to the author requires that his note of explanation should be here given, viz. "that he no where denies practical free will, or that voluntary power over our affections and actions, by which we deliberate, suspend, and choose, and which makes an essential part of our ideas of virtue and vice, reward and punishment." To the doctrine of associations he has added *vibrations*, and endeavoured to establish a connection between these, and to shew the general use of these in explaining the nature of sensations. In the introductory remarks to the second part of the work, "*On the Duty and Expectations of Man*," he says, that "the contemplation of our frame and constitution appeared to him to have a peculiar tendency to lessen the difficulties attending natural and revealed religion, and to improve their evidences, as well as to concur with them in their determination of man's duty and expectations; with which view he drew up the foregoing observations on the frame and connexion of the body and mind: And in prosecution of the same design, he goes on in this part, from this foundation, and upon the other phenomena of nature, to deduce the truths of natural religion; laying down all these as a new foundation whereon to build the evidences for revealed religion, to inquire into the rule of life resulting from the frame of our natures, the dictates of natural religion, and the precepts of Scripture. And, lastly, to inquire into the genuine doctrines of natural and revealed religion, thus illustrated, concerning the expectations of mankind here and hereafter."

The intentions of the author seem to have been upright and pious; and considerable ingenuity, as well as acquaintance with the human frame, are displayed throughout the work. Yet few, it is believed, will be found to assert that his system throws any light on the mysterious union of matter and mind, or that his *reduction* of all the operations of the human mind to association of ideas, has tended in any degree to simplify the subject. "The philosophy of mind (observes Professor Stuart) has its alchemists; men, whose studies are directed to the pursuit of one single principle, into which the whole science may be resolved; and they flatter themselves with the hope of discovering the grand secret by which the pure gold of truth may be produced at pleasure. Of such metaphysical alchemists, Hartley is clearly entitled to the first place. But all the generalizations of his system are verbal only, and it succeeds in bringing all our mental operations under the head of associations, only by using the term in such an unprecedented latitude, as to make it comprehend all sorts of mental operations, and every kind of connection of ideas. Every thing, according to Hartley, of which we are conscious, excepting only our sensations, may be called *ideas;* and every kind of relation between them he terms an association, so that the connection betwixt twice two and four, is merely an association of ideas, and that all mathematical relations are of the same denomination. This, it is evident, is not a discovery in philosophy, but an innovation in language." (*Philosoph. Essays.*) It is said that he did not expect that his work would meet with any general or immediate reception in the philosophical world, or even that it would be much read or understood; but that at some distant period it would become the adopted system of future philosophers. There seems no probability of this expectation being realized. The prevailing systems of Reid, Stewart, &c. the inductive philosophy of mind, seems to bid much fairer for general adoption. Although Hartley cannot be recommended as a guide, either in philosophy or in religion, his private and personal character seems to have been amiable and exemplary. His thoughts were not immersed in worldly pursuits or contentions, and therefore his life was not eventful or turbulent, but placid and undisturbed by passion or violent ambition. From his earliest youth, his mental ambition was pre-occupied by the pursuits of science. His hours of amusement were likewise bestowed upon objects of taste and sentiment. Music, poetry, and history, were his favourite recreations. His natural temper was cheerful and social. He was addicted to no vice in any part of his life. The virtuous principles which are instilled in his works, were exemplified in his conduct. His person was of the middle size, and well proportioned; his complexion fair, his features regular and handsome. His countenance open, ingenuous, and animated. He was peculiarly neat in his person and attire. He was an early riser, and punctual in the employments of the day; methodical in the disposition of his library, papers, and writings, as the companions of his thoughts, but without any pedantry, either in these habits, or in any other part of his character. His behaviour was polite, easy, and graceful, flowing from benevolence of heart. His whole character was eminently marked by simplicity of manners, and uprightness of conduct. The dispositions of his heart shine very evidently through his works, and the conclusion of the work on Man, in which he addresses various classes of the community, and exposes prevailing vices, does much honour to his moral and religious character, and evince an affectionate concern for the best interests of his country, and of mankind. He died at Bath on the 28th of August, 1757, at the age of fifty-two years. He was twice married, and left issue by both marriages, two sons, and a daughter. His eldest son got a travelling fellowship, and his younger son was entered at Oxford in Michaelmas term, 1757. *See a Sketch of the Life and Character of Dr Hartley, prefixed to Notes and Additions to the work on Man.* By Herman A. Pistorius, rector of Poseritz in the island of Rugen, London, 1791; and Dodsley's *Ann. Register*, vol. xviii.

HARTZ, or Harz, a tract of mountainous country, situated in the kingdom of Hanover. It is about 70 miles long, and 20 broad. The forests of the Hartz have about one-third of hard wood, and two-thirds of soft wood. An insect belonging to the order Coleoptera, nearly allied to the *Dermestes typographus*, has lately committed great ravages in these forests. It infests fir trees, and in one tree 80,000 larvæ have been found. The principal minerals are lead, copper, silver, zinc, iron, green vitriol, blue vitriol, white vitriol, and sulphur. The silver mines, which are said to have been discovered in the year 968, were the first that were opened in Europe. The annual product of the lead, silver, and copper mines, is stated at 157.994 dollars.

The Editor is indebted to Professor Jameson for the following account of the mineralogy of the Hartz mountains.

This interesting tract of country is composed of primitive transition, flœtz, and alluvial rocks; but hitherto no volcanic substances have been met with in it.

A. *Primitive Rocks.*

These are granite, primitive greenstone, horn-rock, quartz-rock, primitive flinty slate, primitive clay slate, and primitive limestone.

1. *Granite.* This rock is supposed to form the central part of the Hartz, and consequently to support all the other mineral strata of this part of Germany. It is occasionally traversed by veins of quartz, schorl, and hornstone. At its line of junction with the superincumbent strata, intermixtures of the rocks are to be observed, and even veins of the granite shoot from the massive rock into the superincumbent ones. These facts are differently explained by the Neptunian and Plutonian speculators. The Neptunists consider them as illustrative of the *cotemporaneous formation* of the two rocks; while the Plutonists view them as irrefragible proofs of the granite having been projected in a fluid form from the interior of the earth amongst *previously existing strata.*
2. *Primitive greenstone.* This rock rests immediately on the granite, and sometimes beds of it occur in the clay-slate. Like the granite, it is magnetical, although it contains no disseminated magnetic iron-stone or magnetical pyrites.
3. *Horn-rock*, (Horn-fels.) Hitherto mineralogists have not attended to this rock. It is an intimate mixture of splintery quartz and compact felspar, in which sometimes the one, sometimes the other, mineral predominates. It is occasionally coloured black with schorl. It occurs resting upon granite, and frequently intermixed with that rock at the line of junction.
4. *Quartz-rock.* It is either splintery, or composed of granular concretions. It rests either upon the granite, or occurs in beds alternating with greenstone or horn-rock.
5. *Primitive flinty slate.* This rock occurs but sparingly in the Hartz, and is generally disposed in beds, alternating with horn-rock and clay-slate.
6. *Primitive clay-slate.* This rock forms beds in flinty-slate, primitive limestone, and green-stone.

*Metalliferous venigenous formations in primitive clay-slate.*

The following principal formations may be distinguished.

a. The veins of this formation contain principally galena or lead glance, native arsenic, red silver ore, with much calcareous spar, and a small portion of quartz.
b. This formation is almost entirely composed of galena or lead glance, with a very small portion of native arsenic, red silver ore, grey copper ore, and blende.
c. In this formation, like the preceding, galena is the predominating ore, and is associated with a small quantity of grey copper ore, iron pyrites, copper pyrites, red iron stone, brown iron ochre, and red silver ore.

7. *Primitive limestone.* It occurs but seldom, and in beds, in clay-slate.

B. *Transition Rocks.*

The following rocks of this class are met with in the Hartz, viz. limestone, greywacke, clay slate, whet slate, alum slate, transition flinty slate, transition trap, and transition porphyry.

1. *Limestone.* It occurs in beds, often of considerable thickness, in greywacke, and transition clay slate.
2. *Greywacke.* Greywacke and clay slate are by far the most abundant rocks in the Hartz. It sometimes contains glance coal, (*blind coal,*) and mineral pitch; and

occasionally petrifactions of species of the genera hysteriolites, and trochites.

3. *Clay-slate.* This rock is distinctly stratified, and sometimes occurs in elliptical and globular concretions, which have a concentric lamellar structure. It alternates with greywacke, and both rest on the primitive rocks already described.

Both greywacke and clay slate contain very considerable metalliferous formations. The following are the principal ones.

*a.* A very thick bed of copper pyrites, iron pyrites, galena or lead glance, and brown blende, with compact heavy spar, and a very small quantity of quartz, and calcareous spar.

*b.* Veins of galena or lead glance, of which the following formations have been ascertained.

α. Galena, associated with much calcareous spar, and splintery quartz, and small portions of iron pyrites, sparry iron stone, grey copper ore, and brown spar.

β. Galena, associated with sparry iron stone, calcareous spar, heavy spar, and quartz ; with a minute portion of grey copper ore, brown blende, iron pyrites, and copper pyrites.

γ. Galena, with splintery quartz, and a smaller portion of calcareous spar, sparry iron stone, iron pyrites, and copper pyrites. In the upper parts of the veins, the calcareous spar is sometimes dissolved and carried away. The galena, or lead glance, is converted into white, black, and earthy lead ores ; by the decomposition of the copper and iron pyrites, there are formed varieties of ochry brown iron stone, malachite, azure copper ore, and copper green, and by the decomposition of the sparry iron stone, compact and fibrous brown iron stones, and ores of manganese.

δ. Galena, with much brown blende, splintery quartz, and calcareous spar; and occasionally small portions of copper and iron pyrites.

ε. Galena, with amethyst, large foliated calcareous spar, copper pyrites, and brown blende.

*c.* Veins of copper ore, which are distributed in the following formations.

α. The principal vein-stone, of the veins of this formation is quartz, which occurs in such quantity as occasionally to fill up the veins from side to side. It is in granular concretions, which are so loosely aggregated, that they can be separated by the mere pressure of the finger ; hence in mines in this formation the quartz is dug out by shovels. This condition of the quartz in these veins shews us the possibility of sandstone, and even of sand, being in many cases original chemical formations, and not mechanical deposites. The ores associated with the quartz are copper pyrites, malachite, copper green, copper black, tile ore, and brown iron stone. There sometimes occur, embedded in the loose sandy quartz, blocks of compact quartz, also portions of heavy spar, and small strings of brown spar, and red iron stone ; and rarely fluor spar.

β. This formation consists of azure copper ore, and copper-green, with much fluor spar, and sometimes small portions of brown spar, and red ironstone.

γ. Copper pyrites, and splintery quartz, with small portions of calcareous spar, iron pyrites, and galena or lead glance, are minerals of this formation.

*d.* Veins of iron-stone, of which the following formations are known to the miners.

α. Red hematite, and heavy spar.

β. Compact red iron-stone, with much calcareous spar.

γ. Compact red iron-stone, with much quartz, and a small portion of iron flint.

δ. Compact, fibrous, scaly, and ochry red iron-stone, with specular iron ore or iron glance, and quartz, and calcareous spar.

ψ. Sparry iron-stone in the lower part of the veins, but brown iron-stone in the upper parts.

*e.* Veins of manganese occur but rarely ; and of this metal the only formation in the Hartz is that in which compact grey manganese ore is associated with heavy spar.

4. *Whet slate.* This mineral occurs in thin beds in the clay slate.

5. *Alum slate.* It occurs in beds in clay slate.

6. *Transition flinty slate.* It occurs in beds in greywacke and clay slate. It passes into clay slate ; and in the mountains of the Hartz we find all the intermediate varieties between perfect flinty slate, and well characterised clay slate. It is worthy of remark, that this mineral, which, according to the Huttonian view, must have been in a state of fusion, occurs inclosed in clay slate, and exhibiting the gradation we have just mentioned.

7. *Transition trap.* The trap rocks, which are greenstone, and amygdaloid, alternate in beds with greywacke and greywacke slate.

8. *Transition porphyry.* The transition porphyries have a basis either of clay-stone, felspar, or horn-stone, and occur in beds in greywacke, or in masses resting upon it.

### C. *Flœtz Rocks.*

Flœtz rocks surround the Hartz on every side, and are spread from thence over the hilly parts of Lower Saxony. The following are the flœtz rocks met with in the Hartz : Old red sand-stone, clay porphyry, alpine lime-stone, older gypsum, variegated sand-stone, newer gypsum, and third flœtz sand-stone.

1. *Old red sand-stone, or the first flœtz sand-stone.* This well known rock, the *dunstone* of English mineralogists, occurs in considerable abundance, and in this country contains beds of coal.

2. *Clay-stone porphyry.* This rock occurs in beds which alternate with the red sand-stone. The beds vary in thickness from a few inches to many fathoms. It passes into the bounding sandstone, a fact illustrative of the cotemporaneous formation of the two rocks.*

3. *Alpine lime-stone, or first flœtz lime-stone.* This limestone occurs in considerable abundance, and generally rests on the red sand-stone.

4. *Older gypsum, or first flœtz gypsum formation.* This formation, which is principally composed of foliated granular gypsum, and compact gypsum, also contains selenite, rounded cotemporaneous portions of radiated gypsum, stinkstone, and sometimes fibrous gypsum. It rests on the preceding formation.

5. *Variegated, or second flœtz sand-stone.* This formation, which is probably identical with the *red ground* of English mineralogists, rests upon the older gypsum.

* It may be noticed, that German mineralogists mention the occurrence of porphyry and trap rocks in red sand-stone as a new discovery, although both these facts were stated so early as the year 1800, by Professor Jameson, in his *Mineralogical Travels,* a work known to continental writers by the translation of it which appeared in Germany many years ago.

6. *Newer gypsum, or second flœtz gypsum formation.* The principal rocks in this formation are foliated granular, fibrous, and radiated gypsum. It rests on the variegated sand-stone, and sometimes even alternates with it.
7. *Third flœtz sand-stone.* This sandstone has generally a grey or white colour, and contains subordinate beds of slate clay, indurated marl, and coal. It appears to rest upon the newer gypsum and the variegated sand-stone.

D. *Alluvial Rocks.*

The rocks of this class are calc-tuff, loam, clay, brown coal, bog iron ore, peat, and rolled masses, of different kinds.

The following works may be consulted, as affording accurate and extensive details in regard to the natural history of the Hartz.

See the article Brocken.

HARVEY, William, M. D. the celebrated discoverer of the circulation of the blood, was born at Folkstone in Kent, on the 1st of April 1578, was educated at the school of Canterbury, and sent to Cambridge in 1593, where he studied six years as gentleman commoner of Caius College. His medical studies were prosecuted at the university of Padua, where the most eminent of his instructors was Fabricius ab Aquapendente. This anatomist explained to him the structure of the valves of the veins; a subject which he had greatly improved, and which afterwards led Harvey to views unparalleled by any in physiology for their beauty and profundity. At Padua he took the degree of M. D. and returned to England in his 24th year. At 30 he was elected Fellow of the Royal College of Physicians of London; and in about a year after succeeded Dr Wilkinson as physician to Bartholomew's hospital. On the 4th of August 1655, he delivered, by appointment of the College of Physicians, the Anatomical and Surgical Lecture of Lumley and Caldwell; and there is reason to believe, that on this occasion he gave a modest intimation of his great discoveries, as he left a manuscript, *de Anatomia Universa*, dated about this time, which contains the outlines of his doctrines. Twelve years elapsed before he published them to the world. His fame, in the mean time, gained ground, and the estimation in which he was held by his professional brethren gave it solidity, as well as brilliancy.

It was in 1628 that he published his *Exercitatio Anatomica de Cordis et Sanguinis motu*, at Frankfort, a centre from which it was most readily diffused through Europe, by means of the great book fairs which were annually held in that city. In no point of view can this work be too highly praised as a specimen of the most ingenious and solid speculation, and of striking experimental inquiries, arranged in luminous order, and accompanied with apposite illustrations. It still continues unrivalled for importance as an original publication. An account of the great doctrines which it establishes is given in our article Anatomy (*History of*,) to which we beg leave to refer.

But illustrious as the merit of Harvey was, and respectably as it was supported by the cordial admiration of his colleagues, his opinions were represented by a herd of opponents as precipitate innovations; and the inference drawn by the confiding multitude was, that the author of them could not be a safe medical practitioner. His practice as a physician actually fell off, furnishing a striking proof of the precarious and humbling conditions of a medical reputation. The bigotted abettors of old established systems, after injuring his name by whispers and innuendoes, attacked him at last by controversial writings, and thus put it in his power to vindicate the truths which he had discovered, and refute the Galenian errors which had maintained their ground for ages.

Dr Primrose of Oxford was his first opponent. He maintained that the blood was carried to the different parts of the body, not by the impulse of the heart, but by the power which all the living organs have to attract the substances fitted for their nourishment. Four years after this, he was attacked by Æmylius Parisanus, a physician of Venice, with great pomp of words, in a barbarous and obscure style of eloquence, in which he supported a strange medley of ancient opinions and peculiar original dogmata. Dr Harvey was saved the irksome task of replying to a tortuous and confused tissue of unmeaning words, by the zeal of his liberal admirer and genuine friend Sir George Ent, a physician of the highest reputation, who, in an *Apology for the Circulation of the Blood*, replete with learned and acute argument, and enlivened with eloquence and wit, completely exposed the futilities of that author.

In a few years after this he met with a more able and liberal minded opponent in Riolan of Paris, who had entertained a fanciful doctrine of his own upon the motion of the blood, which could not stand if Harvey's views were established. In answer to Riolan, Harvey wrote two treatises called *Exercitationes*. Every modern anatomist who looks back to these disputes, smiles not only at the obstinacy with which the true doctrine of the circulation was resisted, but at the gross ignorance betrayed by its opponents, in particulars of anatomical structure which are now familiar to the youngest tiro in the science. Riolan soberly maintained, that in the adult subject the left auricle of the heart was a solid mass, possessing no cavity capable of containing blood.

Dr Plemp, professor at Louvaine, was another adversary; but, finding that the experiments with which he intended to assail the doctrines of Harvey contributed powerfully to their support, he with manly candour ranked himself among his converts.

Harvey, in his first publication, did not acknowledge any regular continuation or anastomosis betwixt the small arteries and the veins, furnishing a tubular passage for the transmission of the blood, but believed that this fluid was first diffused by the terminations of the arteries among the interstices in the texture of the different organs, and was from these absorbed by the veins; and it was not without apparent reluctance that he was afterwards induced in this particular to admit the doctrine which is now universally established.

After the great discovery of Harvey was placed beyond the reach of controversy, attempts were made to detract from his merit, by showing that it was not original. Obscure passages and accidental expressions in the writings of ancient and modern authors were distorted by miserable envy, for the purpose of proving that Harvey, now acquitted of heresy, was chargeable with plagiarism. A singular circumstance occurred to give a temporary triumph to calumny. Harvey, having maintained some degree of intimacy with the Venetian ambassador at the court of London, who had heard and admired his lectures, gave him a physiological manuscript just before his departure, which the ambassador presented to Paulus Sarpius, a learned monk of his own country. After the death of this religious person, when his manuscripts were explored, a story was circulated, that the discovery of the circulation belonged to Paulus, who had communicated it either to Fabricius, or to Harvey. This unfavourable impression was easily credited, and a considerable time was required before it could be effaced.

Harvey, however, was not one of those ill-fated men of genius, who are denied all due honour till the enjoyment of it is put out of their power by death. He was caressed at court, and warmly esteemed by his scientific brethren. By what means, or at what period he was introduced to royal notice, we are not informed: but a letter from James I. of England was found among his papers, dated 1623, *i. e.* 15 years after he had connected himself with the London College, from which it appears that he had been for some time extraordinary physician to the king, and had been actively employed about the royal person. Seven years after this, in the reign of Charles I. he was promoted to the office of physician in ordinary. He was also employed to accompany the young Duke of Lennox in his continental travels.

During the civil wars, Harvey accompanied the king in his different military movements; and, after the battle of Edgehill, retired with the royal family to Oxford. In three years after this, he was appointed warden of Merton college, instead of Nathaniel Brent, who had revolted to the Presbyterian cause.

The circulation of the blood was not the only subject in which Harvey was eminent. He also made important discoveries on the subject of generation; and, at the age of 73, at the pressing request of Sir George Ent, published his work, entitled *Exercitationes de Generatione Animalium*, which contained many experiments on incubation, and the reproductive functions of viviparous animals, ingeniously contrived, and executed with much labour. One of his favourite conclusions was, that impregnation is not accomplished by the contact of the semen of the male with the embryo in the body of the female, but by a pecular stimulus communicated by it to the vagina, and by sympathy to the other female organs, and which he compared to contagion for the peculiarity of its effects;—a conclusion which he considered as supported by this fact, that a single impregnation of a female fowl was sufficient to impart a prolific quality to *ova* not yet formed.

Harvey dissected the body of Thomas Parr, so celebrated for longevity, having lived to the age of 153, and his account of the appearances which he found is delivered in his own words in the editions of his works.

Several letters written by him to men of science are also preserved and published, all of which breathe the same chaste philosophical spirit; and the latest of them shew that he retained, in extreme old age, the same admirable vivacity of intellect for which he was distinguished through life. His *Anatomia Universalis*, and some other writings not intended for publication, are preserved in manuscript in the British musuem. Some of his manuscripts, however, and most particularly those containing his extended views and experiments on generation, were, to the great detriment of science, destroyed by the licentiousness of the Parliamentary troops, when they occupied his house in London.

When Charles I. fled from Oxford, Harvey went to London, where he practised but little as a physician, spending a great part of his time in a rural retreat at Lambeth.

Having now attained to the summit of professional eminence, he received, in 1652, a splendid testimony of the esteem entertained for him by the College of Physicians. A bust of him was executed by their orders, and placed in their hall, accompanied by a complimentary inscription. He, in his turn, gave a proof of his affection for that learned body, by presenting them with a hall, and his excellent library.

In two years after, when Dr Prujean resigned the situation of president of the college, Harvey was chosen his successor; but, on account of his age and infirmities, he delicately declined that honourable charge. He continued till a very late period of his life to officiate as a lecturer. He attended the meetings of the college when important business was agitated; and, in the year 1656, he bequeathed to them his patrimonial property. Loaded with various increasing infirmities, he died on the 3d of June of the following year, aged 79, and was buried at Hampstead, where a monument, with a figure and suitable epitaph, is erected to his memory.

The College of Physicians, in 1766, published a beautiful edition of his works in one large quarto volume, to which is prefixed an account of his life by Dr Lawrence. Harvey wrote with great perspicuity, and a flowing eloquence. His works are not in the slightest degree tainted with a spirit of hostility. His controversial antagonists, even those who wrote with petulance and asperity, are treated by him in temperate and civil language. His candour, cheerfulness, and goodness of heart, were conspicuous in his whole life, as well as in his writings, and exhibit a worthy pattern for future imitation. (*H. D.*)

HARWICH is a town of England, in the county of Essex. It is situated at the north-east extremity of the county, on a point of land bounded on the east by the sea, and on the north by the estuaries of the Stour and the Orwell. The town consists of three principal streets, with various lanes branching off in different directions. The chief buildings are the chapel, built by the Earl of Norfolk about the beginning of the 13th century; the town-hall, rebuilt about 53 years ago; the school-house, and the custom-house. Its market place is inclosed, and is neat and clean. The town is walled in, and the streets are paved with a kind of clay from a petrifying spring in the neighbourhood, which makes it as hard as stone.

The inhabitants of Harwich are principally employed in ship-building and other maritime occupations. Several third rates and other large vessels have been built here. The harbour, which is independent of the bay, is spacious, deep, safe, and convenient; and a light-house has lately been erected on a hill below the town for guiding vessels into it.

The North Sea fishery gives employment to about 3000 tons of shipping, and 500 sailors belonging to this port. The people too receive much support from the Dutch packet boats, which, in time of peace, carry on a great intercourse between Harwich and the continental ports.

During the bathing season, Harwich is frequented by much company, who find here tolerably good accommodation. Bathing machines have been for some time introduced; and there are two hot and two cold salt water baths, with a steam or vapour bath, and a large bathing place, with a machine for throwing the hot or cold water on any part of the body. The buildings, which have commodious dressing rooms, stand in a large reservoir, containing many hundred tons of sea water, which is renewed every tide, so that the baths are continually supplied with fresh sea water by a contrivance on the principle of a natural syphon.

On the opposite side of the bay in Suffolk stands Landguard fort, which is built on a point of land united to Walton Colness, but so encircled by the sea at high water as to become an island nearly a mile from the shore. It completely commands the entrance to the harbour of Harwich, and was erected for this purpose in the reign of James I.

Harwich was made a burgh in the reign of Edward II.

It is governed by a mayor, 8 aldermen, 24 burgesses, a recorder, &c. and sends 2 members to parliament.

The following is the population, &c. of the burgh of Harwich for 1811.

| | |
|---|---|
| Number of inhabited houses | 564 |
| Do. of families | 910 |
| Do. employed in agriculture | 72 |
| Do. in trade and manufactures | 178 |
| Males | 1519 |
| Females | 2213 |
| Total population in 1811 | 3732 |

See Morant's *History, &c. of Essex*; Dale's *History of Harwich and Dover Court*; and the *Beauties of England and Wales*, vol. v. p. 330. For an account of Harwich Cliff, see ESSEX, vol ix. p. 206, col. 2.

HASSELQUIST, FREDERICK, a celebrated Swedish botanist, was born at Toernvalla in East Gothland, on the 3d Jan. 1722, old style. Having been left an orphan at an early age, he was for some time supported by his maternal uncle; but upon the death of this his only friend, he was obliged to support himself by teaching, even for some time after he entered the university of Upsal in 1741. In 1746, he procured a royal stipend or scholarship, and such was his progress in botanical acquirements, that he became a favourite pupil of Linnæus; and was inspired with such an ardour to examine the botany of distant countries, that though affected with a pulmonary complaint, he resolved to examine the natural history of Palestine. In 1749, he read lectures on botany in Stockholm; and having received the offer from the Levant Company of a free passage to Smyrna, he set sail on the 7th August, and arrived in that city on the 27th of Nov. 1747. During the winter, he made an excursion to Magnesia, and on the 13th May he arrived at Alexandria, and afterwards visited Rosetta and Grand Cairo. In March 1751, he proceeded to Damietta, from which he sailed to Jaffa, where he began his examination of the natural history of Palestine. On the 23d May he set sail for Cyprus, and after visiting Rhodes and Stanchio, he returned to Smyrna in the end of July. His laborious exertions had now begun to impair his strength, and though he tried a milk diet, and a winter's repose at Smyrna, yet his health gradually declined, and he died on the 9th February 1752, in the 31st year of his age.

During his travels and illness, Hasselquist had unfortunately contracted a debt of about 350*l.* sterling, and upon his death his collections and MSS. were seized by his creditors at Smyrna. As soon as the Queen of Sweden was informed of this event, she redeemed that valuable deposit, and put it under the care of Linnæus. The MSS. papers of Hasselquist were published in 1757 in Swedish, under the title of *Iter Palestinum*, in one vol. 8vo. with a biographical preface by Linnæus, and his correspondence with the author. His work has been translated into several languages, and appeared in English in London in 1766. Hasselquist is also the author of several memoirs in the Transactions of the Academies of Upsal and Stockholm, from 1750 to 1752. See the preface to his *Iter Palestinum*; Haller's *Bibliotheque Botanique*; and Rees's *Cyclopædia*.

HASTINGS, is a burgh and market town of England, in the county of Sussex. It is situated near the eastern extremity of the county, in a valley that forms a beautiful amphitheatre, sloping on the south to the sea, and flanked on the east and west by lofty hills. The town consists of two parallel streets, the High Street and Fish Street, running north and south, and separated by a rivulet called the Bourne, which supplies nearly the whole town with water, and runs into the sea. The town is well paved, and contains many handsome houses. The principal public buildings, are the two churches of All Saints and St Clement's, the town-hall and market-place, and a custom-house, with an establishment of 12 riding officers. The two churches are very ancient buildings. St Clement's is large and lofty. The town-hall was built in 1700, and has the market-place under it. There are here two excellent free schools, founded for the education of 130 scholars; and also a barrack for foot soldiers. The remains of an ancient castle are still visible on a high rocky cliff to the west of the town. The ruins resemble in form two sides of an oblique spherical triangle; having the angles rounded off. The base or south side towards the sea completes the triangle, and is formed by a perpendicular crag about 400 feet long. The east side is a plain wall about 300 feet long, and the north-west side is about 400 feet, the whole area being about 1⅕th acre. The walls are about eight feet thick. A little to the west of the crag, are the remains of a priory of Black Canons.

Hastings is one of the cinque ports. It had formerly a good harbour and a considerable trade; but as the harbour is choked up with sand, it now carries on merely a small coasting trade with London. Immense numbers of mackarel, herrings, soles, &c. are caught here, and forwarded by land carriage to the London market. The only way to secure ships is to draw them up on the beach, which is here called the Stade. At the west end of it is a fort mounting eleven 12-pounders. Boat building is carried on here to a considerable extent; and considerable occupation is given to the inhabitants by a lime company, which employs nine sloops of 40 tons burthen, in bringing the chalk from the Holywell pits at Beachy Head, from April to November. About 120,000 bushels of lime are annually made at the kilns, which are situated to the west of the town.

Like other towns upon the coast, Hastings draws considerable advantages from sea-bathing. Twenty bathing machines stand to the west of the town, close to a newly formed walk called the *Parade*. The beach is here admirable; and convenient warm baths have been established some time ago by subscription. At the distance of two miles from the town is a large broad stone, on which William the Conqueror dined when he landed here. It is called the "Conqueror's Table."

The following is the statistical abstract for the town in 1811:

| | |
|---|---|
| Number of inhabited houses | 665 |
| Do. of families | 789 |
| Do. employed in agriculture | 45 |
| Do. in trade and manufactures | 479 |
| Males | 1739 |
| Females | 2109 |
| Total Population in 1811 | 3848 |

East Long. 41′ 25″, North Lat. 50° 52′ 10″, according to trigonometrical observations. See the *Guide to the Watering Places* 1805; and the *Beauties of England and Wales*, vol. xiv. p. 184.

HASTINGS, BATTLE OF. See ENGLAND.

HAT, is the name of a piece of dress worn upon the head by both sexes, but principally by the men. The use of hats seems to have been first introduced among the ecclesiastics in the 12th century, and it was not till the year 1400 that they seem to have been pretty generally adopted.

As the art of making common hats does not involve the description of any curious machinery, or any very interesting processes, we shall not enter into minute details upon the subject. It will be sufficient to convey to our readers a very general idea of the method which is employed.

The materials employed in making hats, are the fur of hares and rabbits freed from the hair, together with wool and beaver. The beaver is reserved for the finest hats.

The fur is first laid upon a *hurdle* made of wood or wire, with longitudinal openings; and the operator, by means of an instrument called the *bow*, (which is a piece of elastic ash, six or seven feet long, with a catgut stretched between its two extremities, and made to vibrate by a bowstick,) makes the vibrating string strike and play upon the fur, so as to throw the fibres together, while the dust and filth descend through the chinks of the hurdle. A sieve or searce has sometimes been used for the same purpose.

After the fur is thus driven by the bow from one end of the hurdle to the other, it forms a mass called a *batt*, which is only half the quantity sufficient for a hat. The *batt* or *capade*, thus formed, is rendered compact by pressing it down with a *hardening skin*, (a piece of half tanned leather,) and the union of the fibres is increased by covering it with a cloth, and allowing the workman to press it together repeatedly with his hands. The cloth being taken off, a piece of paper, with its corners doubled in, so as to give it a triangular outline, is laid above the batt. The opposite edges of the batt are then folded over the paper, and being brought together and pressed with the hands, they form a conical cap. This cap is next laid upon another batt, ready hardened, so that the joined edges of the first batt rest upon the new batt. This new batt is folded over the other, and its edges joined by pressure as before; so that the joining of the first conical cap is opposite that of the second. This compound batt is now wrought with the hands for a considerable time upon the hurdle, being occasionally sprinkled with clear water till the hat is *basoned*, or rendered tolerably firm.

The cap is now taken to a wooden receiver, like a very flat mill-hopper, consisting of eight wooden planes, sloping gently to the centre, which contains a kettle filled with water acidulated with sulphuric acid. In this liquor the hat is occasionally dipped, and wrought by the hands, and sometimes with a roller, upon the sloping planks. The hat is thus fulled or thickened for four or five hours; knots or hard substances are picked out by the workman, and felt is added by means of a wet brush to those parts that require it. The beaver is laid on at the end of this operation, and in the case of beaver hats, the grounds of beer are added to the liquor in the kettle.

The hat is now to receive its proper shape. For this purpose the workman turns up the edge or rim to the depth of about 1½ inch, and then returns the point of the cone back again through the axis of the cap, so as to produce another inner fold of the same depth. A third fold is produced by returning the point of the cone again, and so on till the whole resembles a flat circular piece, having a number of concentric folds. In this state it is laid upon the plank, and wetted with the liquor, the workman pulls out the point with his fingers, and presses it down with his hand, turning it at the same time round on its centre upon the plank, till a flat portion, equal to the crown of the hat, is rubbed out. This flat crown is now placed upon a block, and by forcing a string, called a *commander*, down the sides of the block, he forces the parts adjacent to the crown to assume a cylindrical figure. The rim now appears like a puckered appendage round the cylindrical cone; but the proper figure is now given to it by working and rubbing it.

The hat being dried, its nap is raised or loosened with a wire brush or card, and sometimes it is previously *pounced* or rubbed with pumice, to take off the coarser parts, and afterwards rubbed over with seal skin. The hat is now tied with a pack-thread upon its block, and is then dyed, by being first boiled with logwood, and afterwards immersed in a saline solution, consisting of a mixture of green copperas and blue vitriol.

The dyed hats are now removed to the stiffening shop. Beer grounds are now applied on the inside of the crown, for the purpose of preventing the glue from coming through; and when the beer grounds are dried, glue, (gum Senegal is sometimes used,) a little thinner than that used by carpenters, is laid with a brush on the inside of the crown, and the lower surface of the brim.

The hat is now softened by exposure to steam, on the *steaming* bason, and is then brushed and ironed till it receives the proper gloss. It is then cut round at the brim by a knife fixed at the end of a guage, which rests against the crown: The brim, however, is not cut entirely through, but is torn off so as to leave an edging of beaver round the external rim of the hat. The crown being tied up in gauze paper, which is neatly ironed down, is then ready for the last opnseratio of lining and binding.

Hats are frequently made of straw, or of the chips and shavings of wood woven or plaited together, to form ribbons of narrow widths; and these are wound spirally round a block, and sewed together in a cylindrical form, so as to form the hat. The rim or border is made in a similar manner, and sewed to the hat afterwards.

The manufacture of straw hats gives employment to vast numbers of the poor inhabitants of Hertfordshire and Bedfordshire. They select the whitest and most regular straws, and cut them exactly into lengths; the straws are then whitened, by inclosing a great number of bundles in a large box, leaving a considerable space in the middle, into which a cup filled with sulphur is placed, and this being lighted, the box is shut close, and covered up with a wet blanket, to keep in the vapour of the burning sulphur, which insinuates itself through all the bundles of straw contained in the box, and renders them whiter, and of a more delicate colour. After this preparation, the straws are split lengthwise into several segments by a wire fitted to the interior capacity of the straw, and having four, six, or eight leaves, sharp on the upper edges, and projecting radially from the wires. The straws will easily split in the proper manner when the wire is forced through them. For the convenience of holding this tool, the wire is bent at right angles, about an inch below the part where the leaves project from it, and this bent part is fixed in a handle. The slips of straw are now softened in water, and plaited together by children, with great rapidity and exactness. The most simple plait is that of three straws; but this is only for very coarse articles, and the slips of the straws are very broad. Sometimes whole straws are employed, being first pinched flat by softening them, and drawing them through the fingers. The most esteemed plait is that of six straws, and is more or less valuable as it is finer or coarser; and after the plait is finished, it is passed several times between a pair of small wooden rollers, to render the ribbon flat and solid. Of these ribbons the hat is formed, by winding them, in a spiral direction, round a proper shaped wooden mould or block with a little overlap, and sewing them fast together; and when it is thus finished, the whole is passed over with a hot iron, to smooth down the seams, and the block is then taken to pieces, to withdraw it from the hat.

The Society of Arts have lately published a description of a machine for ironing down the hats upon the block. For this purpose the block is fixed upon a vertical spindle, so as to turn round horizontally; and the pressure is given by a heated steel plate, fixed in the middle of a long lever, the fulcrum of which is supported with an universal joint, at the top of an iron stem rising up from the table upon which the machine is placed. The opposite end of the lever has a handle, with which the workman presses the steel plate down upon the straw, and rubs it sidewise to smooth it down, at the same time he turns the block and hat round upon its spindle, by means of cross arms provided for that purpose, to present every part to the action of the steel. An iron box is formed just over the steel plate to receive a red hot heater, and this is kept in by a lid. It is stated as a great advantage of this machine, that the pressure of the lever being considerable, the hot steel plate can be quickly passed over the straw, and does not therefore injure the colour.

The importation of straw hats from Germany and Italy is very considerable. They have the reputation of producing the best articles of that kind at Leghorn, from whence more than 12,000 dozen have been imported in one year. Mr Corstoul, in a memoir to the Society of Arts, has shewn the practicability of producing an adequate substitute for this article in England, by plaiting the straw of rye, which he cultivated on a poor sandy soil in Norfolk, sown at the rate of two bushels per acre. He found that the produce of four square yards, when manufactured, was ten yards of Leghorn plait, of four different qualities, and weighing one ounce.

Chips or shavings of wood are also used for making hats; and some hats of this substance are woven altogether in one piece, or they are woven in wide pieces, which are afterwards made up into the figure of the hat. Sometimes the chips are only used as the fabric of the hat, and are woven in with silk, which also covers the chips, and forms the exterior surface. A patent was granted in 1808 to Mr Thomas, of London, for an ingenious machine which weaves the whole hat in this way, and of the intended figure, without any seams. PLATE CCLXXXVIII. Fig. 7. is an elevation, and Fig. 8. a section of this machine, in which A is the block or mould, upon which the hat is to be formed, and so put together in pieces as to separate for the purpose of taking off the hat. It is fixed upon a square stem B, which rises and falls into a square tube D, by the action of a pinion *a* upon a rack which is fixed to the stem. The tube D is supported upon a pivot at the lower end, and is embraced at about half its length by a collar E, in the frame or pedestal EFF, which sustains the whole machine, but permits it to turn round upon the pivot, that the workman who sits with the machine before him, may bring every part of the block towards him. He can turn it round by applying his foot to the circular board or wheel *e e*, which projects from the axle or tube D at the lower end. The top of the tube D carries a cylindrical wooden box G, large enough to contain the block A without touching it; and upon the upper edge of this cylinder is fixed a projecting flaunch or circular plate. Around the circumference of the plate, a circle is described, and a row of holes pierced at equal distances, so as to divide the circle into 72 parts, and each hole receives a wire *h*. Immediately within the row another circle is made, and divided into the same number of holes; but the wires *i* which pass through these latter holes are interspaced between the former. Each wire has an eye formed through its upper end, for the reception of a slip of chip, marked *k l*, of which there will be 144 in number, radiating from the centre of the block, to which they are all made fast by a plug; and after passing through the eyes of the wires *k* and *l*, the slips hang down, and have small leaden plumbets *m*, *m* appended to them, to stretch them straight.

The lower ends of the wires *i* are all jointed to a circular ring of wood *o o*, which fits upon the external surface of the cylindrical box G, and slides freely up and down thereupon; in like manner the interior wires *k* are jointed at the lower ends to a similar ring *i i*, which is connected with the former ring *o o* by two small cords, which pass over pulleys fixed in the flaunch *g*, and consequently when either the rings *i* or *o* are pulled down the other must be raisde up, and *vice versa*. To draw down the lower ring *o*, it has two wires *p*, *p* (Fig. 7.) joined to it at the opposite sides, and these descend to the treadle *r*, upon which the workman places his foot; and the action of this pressure is to divide the whole number of shreds of chip into two sets *k* and *l*, one of which is depressed, and the other elevated. The weaving is performed by passing a knitting needle filled with silk in the space or angle between *k* and *l*, until it has made a whole circuit round the block or crown of the hat; then, relieving the pressure upon the treadle *r*, the weights *m* cause the wire *h* and ring *i* to descend, and the other set of wires *i*, and their ring *o*, to ascend, by which means the situation of the chips *k* and *l* become reversed, *l* being the uppermost, and *k* the lowest. In this situation the needle is again passed round in the opening between them. This done, the treadle *r* is depressed to restore them to the position of the Figure, and the needle is again passed; and thus the operation is continued until the whole is woven together; the chips radiating from the centre forming the warp, and the silk the weft, running in circular or rather spiral lines, and passing alternately over and under every chip. In some cases two needles of silk are employed, one preceding in one direction, and the other in the opposite direction, or one passing over any chip whilst the other passes under it; and in this way the whole surface of the hat is of silk, the chips being all covered. When the crown of the hat is finished in this way, the cylindrical part is done by raising up the block by its rack and pinion; and at last the block is taken to pieces to get the hat off.

HATCHING, is exclusion of the young from the eggs of animals, either by the temperature of the circumambient air, artificial heat, or the incubation of birds.

Nature has adopted some remarkable distinctions in the mode of propagating animals. Some are brought to perfection in the womb of the mother; others, originally concentrated in eggs, are discharged either in that state, where the future concourse of the male is required to excite the vital spark, or where the latent embryo will be unfolded by the simple application of heat. To the first class belongs the offspring of all quadrupeds; the second includes many of the amphibious tribes, especially toads, frogs, and newts; and the third, the whole class of birds, numerous fishes and reptiles, and most of the insect, molluscar, and vermicular tribes. Hatching and incubation have therefore different meanings, or the former, which applies to every kind of evolution of the nascent being, may be said to include the latter. Most animals that produce eggs, leave them simply to the care of nature, and certainly never recognise their offspring after birth, at least with some exceptions, of which there is a prominent example in the crocodile. But in so far as we can yet ascertain, all birds impart their natural heat to their eggs by incubation, and watch the developement and subsequent growth of their young. Some distant analogy may therefore be conceived to subsist between gestation and incubation, in the respective period necessary for each, according to the genera and species of animals. The period of gestation is generally, perhaps universally, longer in the larger viviparous tribes; and incubation is protracted, in proportion to the size of the bird. One irreconcileable difference, however, subsists, in there being no known method of accelerating the former, while exclusion of the young from the egg may be promoted, by augmenting the intensity of the temperature. We are yet unacquainted with the process undergone by the egg of the largest of the feathered race, the ostrich: some assert that its exclusion is left entirely to the effects of the sun; while others maintain that it is aided by the incubation of the female. That of the swan requires incubation during 42 days; that of the domestic hen 21; and that of the linnet 14. But we are told, that the period is somewhat abridged in the warmer climates; that the egg of the common fowl has been brought out in 13 days, by the aid of artificial heat; and that, by the diminution or interruption of the temperature, it has been retarded for six weeks. It appears, that the heat of 104° of Fahrenheit's thermometer is required to hatch the eggs of all birds, the largest and smallest, and that the surface of the skin of the mother imparts it to that extent. Thus nothing more is required for the evolution of fecundated eggs, than the simple application of any kind of heat.

These facts have been a long time established beyond controversy, whence they could not escape the notice of the ancients, as they now attract the consideration of the most unlearned observers. Instead of abiding by the ordinary course which nature has herself committed to the parent, mankind, for the sake of deriving more profit from their own contrivances, have resorted to the means of hatching birds by artificial heat. The earliest information concerning this process, is probably obtained from Aristotle in these words: "Although incubation be the common method employed by nature for bringing out eggs, it is not exclusive; for we see that in Egypt eggs will be hatched of themselves in the earth, if covered over and heated by litter." And he farther remarks, "that when heated in certain vases wherein they are deposited, they hatch of themselves." Diodorus Siculus expresses his admiration of the contrivance; and Pliny, who lived a century after Diodorus, remarks, that "eggs are excluded of themselves quite naturally, and without the aid of incubation by fowls, as in the dunghills of Egypt." Nevertheless, on comparing this with other passages of his works, it is obvious that Pliny could not have been ignorant that the application of simple heat was effectual. He and Suetonius relate, that Livia, the wife of Augustus, who had before been married to Tiberius Nero, became pregnant, and desiring, with all the ardour of a youthful female, to discover of which sex her offspring would be, took an egg, that had undergone partial incubation, and kept it warm in her bosom. When obliged to desist, it was always committed to one of her women, that the same invariable heat might be preserved. Her object was successful; and the latter biographer informs us, that "from this egg a cock was hatched with a very remarkable crest." Pliny therefore concludes, "It is probably on such principles, that a method was not long ago devised, of placing eggs in straw heated by a slow fire, a man being occupied in turning them at different intervals until their chickens were hatched." In another work of the ancients, the *Geoponica*, there is a whole chapter ascribed to Democritus, treating of "how it is possible to hatch eggs without the aid of fowls;" and the principle is analogous to the employment of dunghills. The eggs are to be placed in jars, observing to mark the date of deposition on the shell of each, on purpose to ascertain when the 20 days necessary for their exclusion shall have elapsed. Then the shell is to be broken, and the chickens supplied with food. It is unnecessary to insist farther on the practice of the ancients; but as Herodotus passes over that of the Egyptians in silence, some authors have dated its commencement between his era and the age of Aristotle, which were not remote from each other.

This branch of industry, though continued to the present day, as we shall have a future opportunity of illustrating, is not peculiar to Egypt. It was adopted at Naples in the fifteenth century, where there was a palace belonging to King Alphonso II. containing an oven that could hatch 1000 chickens. Francis I. of France, is said to have made experiments on the same subject at his chateau of Mont Trichard, in the sixteenth century; and Thevenot, at a later period, affirms that one of the Grand Dukes of Tuscany, obtained an Egyptian to superintend his proceedings; and also refers to the same process being adopted in Poland.

The art however seems to have been practised on the most extensive scale in Egypt, to which country we are constantly referred for details on the art of hatching birds by artificial heat. The Royal Academy of Sciences at Paris, indeed, esteemed this subject sufficiently interesting for particular inquiry, and from the investigations which they made, as well as from the accounts of various travellers, we have obtained the following information.

A rectangular edifice of brick or clay, called a *mamal*, is constructed, half sunk in the earth. Niebuhr describes one at Cairo, as being in a manner implanted in a hillock. It consists of two stories communicating with each other, and down the middle there is a passage, probably for the attendants. Each side of the passage is partitioned into 5, 6, or 8 chambers, or any other number, as no general rule seems to be preserved, and in these the eggs are deposited. At the outside of one angle of the building there is a furnace or fire-place, and this being filled with a mixture of cow's and camel's dung, the ordinary fuel of that country, the heat is conveyed to both stories by means of flues during 3 or 4 hours daily, at different intervals; but after ten days fire is no longer supplied, the oven being sufficiently heated. Lest the heat should be too great, ventilators are used; but those who conduct the process have no other rule, than to render the temperature equivalent to that of the baths of the country, and, if it is greater at first, they affirm, that it will occasion no injury. When the oven is converted to use, the floor of the compartments is covered with a mat, above which there is a bed of straw, and then a layer of eggs. Niebuhr says, a second tier of eggs covers the first. Mr Browne, if we rightly recollect, affirms, that the eggs are deposited in such a manner as not to touch each other. All are turned twice each day, and four times during the night. Towards the eighth or tenth day, they are examined with a lamp, and those which appear unimpregnated are rejected, and in fourteen days the whole are transferred to the upper story. At length, on the twentieth and twenty-first day, exclusion takes place; and as the chickens can subsist two days without food, their owners have sufficient time to receive them, or they are sold to others.

The number of mamals distributed throughout Egypt in the beginning of the last century was 386, according to Father Sicard; and the number of eggs hatched in each is said, by him and other travellers, to amount to 40,000, 50,000, or even 80,000 eggs, a fact almost incredible. But in the arrangements necessary to encourage and preserve such a branch of industry, a circle of several villages must bring to the mamal all the eggs belonging to that particular district. The inhabitants are liable to penalties if they dispose of them elsewhere; and the proprietor of the mamal is also limited by certain restrictions. He is entitled to select those eggs which he deems sufficient, and is responsible for a produce corresponding to only two-thirds of the number. Thus the owner of 3000 eggs receives only 2000 chickens; but as unreasonable profits would sometimes be derived from the surplus, he is entitled to redeem the chickens at a certain price from the proprietor of the oven. Dr Graves, in a paper in the *Philosophical Transactions*, says, that 200 pounds of litter are daily required for heating the mamals; and Pococke observes, that it is scarcely possible to enter them on account of the smoke.

The success of this process is supposed to result more from the nature of the climate in Egypt, where it is practised only during certain seasons, than from any particular ingenuity. Sudden alterations of weather may be destructive of the progeny; and an instance is given, where the occurrence of a shower cooled the atmosphere so much that 4000 chickens, nearly matured, perished in one oven. It is affirmed, that the inhabitants of a village called Bermé, situated on the Delta, are almost exclusively the managers of the process, which is transmitted from father to son, and preserved secret among them. At appointed times, they disperse themselves throughout Egypt, to take care of the ovens.

The modern Chinese are well acquainted with the method of hatching chickens by artificial heat. Mr Barrow mentions, that even those families practise it who have a permanent abode on water. They deposit the eggs in sand, at the bottom of wooden boxes, which are placed on iron plates kept moderately warm. Thus, while a new brood is obtained, the old birds continue laying nearly without interruption.

M. de Reaumur, an ingenious naturalist, devoted much time and attention to the subject of hatching eggs by artificial heat, which he seems to have been desirous of introducing into France under the superintendence of a Bermean. He adopted different methods of accomplishing this, which are copiously detailed in a work on the subject, that has been translated into several European languages. Two plans were principally followed; the first, which was analogous to that of the Egyptians, consisted in raising a superstructure above three bakers ovens, for containing the eggs. A small carriage on wheels, or rollers, was formed, in which were several drawers, or shelves, whereon the eggs were placed in successive rows, or strata, that is, one layer on each. The carriage could be brought at pleasure on its wheels to any part of the surface, and the state of all the eggs could be ascertained on pulling out the shelves, or drawers, in which a thermometer likewise lay, for indicating the heat. By means of this simple apparatus, Reaumur succeeded perfectly in hatching chickens; and he acquaints us, that a nun, to whom he entrusted his first experiment, in the oven of a convent, obtained 20 from 100 eggs. He conceives that a suitable oven, twelve feet square and four feet high, with a stove in the centre, could be erected at little expence, which would necessarily be heated to 104°. Instead of thermometers, the temperature may be ascertained by melting a piece of butter, as large as a walnut, with half as much tallow in a phial. When it flows like a thick syrup on inclining the phial the proper heat is obtained.

The second, though a less efficacious plan, adopted by Reaumur, consisted in burying casks of eggs in a dunghill, the warmth of which might promote exclusion. Here, however, he was opposed by uncommon difficulties; and he acknowledges that, had the former expedient been first devised, he should never have resorted to the latter. His experiments were originally made by depositing the eggs simply in the dunghill in an oblong cavity, covered by two planks. Most of them advanced favourably during eight or ten days; but after this they became putrid, disseminating an infectious effluvia, and not one produced its young. On employing casks, Reaumur suspended three flat baskets or sieves at intervals within them, containing one or two layers of eggs, along with thermometers. However, the temperature of the dunghill being subject to continual variation, occasioned great embarrassment; and the author conceives that the experiment may be more successful by resorting to several, which may possess different degrees of heat. To preserve it permanently equal is very difficult; and turning the eggs is also attended with trouble. In the course of his experiments, Reaumur found, that, though the temperature should be regularly 104°, the expanding embryo could exist at from 115° to 122°; and that an egg, during the period of total developement, loses about a fifth or sixth of its weight. He found that a humid and mephitic vapour arising from the dunghill injured the nascent young more than heat. He therefore devised a new kind of oven, heated in the same manner as the casks by a dunghill, but resembling the superstructure he had used on the baker's oven. This was a rectangular box or case, six or seven feet long, between 21 and 40 inches broad, and about 8 inches high. It was immersed in a dunghill, leaving one end open, and the eggs were placed on a carriage or tablet moved in upon rollers. By observing proper precautions, Reaumur succeeded in hatching about three-fourths of the eggs he employed.

From the brief abstract now given, a general idea may be formed of the two different methods; but M. de Reaumur's work itself must be consulted for the details. As it is not uncommon, we shall proceed to give an account of other expedients suggested or adopted by a more recent naturalist, the author of the *Ornithotrophie Artificielle*; more especially as we do not know that they have ever been alluded to in any English work.

This author employed a circular oven of earthen-ware as a model of his great plan, heated by a cylinder of boiling water passing through its centre and resting on a fire-place below. This model, which proved sufficient for practice, is 28 inches high, by 24 in diameter; and an inch thick in the sides. The top is arched; and some inches below the commencement of the arch are four holes opposite to each other, two inches in diameter, for ventilators; because in all these experiments ventilation must be strictly attended to; as also other four near the bottom, of one inch in diameter, two of which penetrate the sides of the oven horizontally, and two obliquely. All have cork stoppers. There is a door half way up the side of the oven, six or seven inches square, which may be opened to admit the hand for internal operations, with a hole and a cork stopper of an inch diameter in the middle. This oven, which, it will be observed, is of a cylindrical form, is closely luted to an earthen-ware table, two feet and a half square, and two inches thick, with a hole in the centre for receiving the column or cylinder of hot water. Below the table, and between its feet, there is a small stove, also of earthen ware, about ten inches deep and seven in diameter, which, besides a door on hinges like that of a common stove, six inches by five, has other two openings. One of these is in the centre of the top, three inches in diameter, to admit the base of the metal cylinder for water; the other is in that side opposite the door, nearly three inches in diameter, and three inches lower than the former. Its use is to carry off the smoke from a grate of live coal whereon this stove is to be placed. But one of the most essential parts, the one indeed where the chief merit of the contrivance lies, consists in the means of heating the oven by a hollow tin cylinder, three inches in diameter, let down into the hole at the top of the arch above, and resting on the stove below, which is situated on the grate. By the boiling of water contained in it, the requisite heat is obtained; and its degree is regulated by the ventilators. The cylinder must be closely luted to all the three apertures through which it passes, that is, the top and bottom of the oven, and the top of the stove; but it is necessary that about two inches should intervene between the top of the stove and the table or bottom of the oven. A moveable lid of block tin, with a hole of an inch diameter in the centre, covers the top of the cylinder, which projects a little above the oven. In practice, it is found more convenient to increase the cylinder to the diameter of four inches, and some enlargement of the stove is also advantageous. The eggs may be deposited on cards or small shelves, three or four inches broad, ranged around the interior, and separated by intervals of three or four inches high, so as to contain above 300.

Should the reader understand the preceding description, he will easily comprehend the mode of enlargement of all the parts, when real service and operations on an extensive scale are required. A circular brick building, arched above, seven feet eight inches high to the spring of the arch within, seven feet of internal diameter, and eight inches thick in the wall, is to be erected. Ventilators, as before, are in the sides; and the door is four feet high, glazed in the upper part. Ten successive tiers of shelves, a foot broad, project from the whole internal circumference, leaving an interval of seven inches between them; and as 44 or 45 eggs occupy a foot square, these shelves will contain 8000. The cylinder of water must be a foot in diameter, projecting above the building, and entering a stove below, over a furnace which is now to be sunk in the ground. It is necessary to keep a thermometer constantly immersed in it; and a hygrometer is also required to ascertain the humidity of the interior of the edifice, which is to be lined all over with lambskins, and covered externally by woollen stuffs. Moveable skylights in the roof admit fresh air into the building. The advantage of using hot water is, the equal and uniform diffusion of temperature throughout the oven, which, at the edges of the shelves, should be 106°, and will be indicated by the thermometers deposited there.

After selecting the eggs, they are to be laid on a thin bed of very dry rubbed straw, and turned three or four times daily. The ventilators are to be opened twice a-day. On the sixth day it will be seen on inspection what eggs should be removed as unproductive, and this examination ought to be repeated on the fifteenth. Towards the nineteenth day it is proper to stretch mattings over the edges of the shelves, to guard the young brood, which will appear on the twentieth or twenty-first, from falling over. The period of exclusion is sometimes accelerated or retarded; the operator should continue removing the shells, and aiding the weaker chickens to free themselves; but the remaining eggs are to be withdrawn as unproductive only on the twenty-third day.

With regard to the actual practice which the inventor of these methods followed, it appears that in two experiments on fifty eggs each, when the model was used, the first had but indifferent success, from the heat having been kept too low: but, in the second, chickens were obtained from the whole impregnated eggs, except three or four. Eight broods were attempted in the large oven, each quantity of eggs consisting at a medium of from 2000 to 3000, and the experiments were made at different seasons. At an average the product did not exceed one in six, while, in trying natural incubation at the same time, about two-thirds of the eggs were hatched. The dryness of the internal air proved injurious, and chickens of larger size were procured, by obtaining an artificial humidity from the evaporation of water in vessels.

It is generally understood, that chickens hatched in this way are not equal in strength and size to those procured by the regular process of nature; many are maimed, and it is said that monstrosities are frequent.

When the young brood has escaped, the heat of the oven may be reduced to 95° or 90°, and they may be fed, though they can subsist a day or two without meat. They may then be consigned in great numbers to the care of capons, trained on purpose. But as capons are very rare in this country, and as on the continent it was found more convenient to prosecute the process without the intervention of other animals, *artificial mothers* have been contrived. These are of different kinds, but one of the best is a low cage, of two or more stages, stuffed within, and lined with feathers: or there is another equally useful, consisting merely of two opposite shelves, near the ground, stuck over with feathers below, under which the animals may creep at pleasure. See Reaumur *Art de faire eclore et d'Elever en toute saison des Oiseaux Domestiques*; and *Ornithotrophic Artificielle ou art de faire eclore et d'Elever la Volaille par le moyen d'un chaleur Artificielle.* (c)

HAVANNAH is the principal town in the island of Cuba. It is situated on the north coast of the island, about 45 leagues from Cape Sable, and 80 coastwise from St Antonio, in a fertile and agreeable tract. It is built in a semicircular shape, the shore forming the chord, and is nearly two miles in circuit. The town is, upon the whole, regularly built, but the squares are irregular, and the streets narrow; some of the principal ones being paved with iron-wood, which is very durable. Near the middle of the town is a spacious square, enclosed by uniform buildings. The houses are disfigured with heavy balconies and wooden railings, and are by no means elegant. The town contains 11 handsome and richly ornamented churches, two hospitals, and other public buildings. The Recollects church has 12 beautiful chapels, and in the monastery are cells for 50 fathers. The church of St Clara has seven altars, adorned with plate; and the nunnery contains 100 women and servants. The church of the Augustines has 13 altars, and that of St Juan de Dios. 9. The arsenal is a very superb edifice. The harbour, which is about a league in breadth, is capable of containing all the navies of Europe; and it is so safe that they could lie without cable or anchor. There is generally a depth of six fathoms of water in the bay. This harbour is strongly fortified, both by nature and art. The entrance to it is through a very narrow channel, about 1200 yards long, and confined by rocks. The entrance is guarded by platforms and various works, mounted with artillery. The mouth of the channel is also defended by two strong forts. The fort on the east side, situated on a rock, is called the Morro. It is of a triangular form, and is fortified with bastions and 40 pieces of cannon. The other fort on the west side, and adjoining to the town, is of a square form, and is called the Punta. The other forts are El Fuerte, a square fort, mounting 22 pieces of cannon, the battery of the 12 apostles, and the shepherd's battery mounting 14 guns. As the town can only be attacked on the landside, it is strongly defended in that quarter; but the forts are commanded by several eminences, of which an enemy would readily take advantage. The Punta, the El Fuerte, and in a great measure the Morro, are commanded by the Cavannas, on a part of which the Morro is built. The north side of the eminence, on which the church of the suburb called Guadaloupe is built, flanks the Punta gate, while its south-east side commands the dock-yard. It is said that the works cover such a vast extent, that 15,000 men, who are the most that could be employed, are not sufficient to invest them. There are no fewer than 800 cannon mounted on all the works. An enemy's squadron can only anchor at the foot of the castle of St John D'Ulua. This celebrated fort contains no other water but that of the cisterns, which have lately undergone a great improvement, having been subject to split, from the discharge of artillery. The town was taken by the Buccaneers, under Captain Morgan, in 1669, and on the 13th August 1762 by the English, under Lord Albemarle and Sir George Pocock. The Morro was in this case taken by storm. It was, however, restored to Spain, at the peace of Paris in 1763.

The Havannah is the most important of the Spanish settlements in America, and is considered as the key of the West Indies. All the ships that came from the Spanish settlements, and formerly the galleons and flota, assembled at the Havannah.

There are large dock-yards at the Havannah for building ships of war. The masts, the iron work, and the cordage, are brought from Europe. The other materials are obtained in abundance in the island.

The trade of the Havannah consists in skins, tobacco, wood, sugar, dry confections, and generally of all the productions of the island of Cuba. Humboldt gives the following statement of the trade of the Havannah: Exportation in native produce eight millions of piastres, of which 31,600,000 kilogrammes (69,678,000 lb. avoirdupois), or 6,320,000 piastres in sugar (valuing the chest of sugar at 40 piastres), 525,000 kilogrammes (1,157,625 lb. avoirdupois), or 720,000 piastres in wax (the arroba at 18 piastres), 625,000 kilogrammes (1378,125 lb. avoirdupois) or 250,000 piastres in coffee (the arroba at five piastres. The exportation of sugar, which was next to nothing before 1760, amounted in 1792 to 14,600,000 kilogrammes, in 1796 to 24,000,000 of kilogrammes, and from 1799 to 1803, at an average, to 33,200,000 kilogrammes annually. In 1802 the harvest of sugar was so abundant, that the exportation rose to 40,880,000, kilogrammes (90,040,400 lb. avoirdupois); so that this branch of trade has been almost tripled in ten years. The customs of the Havannah amounted, between 1799 and 1803, at an average, to 2,047,000 piastres annually; and in 1802 they exceeded 2,400,000 piastres. The total amount of the trade is 20,000,000 piastres.

On the 19th January 1796, the city of the Havannah was honoured with the remains of the illustrious navigator Columbus. In consequence of an order contained in his will, his body was removed from the Carthusian convent of Seville, and deposited, along with the chains with which he had been loaded at Cuba, on the right of the high altar of the cathedral of St Domingo. When this island was ceded to the French, his descendants directed that the brass coffin, in which the whole was contained, should be removed to the Havannah, which was done on the 19th January 1796. The coffin was carried down to the harbour in procession, and under the fire of the forts, was put on board a brig, which conveyed them to the Havannah, where it was deposited without any monument. The city is supplied with water by the small river Lageda, which has its origin in the hills on the south-west side of the town. One of the three streams into which it divides itself runs into the sea to the east of the town, while the other two flow through the city. The population of the Havannah has been recently stated at 25,000; but Morse informs us, that an intelligent traveller has lately estimated it at 70,000. There are no fewer than 3000 cabriolets in the town. The position of the house of Don Antonio Robredo at the Havannah, according to the newly published observations of M. Ferber, is West Longitude 82° 5′ 47″, and North Latitude 23° 8′ 16″. See our article Cuba.

HAVERFORDWEST, called *Hwlffordit*, is a town of South Wales, and the capital of the county of Pembroke. It is situated on the side of a very steep hill on the banks of the river Daugleddy or Cliddy, which forms a bay for packets and vessels, and which is crossed by a good stone bridge. In the upper part of the town there are some good houses; but from the irregularity of the avenues, from the narrowness of the greater part of the streets, and from the confused manner in which the houses are piled one above another on the steep declivity of the hill, it has a very singular and unpromising appearance to a stranger. The principal public establishments are three churches, St Mary's, St Martin's and St Thomas's, a custom-house, a free school, a charity school, an alms-house, and a good quay, at which vessels of large burden can unload. The castle, when seen from the bridge, has a stately appearance; but since the sessions have been held here, it has been greatly disfigured by part of it being converted into a county gaol. The walls are of great thickness. It was strongly fortified with towers, and is said to have been built by Gilbert Earl of Clare.

At a short distance to the south of the town, is a priory of black canons, endowed by Robert de Haverford, lord of this place. The walk to it from the town is pleasant, and the ruins have a venerable aspect. The chapel is the best preserved part.

The market here is one of the largest and most abundant in Wales, and fish are to be had in the greatest plenty and variety. There is likewise a very large corn market, and there is a great fair for horses and cattle on the 7th of July on St Thomas's day, who is the tutelary saint of the upper town. Near this town there is a cotton mill, which gives employment to about 150 persons. It is the principal manufacture in the county. A considerable number of independent gentry reside at Haverford. The town is a county of itself, and it sends one member to parliament, who is elected by freeholders and burgesses, and inhabitants not receiving alms, to the amount of 500. The inhabitants draw their chief support from travellers who go from Milford Haven to Waterford, Wexford, Cork &c.

The following is the population abstract for the town in 1811.

| | |
|---|---|
| Number of inhabited houses | 630 |
| Number of families | 691 |
| Do. employed in agriculture | 32 |
| Do. employed in trade and manufactures | 290 |
| Males | 1257 |
| Females | 1836 |
| Population in 1811 | 3093 |
| Increase since 1801 | 213 |

See Malkin's *Scenery*, *Antiquities*, and *Biography of South Wales*, vol. ii. chap. 26. p. 293.

HAVRE de Grace is a seaport town of France, in the department of the Lower Seine. It is situated at the mouth of the river Seine, in a marshy soil, intersected with creeks and ditches. It is defended by lofty walls, and ditches furnished with sluices, and has a citadel with bastions, which is one of the most regular in the kingdom. It contains two churches, an hospital, poors-house, arsenal, magazines, and storehouses, for the construction and manning of ships. There are no fewer than forty streets, adorned with six fine fountains. Four of these streets terminate in the great square. The harbour, which has a long pier connected with it, is capable of containing from 600 to 700 vessels. It has a depth of water sufficient to hold ships of war of 60 guns. There is here a fine dock-yard, several rope-works, and manufactories for tobacco, lace, starch, vitriol, earthen ware, paper, tiles, and bricks. The tobacco manufactory was established by the French East India Company, and at one time there were 60 tables furnished with a wheel, and attended by seven persons. Each of these made 90 pounds of tobacco in a day, and, including Caudebec, Harfleur, and Fecamp, the annual value of this manufacture was 170,000 francs. It has, however, greatly declined, but still employs about 400 workmen. The rope-works were lately eight in number. There is here also a refinery of sugar, and another of oil, both for burning and painting.

In time of peace, Havre carries on a great trade with the United States of America and the West Indies, and takes a great share in the herring and whale fisheries. About 600 vessels used to return loaded with the merchandise of other countries; viz. 60 from Martinique, 18 from Newfoundlandland, 40 from Marseilles, 65 from the coast of France from Bayonne to St Malo, 10 from St Maurice, 15 from Lisbon, 20 from Holland, 260 from England, and more than 60 from other countries of the north.

Havre was founded in 1509 by Louis XII.; and, after the battle of Marignon, Francis I built a large tower to defend the harbour, and gave it the name of Franciscopolis. The walls of the harbour were scarcely begun, when an irruption of the sea destroyed about two-thirds of the town, and almost all the inhabitants, on the 15th January 1525. Twenty-eight fishing boats were carried into the ditches of the castle of Graville. Population 19,500. East Long. 0° 6′ 38″; North Lat. 49° 29′ 14″.

HAWARDEN, commonly called HARRADEN, or Hording, is a town of North Wales in Flintshire. It is a thriving place, and is situated on a small river running into Chester New Channel. The streets are well paved, and the houses well built. The church is a plain good building, and is remarkable only for having an annual revenue of about 3000*l*. Between the town and the river Dee, the remains of the castle of Peny Llwch stands upon an eminence. It was a place of great strength, and is supposed to have been built before the Norman conquest. It was demolished by order of the Parliament in 1680. By the exertions of the Glynne family, the form of the castle has been rendered visible, by the removal of great quantities of rubbish. It seems to have been of a pentagonal shape, with a strong square entrance gateway. The keep, or citadel, consisting of a circular tower, nearly entire, was placed at an angle. The deep ditches now form picturesque ravines filled with fine trees. On a mount, called Freeman's Hill, to the west of the church, are traces of an encampment; and at the distance of about two miles from the town, are the remains of Culo castle, a double fortress, with a square area and two round towers. They stand on the edge of a deep wooded dingle, and are covered with ivy. In the neighbourhood of the town, particularly near Buckden hill, there is a manufactory of earthen ware. There is also a large iron foundery, from which articles of cast and wrought iron are sent to Chester, and thence to different parts of the kingdom. Hawarden Park, the seat of the Glynne family, is near the town. The house, built in 1752, is a handsome structure.

The population of the town and parish, in 1811, was—

See Pennant's *Tour in Wales*, vol ii. p. 88. 92; and *The Beauties of England and Wales*, vol. xvii. p. 672—683.

HAWICK, is a town of Scotland, in the county of Roxburgh, situated at the confluence of the rivers Tiviot and Slitrig, on the west road between London and Edinburgh. It is distant from Edinburgh 47 miles, from Carlisle 44, and from Berwick 42. The river Tiviot runs close by the town, and the Slitrig runs through it, dividing it into two nearly equal parts, which are connected together by two stone bridges, one of which bears evident marks of antiquity. In August 1767, the Slitrig suddenly rose to a great height, occasioned by a cloud bursting at its source, and in its course swept away fifteen dwelling-houses and a corn-mill. Hawick is a burgh of barony of very ancient origin. It is independent of the superior, and enjoys almost all the privileges of a royal burgh, except that of sending a representative to parliament. The date of its original erection into a burgh of barony is not known, the records of the burgh having been destroyed, and the town itself repeatedly burnt, during the Border wars between the English and the Scots; the last instance of which occurred in the reign of Queen Elizabeth, in the year 1570, and is recorded by Stowe, in his *Chronicles of England*, who says—"The seaventeenth of April, the Earle of Sussex, lieutenant-generall in the North, with the Lord Hunsdon, lord governor of Barwike, and warden of the east marches, and Master William Drewry, high marshal of Barwike, with all the garrison and power of the same, began a journey into Scotland, and the same night came to Warke, twelve miles from Barwike, and so the next morrow entered into Tividale; and, marching in warlike order, they bīet, (burnt) overthrew, rased, and spoyled all the castells, towers, and villages of their enemies, till they came to the castell of Mosse, standing in a strōg marish belōging to the L. of Buckcluch, which likewise was rased, overthrowne, and brent, and so marched forward, and brent the whole countrey before them till they came to Crailing." After mentioning a great many other places which they burnt, Stowe proceeds thus—"The nineteenth, the armie divided into two partes, the one parte whereof passed the river of Tivite, and brent the castell of Ferniherst, and all other castells and townes belonging to the Lord of Ferniherst, Huntill, and Bedrell, and so passed to Mint, where both the armyes mette agayne, and so brent on bothe sides the river, till they came to a *greate towne called Hawike*, where they intended to have lodged; but the Scottes had unthatched the houses, and brent the thatch in the streetes, and themselves fledde with most parte of theyr goodes; but, by the industrie of the Englishmen, the timber was also burned with the thatch, saving one little house of stone of Drumlanricke's, wherein my lord lay that nighte."

Drumlanricke's little house of stone is supposed to be that which is now the Tower Inn, belonging to his Grace the Duke of Buccleuch, which has long been celebrated for the excellent accommodation afforded to travellers. The walls of the oldest part of this building are, in some places, no less than seven feet thick. It has been lately very considerably enlarged, and is now one of the most commodious inns in the south of Scotland. The oldest charter of the town now extant, is a charter of confirmation granted by James Douglas of Drumlanrick, then baron of the barony of Hawick, in 1537, which declares the town to have been from of old a free burgh of baronie, and proceeds on the narrative, that "the charters and evidents of the said town and burgh, through the inroads of the English and thieves in the by past times of enmity and war, had been lost and destroyed;" and this charter imposes on the grantees thereof the singular burden "of maintaining one lamp or pot of burning oil before the great altar of the parish church of Hawick, in time of high mass and evening prayers, on all holidays throughout the year, in honour of our blessed Lord and Saviour Jesus Christ, for the souls of the barons of Hawick, founders of the said lamp, and their successors." This charter was confirmed by a royal charter, granted by Queen Mary in 1545. The church is beautifully situated on a circular eminence in the middle of the town, and the church-yard commands a fine prospect of the surrounding country. The town is well paved and lighted, and has a plentiful supply of excellent spring water, which is conveyed to the town in leaden pipes. It has a respectable town-house, in which the burgh and justice of peace courts are held. A new line of road is just now making to the town from the west, which will form a fine approach, and already a very handsome new street is begun to be built along the sides of it. At the west end of the town there is an artificial mound of earth, of a conical form, of considerable height, called the *Mote*, which, according to tradition, was formerly used for holding courts of justice. The mail coach from London to Edinburgh, by Carlisle, passes through the town every day, and it is at present (1816) in contemplation to establish a mail coach between this place and Berwick. The town is governed by two bailies, who, with the advice of the town council, have the sole management of the revenues and affairs of the burgh. The bailies are chosen annually, by a poll of the resident burgesses. The town council is composed of 15 standing councillors, so called from their continuing in office during life, who are elected by the bailies and standing council: and of 14 trades councillors, or quarter-masters, who are chosen annually, two by each of the seven incorporated trades of the burgh. Its revenue, which consists chiefly of the rents of a large common belonging to the burgh, is about 400*l.* per annum. The poor of the town and parish are supported by a rate, one-third whereof is paid by the proprietors within the burgh, and two-thirds by the heritors and tenants of the landward part of the parish. Besides the established church, there are three places of religious worship in the town, viz. the Burgher, Antiburgher, and Relief meeting houses. There is an excellent public library in the town, which was begun in 1760. There was also lately established a subscription library, by the tradesmen of the place, and there are besides two or three circulating libraries. A branch of the British Linen Company Bank has been long established here, and a savings bank was instituted in January 1815, in which there was deposited, during the first year, 870*l.*, by 183 different individuals. In 1776, a farming club was instituted in Hawick for the discussion of questions connected with agriculture. It is composed of most of the respectable farmers, and several of the landed proprietors of the district. This club holds its meetings regularly on the first Thursday of every month. It is believed it was the first association of the kind established in Scotland, and it has the merit of having originated many very important improvements connected with agriculture. There is here a weekly market on the Thursday, and four annual fairs, which fall on the 17th May, 17th July, 21st September, and 8th November, besides a cattle tryst, at which considerable numbers of black cattle are presented for sale in passing from Falkirk tryst to Newcastle and Carlisle fairs. In 1811, the population of the town amounted to 3036, and the town contained 349 inhabited houses. Since that time no census has been taken, but the population and number of houses during the last five years has very considerably increased; and at present, in 1816, (including the population of Damside in the adjoining parish of Wilton, which may be reckoned the suburbs of the town,) it is estimated to exceed 4000. There are in the town three skinneries, one tannery, and two breweries; and a very considerable trade is carried on in the manufacture of carpets, lambs wool stockings, Scots blankets, thongs, and gloves. The manufacture of lambs wool stockings, in particular, from the introduction of machinery, has of late years made very rapid progress, and is still on the increase; it was first begun in 1771. In 1791, there were manufactured only 3505 pairs of lambs wool stockings, and 594 pairs of cotton, thread, and worsted hose. The number of persons then employed in the trade was 14 men, and 51 women, who were chiefly employed in spinning the yarn. The yarn, however, is now all spun by machinery. There are at present employed for this purpose 7 carding mills, which all go by water, containing 44 engines, or scribbling and carding machines, 100 spinning jennies, and upwards of 500 stocking frames. The greatest part of the spinning jennies are at present wrought by the hand; but jennies of a new construction, to go by water, have, within the last twelve months, been introduced with success into four of the carding mills. The quantity of wool annually spun into yarn is upwards of 12,000 stones, of 24 lbs. to the stone, three fifths of which are manufactured into stockings, and the other two fifths sold in yarn to manufacturers in other parts of the country, for the purpose of being made into stockings. The quantity of stockings annually made by the manufacturers in the town exceeds 328,000 pairs. The number of persons in the town and neighbourhood employed in the different branches of this manufacture, is about 1000. This place has been long celebrated for its extensive nurseries, carried on by Archibald Dickson & Sons here, and at Hassendeanburn in the vicinity, where they were first begun in the year 1729. The nursery grounds in the occupation of these gentlemen now extend to upwards of 100 acres, cropped with all sorts of foreign and native forest and fruit trees, flowering shrubs, and evergreens, &c. These nursery grounds are very ornamental to the place, extending along the side of the turnpike road to the east and west of the town, for the distance of upwards of a mile and a half. In the cropping and cleaning season, they afford employment for not fewer than 90 men, women, and children; but at other seasons men only are employed in them. A very extensive business in the seed line is also carried on by A. Dickson & Sons. The position of Hawick, as estimated from Captain Colby's observations on Wisphill, is North Lat. 55° 26′, and West Long. 2° 47′.

HAWK. See Hawking and Ornithology.

HAWKES' Temperaments of the musical scale. In the years 1798, and 1805, Mr William Hawkes published two pamphlets for recommending the adoption of an irregular douzeave scale, wherein 9 of the Vth, viz. upon C, G, D, A, E, B, ♯F; and upon F and ♭B should each be flattened $\frac{1}{5}$th of a major comma, or be of the value $355.7984272\Sigma+7f+31m$; two of the Vths, viz. on ♯C and ♭E perfect, or each $=358\Sigma+7f+31m$; and consequently, the resulting or wolf Vth, on ♯G, $=365.8141552\Sigma+7f+30m$. Many particulars concerning the notes and temperaments of which system, may be seen in the *Philosophical Magazine*, vol. xxvi. p. 173; xxviii. p. 304; xxx. p. 5;

xxxvi. p. 47; and vol. xxxvii. p. 129, in which last page the *beats* of each of its 68 tempered concords are calculated, by Mr John Barraud, brother to the chronometer maker.

In 1807, Mr Hawkes contrived, and in 1808 took out a patent for his methods of extending the scale of organs and piano-fortes to 17 notes in the octave, (see the *Phil. Mag.* vol. xxxvii. p. 325); and in 1810, he published a third musical pamphlet, in which his object (as afterwards explained by letter to Mr Farey, see *Phil. Mag.* vol. xxxvii. p. 321.) was to recommend, for the tuning of this his patent instrument, a regular dixseptave system, in which 16 of the fifths, viz. on C, G, D, A, E, B; ♯F, ♯C, ♯G, and ♯D; and on F, ♭B, ♭E, ♭A, ♭D, and ♭G, should be each flattened the 1-318th part of the octave, (or $\frac{1}{6}$th of Mercator's comma), or each of the value 356.068514Σ+7f+31m, and the resulting or wolf fifth ♯A to F, is of course =367.246346 Σ+7f+30m. The *beats* of each of the 102 concords in this system, have been calculated by the Rev. C. J. Smyth of Norwich, and published in the *Phil. Mag.* vol. xxxvii. p. 323, to which table we shall refer instead of copying it; because from Mr Liston's *Essay on Perfect Intonation*, p. 23. and 142. it appears, that Mr Hawkes has since (by letter to Mr Liston we have been informed) changed his former opinion, and now recommends the Vths for his patent instruments to be flattened $\frac{1}{6}$ of a major comma, in which terms Mr Liston has given its temperaments in p. 22. It may be proper, however, to add, that, in this new system, each of the 16 fifths above mentioned, will be =356.165356 Σ+7f+31m, and the wolf fifth on ♯A =366.181084Σ+7f+30m.

Mr Hawkes' patent piano-fortes are furnished with 24 strings in each octave, although 17 only are of different sounds, that is, all the long keys have two unison strings, from one to the other of which the hammers shift, at the same time that they do so from the 5 short-key notes tuned *flats*, to the five others tuned *sharps*, or *vice versa*; it seems, however, to us, that 7 of these strings might probably be dispensed with, by allowing rather more space on each side the long-key strings A, B, C, D, E, F, and G, and making their hammers rather wider, so that after the shifting sidewise of the key-board necessary to cause the short-key hammers to move from ♯A, ♯C, ♯D, ♯F, and ♯G, to ♭B, ♭D, ♭E, ♭G, and ♭A respectively, or *vice versa*, the hammers of the long-keys may still continue to strike the same strings.

The objections which were so forcibly urged in Dr Kemp's *Musical Magazine* against the defect of these instruments, in not being able to give *flat* and *sharp* notes at the same time, or quickly succeeding each other, as composers not unfrequently direct, seem to operate fatally against their introduction to general use. We have lately heard, that the organ which Mr Hawkes caused to be put up, a few years ago, in Christ Church, Blackfriars Road, in Surrey, has been either removed or altered to a common organ. We are aware, however, that this may have arisen from injudicious attempts at tuning this organ, according to one or other of the systems that we have mentioned in this article, instead of applying the Mean Tone *System*, which alone, or one exceedingly near to it, (in the perfection of its major third), seems applicable to this noble instrument. (ϱ)

HAWKING, or Falconry, is the art of catching wild fowls by means of hawks, or other birds of prey, tamed, and properly tutored for that purpose.

The art of falconry appears to have been known both to the Greeks and Romans. It was in high repute in almost every part of Europe during the 12th century, but after the invention of fire arms, it gradually declined.

Mr Pennant has not been able to find any accounts of the art of falconry in England before the year 760, in the reign of King Ethelbert, who sent to Germany for a brace of falcons that would fly at cranes. The art was much practised till the Usurpation, when it fell into disuse.

The birds which are generally trained to this art, are the jer-falcon, the pergrine, and the goshawk. By starving them, and keeping them awake, and never leaving them alone, they are rendered quite tame; and, by a regular system of severe instruction, they become so familiarized to the falconer, that they obey all his commands. They are taught to settle on his fist, to spring at game, and to bring back the prey to the falconer. For an account and other particulars of the history of falconry, see Beckmann's *History of Inventions*, vol. i.; and Shaw's *General Zoology*, vol. vii. part i. See also Ornithology.

HAYMAKING. See Agriculture.
